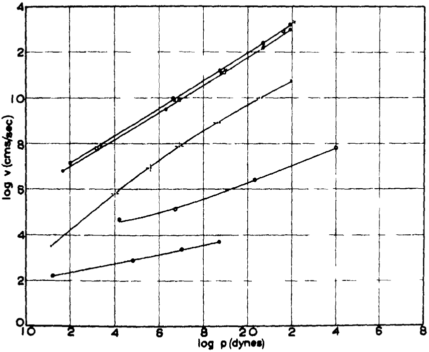
RECENT measurements on the flow of liquid helium II through capillaries have yielded very varied results We reported earlier[1] that the flow through long capillaries bore no relation to a normal laminar or turbulent condition of the liquid and that the velocity depended only slightly on the pressure head



Capillary length	T°K	Capillary length	T°K
☐ 6 mm	2 164°	✕ 6 mm	1 161°
◉ 11 5 mm	2 164°	• 11 5 mm	1 161°
● 40 cm	2 164°	▫ 40 cm	1 161°
┼ 11 5 m	2 2° (helium I)		

Since that time we have made many further observations on flow through capillaries varying in radius from 0 05 cm down to 6 × 10^{-5} cm, as well as through tubes filled with tightly packed rouge The smallest capillaries were produced by drawing down german silver tubes closely packed with fine stainless steel wires The full details will be published elsewhere but the main results are as follows

(i) The rate of flow in all cases in capillaries more than 15 cm in length depended only slightly on the pressure head (ii) The smaller the cross sectional area of the capillary the more independent of head did the velocity become For the finest capillaries the flow became completely independent of head for all pressures from zero to 200 dynes (iii) The pressure independent velocity increased very rapidly between 2 177° K and 1 15° K

Although Kapitza[2] was only able to observe turbulent flow Burton[3] and Giauque Stout and Barieau[4] in recent papers, have recorded laminar flow in helium II and suggest that the type of pressure independent flow which we have observed might be due to the transport of liquid in surface films such as have been observed by Daunt and Mendelssohn[5] In all our experiments precautions were taken against such a flow For some of the measurements on the larger capillaries a reservoir was used which was completely closed except for the capillary opening When open reservoirs were used, they were invariably made with constrictions 1 mm in diameter at the top thereby reducing the surface transport In these cases duplicate reservoirs with no capillary attached and closed at the bottom were fastened side by side with the flow reservoir The correction for the flow due to surface films was usually less than one per cent and for the finest capillaries was not greater than seven or eight per cent

Since the above results might appear to be in conflict with those of Burton[3] and Giauque[4], we have made some measurements under experimental conditions similar to Burton s A reservoir diameter of 16 mm and a capillary diameter of 0 03 cm was used, and observations were made using three different lengths 6 mm, 11 5 mm and 40 cm The results are shown in the accompanying diagram Logarithmic curves are given for two measuring temperatures in helium II, and in the case of the 11 5 mm capillary for a temperature in helium I of approximately

2 2° K In no case in helium II was a purely laminar flow observed, although in the case of the two shorter capillaries the curves might indicate a semi turbulent condition If we assume the flow to be laminar and calculate the viscosity from Poiseuille s formula, we obtain a value of 7 8 × 10^{-6} c g s units with $R = 280$, which agrees with Burton s value for a capillary of somewhat the same length On the other hand shortening the capillary length to 6 mm appears to have very little effect on the velocity and lengthening the capillary to 40 cm has the effect of decreasing the velocity only by a factor of five at 2 160° K Lengthening the capillary also has the effect of making the velocity much more independent of pressure It is noted that although the velocity through long capillaries increases with decreasing temperature, the velocity through the shorter capillaries actually decreases by about 5 per cent from 2 160° to 1 165° K For purposes of comparison a measurement of the flow in helium I, just above the λ point, was made The flow was observed to be laminar for low velocities and turbulent for high velocities The viscosity was found to be 1 4 × 10^{-4} c g s units which is in fair agreement with previous measurements

Effect of Collisions on the Intensities of Nebular Lines

THERE appears to be a widespread misconception concerning the effect of electron collisions on the intensities of forbidden lines The prevailing view appears to be that, at high densities collisions of the second kind operate to de excite atoms from the metastable levels before the atoms have a chance to radiate, and that only at low densities as in the gaseous nebulæ, can a sufficiently high population of atoms be obtained to give appreciable intensity to the forbidden lines The mathematical reasoning advanced to support this argument[1] is as follows Let N_1b_{12} be the number of atoms excited per second from the ground to the metastable level by inelastic electron impact which process is ordinarily assumed to be the predominant source of excitation Let N_2b_{21} be the number of super elastic collisions per second Let A_{21} be the Einstein probability of spontaneous emission Then the intensity of the line may be written

$$I = \frac{N_1 b_{12}}{b_{21} + A_{21}} A_{21} h\nu \tag{1}$$

The customary argument is that the increase of b_{21} with density causes the value of I to decrease

The fallacy in the reasoning lies in the fact[2] that the excitation coefficients, b_{12} and b_{21}, both being proportional to the electron density, keep exactly in step Furthermore, they are closely related, so that one may be expressed in terms of the other Equation (1) is easily transformed to the following equivalent expression

$$I = N_1 \frac{\bar{\omega}_2}{\bar{\omega}_1} e^{-h\nu/kT} \left(\frac{1}{1 + A_{21}/b_{21}}\right) A_{21} h\nu, \tag{2}$$

where the $\bar{\omega}$ s refer to the statistical weights of the respective levels Since practically all the atoms are in the lower level, we may regard N_1 to be the total number of atoms in the assembly The first factor represents a Boltzmann distribution, which would be accurately attained if A_{21} were zero The second factor, enclosed in parentheses, is always less than unity A_{21} is an atomic constant I reaches a maximum when $b_{21} \gg A_{21}$, that is, when the electron density is *high* This conclusion is the reverse of that stated in the first paragraph

Part of the misunderstanding may arise from the erroneous belief that if the probability of collisional de excitation is greater than the probability of emission, the atoms do not have time to radiate This reasoning would imply a difference between an atom that arrived in a metastable state 10^{-6} seconds ago and one that may have existed in that level for some seconds The argument would imply that the quantum equation

$$I = N_2 A_{21} h\nu \tag{3}$$

is wrong The intensity depends solely on the population and atomic constants and the highest intensity occurs when N_2 is greatest

When equation (2) is applied to the normal lines with high values of A_{21} we discover that serious departures from thermodynamic equilibrium, with consequent fading of permitted lines, may be expected at densities from 10^6 to 10^8 times greater than for the forbidden lines Where, in a nebula, the forbidden lines may occur with intensities not far from their thermodynamic values, the permitted lines will have their intensities greatly decreased from the laboratory values The predominance of the forbidden lines in nebular spectra, therefore, is attributable, not *to the effect of collisions in de exciting an atom* before it has a chance to radiate but to the weakness of the permitted lines The high absolute intensity of the forbidden lines is explicable only in terms of the large total mass of the nebulæ The predominance of normal lines in laboratory spectra is due chiefly to the high values of the associated Einstein A's, though collisions of excited atoms with the cool walls of a tube, an essentially irreversible process, may affect the relative intensities

The foregoing analysis can be extended to atoms with more than one excited level One may also show that removal of the atoms from the metastable levels by radiation processes does not result in an appreciable lowering of the level population, in contradiction to the results of Eddington[3]

Note added in proof (Sept 19) Kaplan[4] reports that certain forbidden lines, observed in the nitrogen afterglow, drop in intensity as the pressure goes down He remarks, 'Since these radiations originate in relatively forbidden transitions, it is of considerable astrophysical interest to report an increase in intensity with pressure rather than the expected decrease " The observational proof of the points raised in the foregoing letter seems to be already available

REVIEWS

Audubon

Audubon, the Naturalist:
a History of his Life and Time. By Prof. Francis Hobart Herrick. Second edition, two volumes in one Pp xcii+451+500+56 plates (New York and London: D Appleton-Century Co, Inc, 1938) 25s net

THIS work may be described as the standard biography of Audubon, from which the lighter and more romantic versions which have appeared from time to time have largely been drawn. It is strange that a life so full of genuine romance and adventure, a personality so individual, magnificent alike in stubborn courage and childlike carelessness and candour, should fail to satisfy the appetites of so many biographers without the added condiment of a fictitious royal birth Prof Herrick's careful account of Audubon's early life, in the first edition, would seem to have settled the matter; but subsequent publications have again promulgated the wild hypothesis that the poor fragile Dauphin and the vigorous naturalist were one and the same certain members of the Audubon family were drawn to the idea, disliking the illegitimate and Creole birth of their ancestor Prof. Herrick's new foreword and postscript must convince all but the wilfully credulous

The first part of the book deals with the life-history of Audubon from his birth and adoption, his short period in a naval college, his abortive studies in the studio of the celebrated David, his emigration to America, his many struggles in business, and the two fixed points in the kaleidoscope of his life—his great wife Lucy and his dominating passion for birds and beasts and for their portrayal. Such business ventures as he made, even to portrait painting and the teaching of dancing, were all undertaken so as to get means for pursuing this, his chosen work, his Lucy loyally bore privations and separations, and her self became a paid worker, so as to help to provide for their children, and to ensure the fame and recognition which she never doubted

In the next section—Audubon the naturalist—we have the account of his various explorations, extracts from his diaries, certain aspects of the controversies in which this pioneer ornithologist and artist was involved, sidelights on his contemporaries, the account of his ultimate triumph and recognition, and his subsequent work, aided now by his sons There are several appendixes · original documents, birds of America, likenesses of Audubon, a very full bibliography, and that most useful feature, a careful index

The illustrations include likenesses of relations and contemporaries, scenes from the homes of Audubon and many reproductions of his pictures, from the early simple drawings to the splendour of the decorative colour plates. This great innovation, namely, the representation of birds and animals in life and motion, in something approaching natural habitat, obtained favour in America only after England, Scotland and France had recognized its charm and value Prof Herrick does not omit to pay tribute to the great part played by Havell, the engraver. The large size of the plates, some of no less than five square feet, entailed the most skilful combination of aquatint with etching and line engraving It was indeed fortunate that the pioneer artist and naturalist should have found a coadjutor of like courage and enterprise.

In biography, romance makes a good servant, but a bad master, and it is well to have this scholarly and critical presentation of a personality and life-history so unusual as almost to invite exaggeration.

The English 'Open Field' System

The Open Fields
By C S and C S Orwin Pp xii+332+29 plates (Oxford Clarendon Press, London Oxford University Press 1938) 21*s* net

THE layout of the countryside of England as we see it to day is a very recent development even the strict four course rotation that in many places preceded it and which is often regarded as the real old English system of farming, lasted but little more than a century The system that had the long life in England was the one associated with the open fields It comprised two distinct features sub division of the land among those entitled to share in it, and a rotation which usually consisted of winter corn spring corn fallow it is thus described by Tusser in 1573

First rie and then barlie the champion saies
Or wheat before barlie be champion waies
But drinke before bread corn with Middlesex men,
Then lay on more compas and fallow agen

Although the land was very much sub divided the cropping appears to have been usually con solidated and the total area of arable land of the village was set out in three fields, each devoted wholly to one part of the rotation Each field was divided into small areas which were allocated to those entitled to receive them, but each man's holding was scattered over all three fields each could, therefore in principle, receive his share of good and of poor soil The land was left open, unenclosed by hedges the system is therefore called the 'open field system' and the process of bringing it to an end was called 'enclosure'

Mr and Mrs Orwin have rendered splendid service to all interested in the history of the countryside by drawing up a full and detailed account of the working of the system in the ancient Nottinghamshire village of Laxton of which, fortunately unusually full records have been preserved and where indeed part of the system still survives Their book thus becomes valuable source material, and the copious extracts from the old documents and a complete transcription of the "Booke of Survaye" of 1635, give it unusual value for those who wish to acquire more than the usual sketchy knowledge of the subject

Experts will be particularly grateful for the useful account of the management of grazing for livestock under this system Grazing was, of course very inadequate, and much slaughtering and salting down had to be done round about Michaelmas, because there would be no food for the animals during winter to quote Tusser again

At Hallowtide, slaughter time entereth in,
And then doth the husbandman's feasting begin
From thence unto Shroftide kill now and then some,
This offal for houshold the better wil come

But it was always obvious that some provision had to be made for what farmers call winter keep' and the authors show how this was done

The extensive quotations from the records of fines throw valuable light on the agricultural and general life of the village indeed the whole range of country life in England in the seventeenth century is illuminated by the well chosen extracts

The origin of the system is still obscure Part of the system the sub division of the land and the scattering of the holdings, was widely spread around the Baltic it is still in use in Poland, it has not long been displaced in Russia, also it is still practised in Northern India The rotations also showed some resemblances to those used in England, but consolidation of cropping was not so common, and is not usual either in Poland or Northern India, except where some special circumstance has necessitated its adoption

The system had the advantage of permanence, and there is no evidence of soil deterioration throughout all the years that it was practised Also it accorded with the peasants' fundamental rule of husbandry, 'safety first' for if the crop on one of his strips was bad there was always the possibility that the yield on another might be better But it had the grave disadvantage that yields were low and improvements extremely difficult only when the scattered holdings were brought together into one piece could better methods be used In England this process of consolidation began in Tudor times, and was continued almost to our own day In Russia it was achieved after the Revolution under the name 'collectivization' in Poland, France (where necessary) and India it goes on more gradually and by persuasion

The system can find no place in modern country life It belongs to the old village life the days of the craftsman, of folk dances and folk songs, of the old feasts and fairs, but it has passed One cannot regret it, because it could not produce food in sufficient quantity or variety to maintain the village population in health But it has left its mark deeply on the countryside indeed the plan of the village to-day is frequently in the main lines almost the same as when the system was in operation E J RUSSELL

Growth of Astronomical Thought

A Hundred Years of Astronomy
By Reginald L Waterfield (The Hundred Years Series) Pp 526 (London Gerald Duckworth and Co Ltd 1938) 21s net

MR WATERFIELD has undertaken a very heavy task and has produced an interesting and useful work There are especially in the United States many text books of descriptive astronomy with formulæ diagrams and (some times) excellent illustrations This is something quite different Its production has evidently entailed a very considerable amount of research into historical questions and yet it is not by any means purely a history The layman will probably feel after a first reading that there is an astonishing amount of astronomy of which he had scarcely heard but which appears on the whole to be within his powers of comprehension and is fascinating in its interest once it is grasped For the author has set out to describe not merely the development of knowledge but also the development of understanding he sketches the processes of thought the conflicting evidence the puzzles and their solution (when it has been attained) and he outlines present knowledge and speculation in a very readable way Such a question as the motions of the stars as a whole might seem poorly suited to exposition for the lay mind with no formulæ and practically no technical terms allowed but by an apt use of analogies from everyday life Mr Waterfield does in fact hold the various classes of motion distinct in the reader s mind and guides him if he has a reasonably strong determination to follow through a maze that was largely uncharted even by professionals at the start of the present century

Mr Waterfield is an amateur astronomer and astronomy is pre eminently the science in which amateurs always have distinguished themselves On topics that usually interest amateurs most he may be taken as authoritative such matters as physical observations of the planets the behaviour of long period variables and the construction of telescopes may fairly be expected to be competently handled and in fact dynamical and statistical astronomy are at least as well treated It must however be added that he is less sound on the details of astrophysics atomic theory and also fundamental astronomy The errors are as a rule not of a nature to damage the whole presentation seriously but they are more numerous than one would wish

The book also suffers from some defects in arrangement especially in the earlier chapters. The author describes it himself as at first sight somewhat chaotic and it must be said that it does not improve with acquaintance Wireless Time Signals and Stellar Evolution is perplexing as a chapter heading so is Solar Physics and the Motions of the Stars The arrangement is apparently due to an attempt to group together questions that arose at the same time but even so the author is not consistent since Stellar Evolution is allowed to run right on to the latest developments in curved space The later chapters are better in this respect There are other signs of inadequate revision but it should perhaps be said that the author can in fact plead that at the time he was seriously hampered by circumstances beyond his control

Perhaps in a second edition which it is much to be hoped will be called for these superficial blemishes may be rectified The book as a whole is altogether too good to be judged by its defects

Vanishing Tribes of India

The Travancore Tribes and Castes
By L A Krishna Iyer Vol 1 Pp xxi + 277 + 60 plates (Trivandrum Government Press 1937) 7 rupees

IT was the ardent wish of that veteran ethnologist L K Anantakrishna Iyer to complete the survey of South India with volumes on Coorg and Travancore His work in Coorg was cut short by his death and it is fitting that the Travancore Survey should be entrusted to his son Wisely the Travancore Government decided that first attention should be given to the hill tribes whose social and religious institutions are fast vanishing Only seven of these tribes are dealt with in this volume which repeats and amplifies the admirable synopses of the Census Report for 1931 based on the author s notes

Of the seven tribes three are assumed to be offshoots of Hinduized communities well known in the plains the Kuravans the Pulayans and the Vedans The Hill Pandarams who number only

187 souls may be kinsmen of the Paliyans of Madura and Tinnevelly the most primitive folk in South India Of very different status are the Kanikkars of South Travancore a well knit community more than 6 000 strong with a wealth of traditional lore the Mannans of the Cardomom Hills (1 276) and the Hill Arayans in the woodlands to the west of them (3 182)

The pivot of tribal life in India—social economic and religious—is the clan (*illam* house in Malayalam) a group of families so closely related that marriage between them is considered incestuous brothers they are called (*annan tambi*), as distinguished from in laws (*machambi*) groups with whom marriage is permissible Sometimes the marriage law is simplified by grouping the clans into moieties each of which must take its brides from the other The limits of the marriage circle and prohibited degrees may vary from time to time and from place to place but the distinction between brothers and in laws is clear cut

Thus the clan lists of the Kanikkars differ in the five different areas for which they are recorded yet most of the clan names are common to more than one locality and in each area they are grouped into moieties Similar social patterns are found among the Mannans and among the Arayans Kuravans and Vedans of the hills

Mr Krishna Iyer s account of the clan systems of these people with their local variations is a big advance on the hasty generalizations of his predecessors but the picture is far from complete Evidence is lacking of the relations of the Kuravans and Vedans of the hills with their namesakes in the plains of the Pulayans Pandarams Kanikkars and Mannans with their kinsmen and neighbours across the border in British India The map reprinted from the Census Report excellent so far as it goes shows but a fraction of the places named in the text a separate map for each tribe is essential

It is to be hoped that in future volumes greater care will be taken with proof reading and the transliteration of proper names and with the printing of the plates

Civilization spells ruin to these tribes The drop in tribal religions from more than 28 000 in 1901 to less than 3 000 in 1931 is not solely due to deaths a few of the tribesmen have turned Christian the majority are now registered as Hindu It is their solidarity that is decaying the social autonomy which controls morality and is the traditional right of every Indian community The Travancore Government are alive to the problem with the facts now before them they may stop the rot F J R

Foundations of Nutrition

(1) The Foundations of Nutrition
By Prof Mary Swartz Rose Third edition Pp xi +625 +2 plates (New York The Macmillan Co 1938) 15*s* net

(2) A Laboratory Handbook for Dietetics
By Prof Mary Swartz Rose Fourth edition Pp xi +322 (New York The Macmillan Co 1937) 12*s* 6*d* net

(3) Food Tables
By Prof V H Mottram and Dr Ellen M Radloff Pp 63 (London Edward Arnold and Co 1937) 5*s* net

(1) WHETHER dealing with the early history or tracing the latest developments of the science of nutrition Prof Mary Swartz Rose s book The Foundations of Nutrition is a delight to read and distinguished by its clarity and vitality In these days of specialized work on the chemistry of foodstuffs, it is salutary to look back as Prof Rose has done

We tend to forget that Lavoisier and La Place made the first calorimeter and measured the heat evolved by animals and the oxygen consumption and carbon dioxide output in man With improved apparatus Regnault and Reiset discovered that in proportion to their size small animals use more oxygen and give out more carbon dioxide and heat than larger animals Next Bidder and Schmidt found that for every species of animal when no food is taken there is a typical minimum metabolism—our basal metabolism—varying with age size and sex Then followed Voit and Pettenkofer and Rubner who established the law of conservation of energy for the living body Rubner observed also the extra heat produced by food the greatest with meat—the specific dynamic action By means of perfected respiratory chambers Atwater Rosa and Benedict established the equivalence of *direct* calorimetry by heat measurement with *indirect* calorimetry calculated from the gaseous exchange Portable apparatus could then be designed for the easy measurement of energy metabolism Regarded as a machine man could have his energy expendi ture measured under every condition of life At rest and without food his basal metabolism averages 1 calorie per kgm of body weight per hour and is doubled by moderate exercise Unexpectedly, an hour s sweeping with a vacuum cleaner expends 2 7 calories per hour as compared with 1 4 with a hand broom and 1 6 with a carpet sweeper Such data make it possible to tot up the caloric expenditure of families and nations and to ration armies and civilian populations in emergencies

But food is not merely fuel for the engine Food in its relation to growth and health has to be studied separately One essential is protein Consideration must be given to the so called complete and incomplete proteins Experiments on man have shown that the daily requirement of mixed protein is 1 gm per kgm of body weight

Few books have such an admirable account of the mineral requirements of the body Most work on this aspect of nutrition has been done in the United States particularly by Sherman who recommends for the adult man 1 32 gm phosphorus 0 68 gm calcium and 15 mgm of iron per kgm of body weight per day Women during pregnancy and lactation and also children need much more Prof Rose prefers to give the quantities per 100 calories of food and shows pictures of portions of common foods which supply these amounts There are so many ways of expressing quantities that it is difficult to say which is the best

The thoroughness and impartiality with which the supply of each vitamin is considered is an example to those of our British dietitians who lavishly prescribe the fat soluble vitamins and provide the others in sub minimal amounts, especially neglecting vitamin B_1 the cheapest and easiest to provide Prof Rose is not content with their provision in anything less than the optimal amounts The chapters on vitamins are up to date Flavin is recognized as vitamin B_2 The latest finding of nicotinic acid as a cure for pellagra came too late for publication in the book

(2) and (3) Data of food analyses and calorie values are indispensable for the dietitian Prof Rose s Laboratory Handbook contains a summary of food requirements eleven practical examples in dietary calculations 250 pages of tables of figures and a helpful note on planning a dietetic laboratory

Food Tables by Prof V H Mottram and Dr Ellen Radloff gives in a handy form a collection of analyses of British foodstuffs Although these authors advocate the exclusion of figures beyond the decimal point they have not had the courage of their convictions and retain the original figures to three places of decimals

Both books include figures for the calcium phosphorus and iron contents of foods Prof Rose gives many vitamin values in Sherman units Mottram and Radloff prefer to wait until more vitamin values can be expressed in international units The data in these books represent years of tedious analytical work and innumerable calculations The student and dietitian now have all this labour done for them and should be duly thankful

With all this knowledge so easily available the obliging food manufacturer may in the future print on the labels of his cans the analyses calorie and vitamin values of the contents Eventually we may live on one perfect tin a day !

Plant Culture without Soil

Soil less Growth of Plants

Use of Nutrient Solutions Water Sand Cinder etc By Carlton Ellis and Miller W Swaney Pp 155 + 1 plate (New York Reinhold Publishing Corporation, London Chapman and Hall Ltd 1938) 13s 6d net.

THE growth of plants in liquid media instead of in soil is a method that has been much used in laboratory work for many years For experimental purposes the method has the great advantage of permitting close control of environmental conditions and of food supply, to a degree that is impossible when soil is used For some purposes the combination of nutrient solution with an inert substratum such as sand forms a useful modification Much of the conclusive work on the importance of trace elements in the economy of plants could scarcely have been carried out without the use of water culture methods

Comparatively recently attempts have been made to develop these methods from the commercial point of view A most expensive item in the glasshouse cultivation of crops is the periodical removal and replacement of the soil and it is claimed that growth in solution or sand culture would greatly reduce these costs if satisfactory equipment and technique could be evolved Californian workers state that considerable success has already been attained but so far as other countries are concerned the method is still in its preliminary stage It must be recognized that success in developing the necessary technique depends on the close co operation of skilled engineers and expert plant physiologists and as yet the ordinary commercial grower however skilful is not in a position to make an economic success of the method As it happens premature press publicity has attracted much popular attention and in some quarters has raised undue hopes of revolutionary crop production

Information on soil less growth is much scattered and C Ellis and M W Swaney have now provided a useful summary written primarily for the non scientific reader but embodying details of use to the biological worker The various examples quoted demonstrate the elasticity of the various methods but deal only with successful cultures tending to gloss over the possibility of failure At least one of the quoted culture solutions should have been omitted in an elementary work of this nature as concentrated acids are dangerous when used by inexperienced workers The assumption throughout the book that algæ and fungi are identical is inexplicable and misleading

One of the most useful features of the book is the demonstration that elaborate equipment and expensive chemicals are unnecessary for the amateur who desires to attempt a novel method of horticulture All kinds of vessels can be adapted for use and the nutrients obtained from any chemist The general outlines of the function of the major and trace elements in plant growth the action of hormones ethylene and plant stimulants and the notes on diseases and pests are all helpful to the non technical reader

It is much to be hoped that at a later date when a new edition is required the needs of the scientific worker and the large scale commercial grower will be met by a full discussion of the position with a frank and critical comparison of types of equipment and appropriate nutrient solution for the various crops There is no one optimum solution which can be maintained as a commercial secret and there is much to be gained by a general pooling of information in an attempt to ascertain whether the method of growth without soil has a real future from the commercial point of view as well as for fundamental laboratory investigation

---

Forest Management in Great Britain

Practical British Forestry
By C P Ackers Pp xviii+387+14 plates
(London Oxford University Press 1938) 15s net

THIS book bears the imprint of the practical man and is based on the experience of an owner of woodlands during thirty years of management of his own estates In his preface Mr Ackers alludes briefly to the training he went through to prepare himself for the work he has since carried out In a foreword Lord Clinton himself no mean forester in connexion with his own woodlands says It seems safe to predict that with the greater interest in forestry which is apparent to day a practical book upon the subject should meet with a very ready demand

Lord Clinton points out that there has always been a tendency to criticize the system of management as practised in Great Britain He admits that on many private estates no system exists and that often species are not suited to soils and environment In consequence the owner receives no regular income from the forestry portion of his estate and holds the opinion that forestry cannot pay The author tells us that from the outset he had to regard forestry as a purely business proposition He gives us an instance

I held the opinion and still do that the art of raising high class nursery stock has a bearing in many aspects on the problems of growing first class woodland produce I also felt that to do really well the grower should realize some of the tribulations and aims of the timber merchant With the object of correlating some of these ideas I now have 30 acres of commercial nurseries some 2 000 acres of commercially run woodlands and a sawmill utilizing some 1 000 cubic feet of timber a week The nursery and sawmill were formed with a minimum of capital and have to pay their way or be closed down

Space will not permit of following the author in great detail Following an introductory chapter two chapters are devoted to the hardwoods or broad leaved trees and conifers or soft wood trees the sylviculture of the most important species being treated in a general manner the chief pests being mentioned and the chief uses to which the timber is put Other chapters deal with damage by the elements vermin and so forth nursery work planting and establishing, thinning and pruning, extraction, conversion and sale of timber, sylviculture, minor forest produce and miscellaneous, in which various forestry operations are discussed, and a chapter entitled 'The Future" in which such matters as taxation on forestry lands, conservation of our forest resources, future supplies, and so forth, are dealt with

It is a pity that the author should have discussed working plans (Chapter xl, in Miscellaneous), the preparation and *raison d'être* of which he obviously misunderstands A working plan for a forest area is not necessarily confined to Universal High Forest", nor are working plans of necessity subject to 'regular fellings of areas identical in acreage year in year out decade after decade century after century" The provisions of a working plan are drawn up as the objects of management of the owner, whether State or private proprietor, prescribe A plan can be prepared for 100 acres of coppice with an annual or periodic yield, as well as for high forest on a long rotation The object of placing an area of woods under the provisions of a working plan is to safeguard it from the possibility of irregular fellings when money is wanted and poor management which produce the state of affairs the author's book is designed to improve

Mr Ackers is to be congratulated on his treatment of Sport and Modern Forestry' (Chapter lx) It is possibly the best exposition of a widely misunderstood subject amongst landowners in this country which has ever appeared in a modern book devoted to British forestry

---

Science and Practice of Brewing

Brewing Science and Practice
Vol I Brewing Materials By H Lloyd Hind Pp xiv + 505 + 27 plates (London Chapman and Hall, Ltd, 1938) 50*s* net

A LONG STANDING hiatus in English scientific and technological literature would seem to have been filled at last by the work of which the first part is now under review

The realization, growing extremely rapidly during the last fifty years or more that the art of brewing has a strictly scientific basis has led a number of investigators in all parts of the world to inquire into the fundamentals and the details of the processes involved As in other fields of research, a marked acceleration in the output of original papers is to be observed since the close of the Great War and it has been the lament of many English readers interested in brewing that there are few, if any, books in the language which convey an adequate idea of the present position of brewing science and practice Nor do German text-books, for example, completely bridge the gap, since Continental practice differs in many respects from that in vogue in Great Britain

The present volume is concerned with materials, and, following an interesting historical introduction, is divided into six main sections devoted to barley, the biochemistry of malt and wort, malt, sugars, hops and brewing waters

The section on barley is extremely well done and serves to indicate the importance of the work of the geneticist in this field, and the valuable results accruing from a systematic study of the biochemistry of the raw material of the industry The work of Bishop in this connexion is well known in brewing circles, but even so it is of considerable value to have a succinct account of a number of papers which appeared originally in the *Journal of the Institute of Brewing*

From considerations of protein and carbohydrate composition of barley, and prediction of extract, we come to the next section, on the biochemistry of malt and wort This may be regarded as a somewhat extraordinary feat of compression, since in some seventy pages the author has discussed colloids, hydrogen ion concentration, carbohydrates, proteins and enzymes Clearly he has been in some difficulty here as he has had to cater for some technicians who may not be familiar with certain scientific conceptions of which others may be well aware When a second edition of the book is called for, it might be advisable to place this section first in order to pave the way to the section on barley and to preserve the continuity The sub section on carbohydrates might also be revised and slightly expanded for the sake of clarity

Following this digression, the main outline is again followed with a full account of malt, its constituents and analysis and the interpretation of the latter Analysis as an aid to the valuation of barley and determination of quality in malt has made large strides in recent years, but when the analyst has done his best (or worst, according to viewpoint) there still remain factors which in the judgment of many technicians may only be assessed in the light of experience.

In the case of sugars as in the next section the analyst is on safer ground since now he is dealing not with the complex products of plant growth but with much simpler substances obtained by more or less drastic treatment from the natural source

With the next section on the hop we return to the natural product and the treatment follows somewhat the same lines as in the case of barley Indeed there are parallels between the work on these two materials the nitrogenous constituents of barley have been the foremost objects of attack whilst those which determine the preservative value of hops have been most investigated Again the work of the geneticist on hops has produced results comparable in importance with those obtained for barley Thanks to this type of investigation hops of extremely high preservative value are now being produced and marketed

The concluding section deals at length with water supplies brewing waters the influence of salts and the general treatment of brewing liquors On the technical side the importance of the correct type of water for any particular process or product is not easily exaggerated on the more academic side the relations between the constituents of waters and the colloidal systems involved in malting and brewing provide a fascinating study for the physical and bio chemist alike

The book is well produced in large type on good paper references to many modern papers are given at the end of each chapter whilst author and subject indexes terminate the volume The author is to be congratulated on the successful issue of what must have constituted a difficult and laborious task We look forward with interest to the second volume on brewing processes

---

Advances in Biochemistry

Annual Review of Biochemistry
By James Murray Luck and Carl R Noller Vol 7
Pp ix+571 (Stanford University P O Calif
Annual Reviews Inc 1938) 5 dollars

THE Annual Review of Biochemistry appears for the seventh time a little late this year no doubt in spite of the efforts to ensure an early appearance three reviews previously announced have not materialized The academic success of the venture by which we mean the utility to workers in this ever widening field has led its sponsors to enlarge their activities by proposing to publish as a companion volume an Annual Review of Physiology which will be a joint undertaking with the American Physiological Society It will be possible to avoid duplication and make the two reviews mutually supplementary

The intensive culture of high yielding crops under conditions which render them very vulnerable to insect attack has brought to the fore the question of their protection and hence as a topic of timely nature the volume includes a review by F B La Forge and L N Markwood of the Bureau of Entomology Washington on organic insecticides of plant origin which includes the rotenone group pyrethrin quassin and nicotine There is considerable progress to report in the knowledge of the structure of these compounds the method of their application and their testing This review would have been of wider value if it had been more general in character

The enzyme section appropriately contributed by J H Northrop is now proudly headed Crystalline Three new enzymes—ficin protinase catalase and papain—have been isolated and crystallized last year the protein of reductase has been crystallized also the coenzyme of carboxylase The total of crystalline enzymes has now reached ten Even so the preparations may contain more than one protein

The carbohydrate section by E F Armstrong is devoted to the question of the structure of cellulose and starch materials which though so different in appearance as in behaviour are both entirely composed of glucose molecules Within the space available a readable account is given of this most difficult problem

The chapter on proteins by Max Bergmann and Carl Niemann rightly stresses the renewed interest in protein chemistry arising out of the question whether the biological activity of enzymes hormones viruses and toxins all of which are proteins is to be attributed to some unknown prosthetic group or to the intrinsic nature of the protein molecule itself It is recognized that the knowledge of the chemical molecule of the protein molecule is of primary importance far more so than physical chemical measurements made with impure materials

In reviewing progress in relation to hormones O Wintersteiner and P E Smith rightly select one or two sections for fuller treatment, namely the hormones of the adrenal cortex, testis and ovary Similarly the vitamins are divided into three articles the first by R A Peters and J R O'Brien is restricted to the B group the second by Peters and H W Davenport to the C group whilst a third by J C Drummond deals with the fat soluble vitamins In this way satisfactory stories of high interest are produced and this method of treatment should be insisted on by the editors in all sections

As showing the interest even in such a highly complex and special subject as the terpenes and saponins which are off the fashionable track of biochemical research it is stated that five hundred papers have been reviewed in chemical abstracts during the last four years This year s article is by W A Jacobs and R C Elderfield who strive to make clear the complex structure to the understanding of which they have contributed so much themselves

Sufficient has been said to show how adequately the reviews present the subject of biochemistry As it grows they form the only means of maintaining any kind of contact with it for many of us It is well therefore to urge upon the editors that they should err if necessary on the more general and descriptive side with an appeal to many, rather than be highly specialized for the few workers who in fact are of necessity forced to maintain touch with the literature as it appears week by week

Practical Organic Chemistry

Laboratory Manual of Organic Chemistry
By Prof B B Dey and Prof M V S Raman
Pp xii + 158 + xlv (Madras G Srinivasachari and Sons 1937) 7 rupees

IF one were to try to find any cause for adverse criticism of this excellent book it would be that it fails to suggest to the student the need for reading the original literature on the subject and fails to provide him with any help should he wish to impart some human interest into the dry details of experimental manipulation It is true that names are not entirely omitted but it is difficult to find any references by which the worker can be guided to the place where first hand details are to be found

Even now some teachers of chemistry do not recognize to the full the value both psychological and chemical attached to the human association of discoveries with their discoverers Surely there is nothing more fascinating than to read the story of the sugars as told by Fischer or the synthesis of nicotine as told by Pictet Something of the glow of accomplishment which must have been experienced by them still clings to the written description of it and imparts some of the thrill they felt to the reader Even in the elementary sections of the subject organic chemists can gain nothing but good by reading the original literature and to the advanced student it is absolutely essential

The book under review is divided into two parts Part I it is stated in the preface is intended to fulfil the requirements of the elementary student, while Part II should be suitable for the advanced students' A praiseworthy feature of Part I is the detailed description of many of the more important and more commonly recurring organic compounds whereby the student can make himself acquainted with the actualities of these substances It happens not infrequently that a student by failing to visualize the actual character of organic materials fails to appreciate the realities of the science Obviously the practical method is the best in all cases but sometimes this is difficult of accomplishment for lecture specimens are often nur Kochsalz und Wasser In this section the apparatus described is admirably and clearly reproduced One slight slip is noticed on p 27 where the failure to indicate that the safety tube passes to the bottom of the steam generator may cause trouble

The second part starts with some useful estimations which will be found of great service There follows a short description of the methods by which a mixture may be investigated This will be useful but it has to be remembered that the bad old days of spotting are past and the most that can be usefully achieved with an organic compound is to assign it to its class This point has been fully recognized by the authors although it would have been better had the results of the analysis on page 48 been stated thus The mixture was therefore composed of a phenol and a phenol carboxylic acid The former was shown to be β naphthol and the latter to be salicylic acid

The longest portion of this part is devoted to preparations There is nothing striking about this section but its inclusion is justified by the fact that any user of a handbook of this character must possess such information and it is well not to multiply the number of books required in laboratory work There is a useful appendix

The book is a good one and both authors and publishers are to be congratulated on its appearance It will be found entirely adequate by those who require a self contained laboratory manual on organic chemistry Nevertheless there are many such books differing from one another as the varieties of motor cars They are all made to go, and it seems to be the main duty of the reviewer to indicate that they will go' and to leave the user to choose for himself which particular variety suits him best

J F T

Asphalt Bitumen Pitch

Asphalts and Allied Substances
Their Occurrence Modes of Production Uses in the Arts and Methods of Testing By Herbert Abraham Fourth edition Pp xxiv + 1491 + 7 plates (London Chapman and Hall Ltd 1938) 60s net

THE use of bituminous materials can be traced back to very early times and the occurrence of natural asphalts had an undoubted influence on the course of civilization in Eastern countries A substance which could be softened or liquefied by heat and with which solid materials could be incorporated had obvious practical uses in addition to embalming and sculpture Perhaps the early civilizations of the Near East may be largely attributed to the possession of a constructional material which could be used as mortar in building for road making and on account of its water proofing qualities for the construction of boats and baths

The work under review first appeared in 1918 the second and third editions were issued in 1920 and 1929 (reprinted in 1932) respectively The author is both a practical man and also president of the Ruberoid Co and of Asphalt Shingle and Roofing Industry In the preface to the first edition it is stated that the author has taken it upon himself to draw freely from contemporary text books and journal articles adding that he has endeavoured to place credit where it belongs Inspection of the long bibliography and list of references suggests that the author has no cause to reproach himself in this respect

The work is divided into six parts of unequal length the same remark applies to the thirty seven chapters The first part contains a very interesting historical introduction and also gives a classification and terminology for bituminous substances The earliest use of asphalt is ascribed to the inhabitants of the Euphrates valley the remarks are illustrated by a map of the country from the Mediterranean to the Indus and by numerous photographs from recent excavations following the use of asphaltic materials through the centuries it is mentioned that the first mastic pavement made with Seyssel (Ain) asphalt was laid in Paris in 1835 and London followed in 1836 whilst rock asphalt from the Val de Travers was used for road making in Paris in 1858

With regard to terminology the author is careful in defining the way in which he uses such terms as bitumen mineral wax asphalt tar pitch etc this is the more necessary as terms are used occasionally with different meanings The materials dealt with are divided into four genera namely bitumens pyro bitumens pyrogenous distillates and pyrogenous residues The four genera are made up of ten species and the latter in turn of numerous members

In the second part of the book the occurrence and handling of native asphalts receives attention, needless to say considerable space is accorded to the Trinidad lake But although the author is an American he affords quite a lot of space to the deposits in the Old World illustrating his remarks with maps photographs of mining operations and numerous analyses

Tars result from (1) destructive distillation for example wood tar coal tar etc (2) partial combustion as in the case of producer gas and blast furnace tars or (3) cracking operations In Part 3 the author describes not only the more familiar tars but also devotes Chapter xix to fatty acid pitch and bone tar and pitch Considerable amounts of the former are obtained as by product of the soap and candle industries and from the refinement of vegetable oils and refuse greases Thus in refining cotton seed oil half a million barrels of foots are obtained annually in the United States from which the fatty acids are liberated and steam distilled Of the crude fatty acids treated thus ten to twenty per cent appears as cotton pitch Such fatty acid pitches find a ready use for cheap lacquers and japans and they may also be converted into infusible masses by treatment with sulphur or a phenol and formaldehyde Bone tar pitch is produced in comparatively small amount but is used by varnish makers to deepen the colour of japans

One large source of asphaltic material is afforded by the petroleum industry Petroleums may contain asphalt, and even when they are non asphaltic, asphalt may be formed during the distillation process An interesting sketch of the cracking and refining industries is given in Part 4, plant used being illustrated by clear line diagrams The discovery that petroleum asphalts may be converted into less fusible materials by partial oxidation has led to a large industry in blown petroleum asphalts

The manufactured products and their uses are dealt with in Part 5 (280 pp) A bituminous substance may be blended with other materials in order to modify its properties (fluidity, adhesiveness, tensile strength etc) and the compatibility of the added substance is of importance, this applies whether the added material is miscible or only a filler Other 'mechanical mixtures' are the aqueous dispersions which have acquired so much importance for road surfacing and which have many other uses Of the industries in which bituminous materials are employed special attention is paid to road making and roofing sheets and shingles (tiles) The thirty pages devoted to the latter includes directions for laying asphalt-shingle roofs, which some may consider outside the scope of the work

Part 6, on methods of testing occupies more than 400 pages and cannot be reviewed as it deserves in the space available The directions given are usually clear and each test has a number assigned to it Since the test number is given for each determination in most of the numerous recorded analyses doubt as to the method used in obtaining any particular result is eliminated

Paper printing and reproduction of illustrations (333) are good and despite the size, the volume is not unwieldy Spelling is American, to which the reviewer is accustomed and not averse Misprints are few those noted relating mostly to chemical formulæ and arising occasionally from misplacing or omission of brackets Thus Ca(OH) and ($CaOH_2$) occur on p 496, whilst on p 509 $CaOH_2$ as well as $FeOH_3$ and $AlOH_3$ are to be found

The book conveys the impression that the author found pleasure in writing it this in turn, reacts on the satisfaction of the reader

---

Statistical Interpretation of Experiment

Statistical Physics
By L Landau and E Lifshitz Translated from the Russian by D Shoenberg Pp viii + 234 (Oxford Clarendon Press, London Oxford University Press, 1938) 20s net

As a result of the many sided developments of the last twenty years the theoretical physicist has come to draw more and more upon statistical mechanics for the detailed interpretation of experimental results On opening a recent book with the comprehensive title Statistical Physics", one receives then at least a mild surprise to find that the subject is treated in an earlier manner, as a branch of mathematical physics divorced from any detailed connexion with experimental material The authors evidently decided to give a concise and lucid treatment of a definite field, and they have fulfilled their intention admirably Since in doing so they have kept within their chosen territory with an inflexibility that is unusual, it is desirable to mention the boundaries of this territory, without implying that these limits are unwelcome limitations

In their preface the authors state that their aim has been "to give a unified presentation of thermodynamics and classical statistics, based on the point of view associated with the name of Gibbs no attempt has been made at mathematical rigour in the treatment since this is anyhow illusory in theoretical physics, but we have instead tried to make clear the fundamental physical assumptions on which the results are based Having decided to confine their attention to classical methods the authors adopt the reasonable point of view that the reader scarcely needs to be reminded of the existence of the quantum theory When, for example, Dulong and Petit s law is derived, no indication is given that any progress has since been made in understanding the specific heat of solids , the subject is dismissed with the remark "At low temperatures and for all complicated solids, the law is obeyed very badly Even if one set out to write a book on statistical physics in which the electrical nature of matter was to be ignored throughout, and no known substances were to be mentioned by name, in these days care would be needed to prevent one's knowledge from slipping in unawares In this volume there are two or three passages where chemical substances are mentioned Apart from a passing reference to the size of the universe, only one experimental numerical value is mentioned, namely that of Boltzmann's constant.

In short the scope of the book is to present the mathematical theory giving a very readable exposition of the classical methods The authors have exerted themselves to convert the Gibbsian raw material into a palatable form To ensure that the underlying principles shall not be concealed by a notational undergrowth they have devoted the first two thirds of the book to assemblies containing only one species of particle They have provided more than fifty diagrams illustrating various aspects of the theory and scattered through the book are sixty examples—problems for each of which the method of solution is given these are a valuable feature

The later chapters include a section based on Onsager's treatment of irreversible processes and another section founded on Wagner and Schottky's theory of ordered solid solutions A chapter on anisotropic bodies is based on Landau's own work published in the Soviet journals R W G

Epistemology and Anti-Metaphysics

(1) Critical Realism

Studies in the Philosophy of Mind and Nature By Prof G Dawes Hicks Pp xxiv + 346 (London Macmillan and Co Ltd 1938) 15s net

(2) A Basis of Opinion

By Adrian Coates Pp xvii + 461 (London Macmillan and Co Ltd 1938) 16s net

PROF DAWES HICKS and Mr Adrian Coates agree in their decisive rejection of any form of subjective idealism and in their vigorous repudiation of an idealistic interpretation of physics They both expend much trouble upon criticizing various forms of sensum or sense data theories they are both concerned to deny that a sense datum is an object and they seek to draw important conclusions from this denial They diverge however so widely in their respective conceptions of and methods of approach to philosophical problems that even when they reach the same conclusions the grounds upon which their acceptance of these conclusions are based are entirely different

(1) The critical realism of Prof Hicks is critical in the Kantian sense of that word He agrees with Kant in putting in the forefront of philosophical inquiry the attempt to answer the question *how* knowledge of objects is possible His exposition of Kant's point of view is singularly clear and helpful He further agrees with Kant in holding that knowledge of objects involves both sensuous and conceptual apprehension But he discerns the weakness that led Kant to an unduly subjective view Prof Hicks directs his polemic mainly against the mistaken assumption that sense elements are discrete units that must somehow or other be synthesized into the object perceived He maintains that the sense datum is not an *entity* (*etwas*) upon which the act of perceiving is directed (*gerichtet*) The erroneous assumption that the sense datum is an object cognized is the cardinal error alike of Berkeley's subjective idealism and of those forms of contemporary realism that have been designed to avoid the difficulties of a representative theory of perception If we once admit that there is a *tertium quid* (sense datum or idea) between the cognizing mind and the world of real existence then we are driven to conclude either that the real object is unknowable or that the object known is a *construction* on the part of the mind itself a product of the mind's own making (p 5) I assume that a well known view of Bertrand Russell's would be a variant of the second alternative

Prof Hicks utterly rejects such views He replaces the notion of sense data or ideas as *objects* by the notion of *contents* There are three kinds of contents the content of the object the content apprehended and the content of the mental act Up to a point the distinction between these three kinds of content is made clear Unfortunately it is very difficult to know what exactly content is used to signify and why the same word should be used for the content of the object and the content of the mental act Content' seems here to be used as a synonym for a way in which the gap being filled in a way appropriate to the object apprehended and the mental act of apprehending it But a way in which stands as much in need of clarification as the word content that it is used to explain

I regret that lack of space prevents me from discussing Prof Hicks's theory in detail since it well repays study I must be satisfied with pointing out that he has provided good grounds for the view that colours sounds temperatures force energy strain, etc , are not mental constructs but are contained within Nature , that in perceiving we apprehend more or less accurately sense qualities which really are qualities of that which we perceive that is, of material objects finally that mind is not to be set over against Nature On all these points I should like to comment did space permit

(2) Mr. Coates shares with Prof. Hicks his impatience of the philosophizing men of science Unfortunately, he has not much tolerance of philosophers; he repudiates "as metaphysical nearly the whole course of philosophical speculation from the time of Thales to the present day" (p 27) "The root fallacy of the metaphysician", he says, "consists in applying the categories of science outside the sphere where they properly belong, and in reducing the whole of existence to the form of the subject-object relation" (p 29) Mr. Coates believes that the proper attitude of the philosopher should be that of the historian for whom the problem of appearance and reality, of subject and object, never arises in the form which this problem has taken in the philosophical tradition. The historian deals with persons knowing, acting, and feeling, one with another, he recognizes a plurality of persons in intersubjective intercourse

The working out of this point of view occupies the greater part of the book It is extremely well done Mr Coates is emphatic that a philosophy is a personal point of view. He is, however, more concerned to convert others than he is perhaps himself aware The method of conversion is to induce acceptance of a common language Perhaps Mr Coates unduly simplifies the problem At times he seems to suggest that if only you and I would agree to accept the commonsense usage of language as our norm, then our philosophical perplexities would be dispelled "People exist, things are real" (p 227) Accordingly, "existence is not subordinate to reality, but reality to existence"

How far does such a statement enlighten us? To know the answer to this question, it is necessary to read Mr Coates's book Whether one agrees or not with his point of view, it must be admitted that Mr Coates has written an interesting book and has much that is important to say with regard to the relation of language and logic

L Susan Stebbing

Indian Realism

Indian Realism

By Prof Jadunath Sinha Pp xvi + 287 (London Kegan Paul and Co, Ltd, 1938) 10*s.* 6*d* net

THIS is no simple exposition either of the doctrine of the Yogacara *Vijnanavada* or subjective idealism, or of the criticisms of the doctrine by the different schools and representatives of Indian realism The arrangement of the text is so confusing that although the book would probably be an excellent accompaniment for the student who is preparing to read the original texts for himself, it is emphatically not a work for the philosophically minded reader who wishes to be orientated in traditional Indian philosophical thought To begin with, the exposition is presented in a very complicated form. The co-ordination is faulty, there is no summarizing to help the reader, and it is difficult to disentangle the author's own comparisons with the views of European realists, where these occur. However, once the student has straightened out this confused presentation and has managed to ignore the unnecessary repetitions of Sanscrit terms, he will find that he has acquired a good deal of valuable knowledge on the subject

In the opening chapters, Madhavacarya's account of Yogacara subjective idealism is followed by a reconstruction of the doctrine from the works of such typical exponents as Santaraksita and Kamalasila, whose arguments against the existence of external objects have not apparently been given in any other works dealing with Yogacara idealism

The Yogacara arguments may, in general, be divided into two classes--epistemological and metaphysical The epistemological argument shows that cognitions are self-aware and cannot apprehend external objects, of which, again, the existence cannot be proved, and the metaphysical argument consists in showing that the nature of an external object cannot be ascertained Then in the following chapter, the arguments of the Sautrantika realists against the Yogacara doctrine of the non-existence of the external world is outlined by Madhavacara, while their own doctrine, which advocates a representationist theory of perception akin to that of Descartes and Locke, is expounded. This is followed by the counter-argument of Yogacara idealism against the Sautrantika representationist theory, which is set forth by Jayanta Bhatta, and an exposition by Sridhara of the Yogacara argument against the realist doctrines of the Sautrantika Further expositions and criticisms of Yogacara subjective idealism by the Jaina, Sankhya Yoga, Mimasaka and Nyaya-Vaisesika realists, take up the succeeding chapters Finally, the Vedanta critique of subjective idealism, in which the absolute idealism of Sankara is contrasted with the Yogacara subjective idealism, is set forth in the concluding chapter.

SHORT NOTICES

Agriculture

Mother Earth

being Letters on Soil addressed to Professor R G Stapledon By Prof Gilbert Wooding Robinson Pp viii+202 (London Thomas Murby and Co, 1937) 5s 6d net

THIS is an interesting and useful little book for the general reader Although couched in the form of letters the material apparently consists of the author s lectures to first year students of agricultural science omitting the more complicated diagrams and tabular matter but retaining the occasional shafts of professorial humour which relieve the tedium of yearly repetition—at any rate for the lecturer There are seventeen chapters or letters beginning with a discussion of soil material they pass to a description of soil profiles and surveys and their bearing on problems of soil fertility and the correct agricultural utilization of the various soil types

Leguminous Forage Plants

By Dr D H Robinson Pp vii+119 (London Edward Arnold and Co 1937) 6s net

THIS little book is not primarily designed for the expert, but rather to enable the inexperienced to identify the various legume crop plants that are grown in Great Britain and to explain their agricultural uses It accomplishes its purpose very well and is written in a clear and readable style The account of each legume commences with a description illustrated with excellent drawings This is followed by a short outline of the crop s agricultural uses A typical chemical analysis is given for most of the legumes described

The book contains a few inaccuracies which might be corrected in the next edition Thus it is not true to say that the nodule bacteria from red clover cannot infect white clover The variation in efficiency of different strains of nodule bacteria is an important and widespread characteristic and is by no means confined to the organisms that infect lucerne The discovery of such strain differences amongst the lucerne nodule bacteria is incorrectly credited to the reviewer The problem of clover sickness appears to be less simple than is suggested on p 18, and cannot always be attributed either to eel worm or *Sclerotinia* H G T

Theory and Practice in the use of Fertilizers

By Dr Firman E Bear (Wiley Agricultural Series) Second edition Pp ix+360 (New York John Wiley and Sons, Inc London Chapman and Hall, Ltd, 1938) 20s net

THIS well known text book, first printed in 1929, has now been brought up to date During the last nine years the subject has made great strides in its chemical, engineering and agronomic aspects, and within the limits of a single book, it is only possible to touch lightly on some of these The form of the book remains unaltered, but sections are added dealing with the inclusion of dolomite in fertilizer mixtures for use on acid soils, the use of granular fertilizers the addition of calcium sulphate to high analysis mixtures and the rapid methods of soil analysis for 'available nutrients' now being extensively used in the United States and elsewhere A new chapter has been added on the minor elements in soils and crops and examples of the necessity for the provision of traces of boron, copper, iron, magnesium, manganese and zinc are quoted mainly from American sources

Anthropology and Archæology

Other Men s Lives

a Study of Primitive Peoples By Sir George Dunbar Pp xiv+355+1 plate (London Ivor Nicholson and Watson Ltd 1938) 10s 6d net

THIS book is difficult to handle fairly It aims at giving an account of the mode of life of a primitive people as it develops from the stage of the simple hunter and food gatherer to that of the small farmer at the point of transition from the use of stone to that of metal The author describes the culture of the old and the new stone ages, and then passes on to give an account in considerable detail of the culture of the extinct Tasmanians and of the Indians of North America, who may be said to be, in a cultural sense, no less extinct The book is brought to a close with a description of the Abors, the little known, and for long inaccessible people living between the Assam valley and the Tibetan border land These people are taken as exemplifying in modern times a type of culture which has been shown to have existed in the stone age

Setting aside the question how far a modern so called primitive people presents an exact analogy with a prehistoric stone age people, from which it is separated by a gap of thousands of years, Sir George Dunbar s book appeals primarily to the non technical reader, since neither his account of the Tasmanians nor of the Indians of North America is other than a compilation At the same time, although he is not in the professional sense an archæologist, his account of the peoples of the stone ages interprets the material with the eye of an ethnographer with first hand acquaintance of how a people of simple culture really does live In the concluding section of the book, however, the author records the results of his experience during some years of residence among a people in a stage of transition from stone to metal. If on this account alone, his book deserves the attention of the scientific anthropologist

L'Art des Iles Marquises

Par Willowdean C Handy Pp 56+43 plates (Paris · Les Editions d'Art et d'Histoire, 1938) 75 francs

MRS HANDY, who in 1920–21 accompanied her husband, Dr Craighill Handy, on the Bayard Dominick expedition of the Bernice P Bishop Museum of Honolulu to the Marquesas, there devoted herself to the study of the tattooing for which the islanders have always been noted Her observation of this practice, highly important both in its ritual and in its decorative aspects, has afforded her an exceptional insight into the artistic activities and conceptions of the people, of which she here gives an admirable summary, while analysing the highly conventionalized designs into their component motives Of these motives the most important is the human form, a logical outcome of the idea, inherent in Marquesan thought, that to make anything is an act of creation, standing in definite evolutionary relation to the first act of procreation, by which Alea, the celestial father, fertilized One u i, the earth mother

In a brief comparative study, the author indicates her conclusions as to the relation of Marquesan art on one side to the archaic Maori art, with its divergent development owing to the technique of the chisel, and on the other to the art of ancient Peru, with which there are indications that there may be affinities

Canoes of Oceania

By A C Haddon and James Hornell Vol 2 The Canoes of Melanesia, Queensland and New Guinea (Bernice P Bishop Museum Special Publication 28) Pp vi+342 (Honolulu Bernice P Bishop Museum, 1937) n p

IN the second volume of this joint study of the canoes of Oceania by Dr A C Haddon and Mr James Hornell, the former has brought together and analysed an enormous mass of detail relating to the canoes of Melanesia and adjacent waters It is drawn in part from personal observation, in part from published, or in some instances unpublished, observations of travellers and ethnologists, sometimes going back to the earliest recorded visits to the islands by Europeans On the whole, this latter source is more satisfactory than the corresponding material under contribution in the preceding volume, which dealt with Polynesia

The problem, or rather series of problems, of the canoe in Melanesia, to which, as is well known, Dr Haddon has devoted many years of study, is infinitely more complex than that of Polynesia Not only is there the question of modifications possible through contact in trade, etc , but also this region has been subjected to racial and cultural drifts which have left their mark on the canoe perhaps as much as on any other element in culture This applies not only to general lines of construction but also to details, often, it might appear, of relatively little significance Thus, for example, in the Massim area of New Guinea, which is remarkable for the decorative carving of its canoes, Dr Haddon is able to discriminate between no fewer than four areas of difference, according to details of outrigger, sail, etc , while in the area of marginal communities in north-eastern Melanesia, south east of the Solomons (Tikopia, Rennel, Ontong, Java, etc), he shows how the canoes not only differ from those of their Melanesian neighbours, but also show traces of Polynesian and Micronesian influence, corresponding to differences in physique, language and culture

Biology

Genetics

an Introduction to the Study of Heredity By Prof Herbert Eugene Walter Fourth edition Pp xvii+412 (New York The Macmillan Co , 1938) 12*s* 6*d* net

IT is unfortunate that the fourth edition of this book should have been published in its present form The earlier editions provided an interesting account of the work of the early investigators and reflected the influence of this work on the current biological thought The present edition also contains much which is interesting from a historical point of view The author s lack of appreciation of modern genetics is shown, however by the description of crossing over in the two strand stage, the emphasis placed on Weismannism, the implication that the genes for sex are on the sex chromosome alone, and by the stress laid on the arbitrary division of genes into lethals, modifiers and other categories Much loose thinking vitiates the praiseworthy attempt to express genetical facts in popular language Eugenics not Bluegenics' , 'The cytological approach tries to find out what is the make up and behaviour of genes", 'Translocations and deficiencies are bound to cause embarrassment later when *synapsis* takes place, because some of the *genes* in the *mitotic* dance become wallflowers without a partner , are some examples of phrases which might have been expressed differently

F W S

The Way of Birds

By R B Talbot Kelly Pp 135 (London Wm Collins, Sons and Co Ltd , 1937) 25*s* net

THIS is a volume of large format, consisting mainly of coloured and other drawings—seventy two in all—with a few lines of text about each It is a book of birds as the artist sees them in life, and not of illustrations in which detail is carefully checked from museum specimens In a short introductory chapter, called 'Feathers , Captain Kelly expounds the difference "I used to think that herons were always blue grey in colour But I have seen a heron look blue, and pale ash grey, and purple grey, and golden buff in different lights at varying times of day The beauty of the feathered coat is that we perceive it as a whole , as a coherent, fluid vestment, not as a collection of separate feathers" On the other hand, "the scientifically accurate map-drawing of a bird's plumage pattern is a specialised form of art, or perhaps craftsmanship" A second chapter, called "Wings ', discusses form and movement—particularly in flight

The reader is thus prepared for generalized representations of colour patterns, and for unfamiliar shades seen in special lights. The test is severe, however, as the bird rendered static on paper becomes too readily comparable with the close-up appearance to which one is accustomed. So, while the method partly succeeds, the effect sometimes seems too strange to be credible. The difficulty is less with the black and white drawings which form the majority as one's attention is focused on the movement which the pose has caught. The result is often beautiful and life-like. Captain Kelly has clearly a real feeling for his subjects. His work is evocative of pleasant memories and stimulating to fresh observation.

Chromosomenbau

Von Prof. Lothar Geitler. (Protoplasma-Monographien, Band 14.) Pp. vii+190. (Berlin: Gebrüder Borntraeger, 1938.) 15 gold marks.

THIS competent and up-to-date monograph on the morphology and behaviour of chromosomes provides an outline of the structure of the chromosome in plants and animals, based on recent work. After describing the external morphology of the chromosome the author discusses euchromatin and heterochromatin, the formation of spirals, chromomeres, the salivary gland chromosomes of Diptera, and the physico-chemical nature of chromatin. A comprehensive bibliography is given while the illustrations are excellent.

This well-illustrated monograph can be highly recommended. F. W. S.

Chemistry

Laboratory Technique in Organic Chemistry

By Prof. Avery Adrian Morton. (International Chemical Series.) Pp. x+261. (New York and London: McGraw-Hill Book Co., Inc., 1938.) 15s.

THERE are so many books on this subject that the publication of still another makes the reader wonder whether it should be a welcomed addition to those already in print or whether it should be regarded as redundant.

The answer in this case is clearly the former, because the book is not quite like anything that has appeared hitherto. Few books provide guidance in both the inorganic and the organic laboratories, and if one is asked is it altogether desirable that this should be so, the answer must be that circumstances alone can determine the needs of the moment. Certain it is that if one were to possess and to use all the knowledge in this book, he might be regarded as almost one of the universalists, the days of whom are said to have ceased with Odling. The changes which have taken place during the last forty years are really amazing, for if the number of types of apparatus required for research purposes at the present moment are compared with those needed in 1900, it is clear that in those days the manipulator had to rely mainly on his own skill in order to form the kinds of appliance he required. Now the manufacturers reproduce in a very short time any special form of apparatus details of which may have been provided by an investigator, and it is ready for use at comparatively small cost, by anyone who may wish to adopt it for some purpose of his own. The American practice of using the names of describers to denote any variations in types of apparatus is used freely in this book. It is an open question whether this is desirable or not, but in Great Britain it is generally regarded as invidious, because the work leading to the elaboration of any special type is so often the outcome of team work. Nevertheless, perhaps in several instances cited in this book the inventor's name should be associated with his creation. It will suffice to mention two cases of the kind which stand out from the others, namely, the amazing apparatus of Doran on page 92 and that of Quiggle, Fenske and Tongberg on page 54.

The book is a good one and is to be highly commended to those who want a general treatise on modern chemical technique and all that that implies. J. F. T.

Grundzüge der Theorie ungesättigter und aromatischer Verbindungen

Von Prof. Dr. Erich Hückel. Pp. 160. (Berlin: Verlag Chemie, G.m.b.H., 1938.) 6 gold marks.

THE appearance of pamphlets such as the one under review indicates, if any indication were needed, the necessity for students of chemistry and particularly of organic chemistry, of possessing a working knowledge of German. The Germans write these short monographs so well, and the German publishers seem to like publishing them, although the profit must be small. In Great Britain there is a need for similar publications, but their sale is restricted by the fact that senior students (third year) rely nowadays almost entirely on their lecture notes.

The monographs, therefore, find their greatest use among the lecturers themselves and among the research workers who happen either to be personally interested or among those who wish to be kept fully up to date in the advance of organic chemistry. In these directions the monographs do great good, and in the present example the subject dealt with is one which may be said to be in the forefront of organic chemical discussions at the present time.

The saturated carbon atom, that is to say, one which has all its combining capacity satisfied or practically satisfied, is of less interest that the unsaturated atom in which such combining capacity is not satisfied. The discovery of Thomsen that the double bond in ethylene did not represent two single bonds gave an impetus to research in unsaturated carbon compounds which has led to fruitful work during the twentieth century. The cause of the striking differences shown by unsaturated compounds and those belonging to the 'aromatic' series is still the question of hypothesis and awaits the advent of an all pervading theory. It is this field of organic chemistry that has been chosen to supply the substances used by Nature for the purposes of animal and vegetable metabolism, and there can be no question that the problem of the chemistry of the life processes will be found to be based on them.

A knowledge of German provides, therefore, the student with the key to a door through which he can find much knowledge of the kind contained in this book. He would be wise to acquire it J. F. T.

Handbook of Chemistry

A Reference Volume for all requiring Ready Access to Chemical and Physical Data used in Laboratory Work and Manufacturing Compiled and edited by Dr Norbert Adolph Lange, assisted by Gordon M Forker With an Appendix of Mathematical Tables and Formulas by Prof Richard Stevens Burington Second edition, revised and enlarged Pp xvi + 1501 + 249 (Appendix) + 30 (Index) (Sandusky, Ohio: Handbook Publishers, Inc, 1937) 6 dollars

FIRST published in 1934 (see NATURE, **135**, 978; 1935), this extremely useful handbook has now proceeded to a second and enlarged edition, containing nearly 1,800 pages of valuable and easily accessible information Many of the tables have been revised while, in addition, there are sixteen new ones, the majority of which deal with the refractive indexes of solids and liquids Another useful addition, and one which will prove of considerable aid in the identification of organic compounds, is the listing of the melting points of such compounds in order of ascending values There has also been introduced a section on the numbering of ring systems

Of the parts which have been revised or rewritten, mention may be made of the sections on first-aid, the nomenclature of organic compounds and, particularly, of that dealing with the use of organic reagents in inorganic analysis.

This handbook is handsomely bound and is excellently printed, the matter being clearly set forth without any appearance of overcrowding, there is also a very complete index Altogether the book will prove serviceable to every chemist and be the means of saving much time which would otherwise be spent in a tedious search of the literature

Engineering

Electrical Measurements

By Frank A. Laws (Electrical Engineering Texts) Second edition. Pp. xiv + 739 (New York and London. McGraw-Hill Book Co., Inc, 1938) 36s.

COLLEAGUES of the late Prof F A Laws have seen the manuscript of the second edition of this text through the press, and have made sure that it contains the latest references and information which it is thought desirable to place before such undergraduate students as are looking forward to a career in electrical engineering. It is also intended to be of use to practising engineers who desire to understand the basis of testing technique which is found in practical work.

There is a great deal which the normal student does not need, and guidance from experienced teachers is therefore essential. There are also more extended references to the relevant literature than is usual; although it would be the teacher's delight if students could be induced to read original literature, it must be confessed that they would not be able to discriminate between various types of work and extract basic principles, for that is all that they have time for, from modern work, which is complex and possesses refinements obscuring the main idea

The newer high-voltage cable tests are included, but there is little that can appeal directly to the electrical engineering student who intends taking up high-frequency communication work The involved shielding of modern high-impedance precision bridges might have been made clearer, with larger scale diagrams

Radio-Frequency Electrical Measurements.

A Guide for Radio Engineering Laboratory Instruction By Prof Hugh A Brown Second edition Pp xvi + 384 (New York and London McGraw-Hill Book Co, Inc, 1938.) 24s

THIS text is intended to be the basis of a fourth-year radio engineering course for telecommunication engineers, and assumes a normal knowledge of electrical engineering and physics It consists of a large number of approaches to specified measurements, in the new edition exact procedures are outlined for the more difficult types of measurement. The cathode ray tube, with linear time-base, is freely used, and measurements of modulation and the frequency drifts of quartz-crystals, when used with valves as frequency controls, are included The standardized methods of ordinary measurements on circuit elements are numerous, and students would require a plan in order to make a useful selection

The course seems more balanced than others recently published, none of the experiments being trivial and none beyond a post-graduate student or a development engineer The art and technique of radio is advancing rapidly, but its advancement depends mainly on precise measurement The present text offers good training in this field.

L. E. C. H.

Geography and Travel

Gales, Ice and Men:

a Biography of the Steam Barkentine *Bear* By Frank Wead Pp xiv + 240 + 13 plates (London. Methuen and Co, Ltd, 1938) 12s 6d net.

"GALES, Ice and Men" is the history of what may be the last of the ice ships, the *Bear*, which had a long and honourable career from 1874, when she was built, to 1935, when she was laid up, perhaps finally. She was Newfoundland sealer, rescue ship (Greely, 1884), U S Revenue Service, with all that that entails in the far north Pacific, U S. Coast Guard and finally, at the age of about sixty years, one of the ships of the Byrd Antarctic Expedition. The *Bear* was built at Dundee and almost certainly in the same yard as the *Discovery*, although Scott writes of "Stevens's" and Mr. Wead of "Alexander Stephen & Sons' The two vessels are about the same size but the *Bear* was a little narrower and had not *Discovery's* stern the former showed perhaps rather better behaviour in dirty weather

It is almost impossible to believe that there is no more scientific work for a ship built to withstand the ice, and it is therefore the more important that there should be preserved records, as minute as possible, dealing with the construction and performance of such vessels If thirty three years ago Scott could write that ' it is all passing away , there is much more reason for apprehension now Mr Wead has written a sound book in a perfectly straightforward manner and is to be complimented on avoiding the dramatic It is rather a pity that in the brief outline of Alaskan history he omits the name of the indomitable Baranov J E H

The Scenery of England and Wales

By Prof A E Trueman Pp 351 (London Victor Gollancz, Ltd , 1938) 7s 6d net

IN his opening sentence, the author points out that 'In England and Wales we are singularly placed to appreciate the relationship of scenery and structure, for few other parts of the earth's surface show in a similar small area so great a diversity of rock types and of landscape features In this attractive little book, addressed to walkers and motorists as well as to students, an easily intelligible and pleasantly written attempt to stimulate that appreciation has been made

Although, as a geologist, Prof Trueman sees scenery from an anatomical point of view, as the external expression of internal structure, he does not omit to mention the softening influences of "waters blown by changing winds to laughter , or to exemplify the harmonious effects of native stone on the domestic architecture of the unspoilt countryside Each chapter deals with one area or type of country, such as the Cotswold Stone Belt the Pennine Moorlands, the Lake District, South Devon and Cornwall, and they are so arranged that the more complex regions come last

The work concludes with A Chronology of the Changing Scene and a brief survey of the geological history of the varied landscapes and seascapes that have culminated in our present day geography In a future edition the very short appendix on maps and books might advantageously be amplified

Geology

Landslides and Related Phenomena

a Study of Mass Movements of Soil and Rock By C F Stewart Sharpe Pp iv + 137 + 9 plates (New York Columbia University Press , London Oxford University Press, 1938) 15s net

IN this excellent and well illustrated book the author covers the whole field of his subject by treating the phenomena, not as isolated processes, but as stages in two continuous series, "in each of which there is every transition from moving masses of dry rock and soil at one extreme to masses of rock and soil abundantly impregnated with water or ice at the opposite end of the sequence" The movements themselves are distinguished as flow (continuous deformation) and slip (mass movement along a plane separating the moving mass from the stable ground), and each type is further subdivided in terms of rate of movement The classification thus arrived at is by far the best yet proposed, and has the great advantage of clearly relating the co operating processes and resulting forms to those of the recognized geomorphic cycles

Though brief, the book has a well selected bibliography and is thoroughly comprehensive Despite its high price, it is an indispensable work of reference that no geologist can afford to ignore

Geologisches Worterbuch, Erklarung der geologischen Fachausdrücke

fur Geologen, Paläontologen, Mineralogen, Bergingenieure, Geographen Bodenkundler, Studierende und alle Freunde der Geologie Von Dr Carl Chr Beringer Pp vii + 126 (Stuttgart Ferdinand Enke 1937) 5 60 gold marks

IN this German handbook of geological terms the definitions, descriptions and explanations are given briefly and in simple language Where it has seemed desirable, illustrations are provided, and certain terms, such as *erzlagerstatten*, *faltungsphase*, *formationskunde*, *orogenese*, *schichtung*, are amplified by means of schemes of classification In German speaking countries, the book will be a useful guide to the hard words and forbidding technicalities of a subject which is much more attractive than its German nomenclature In English speaking countries, students of geology, geography and related subjects will find the book invaluable, whether they are learning to read scientific German or, at a higher level of ambition, attempting to cope with the growing flood of German contributions to geological literature Clear explanations will here be found of many words for which hitherto they may have searched in vain

Mathematics

The Principles of Mathematics

By Bertrand Russell Second edition Pp xxxix + 534 (London George Allen and Unwin, Ltd , 1937) 18s net

MANY thinkers have regretted Bertrand Russell's desertion of the arid beauties of mathematical logic for the alluring dangers of practical ethics and sociology This new edition of the "Principles of Mathematics" will be welcomed by them not only because it makes accessible to all a book which fetched eight guineas when a stray copy could still be found, but also for its preface which many might wish to consider as a 'return to mathematical logic' This preface of ten pages shows, in fact, that Russell has never lost his interest in the subject He tells us that he sees no reason as yet to modify his views on his fundamental thesis of the identity of mathematics and logic, and he supports his opinions by a short discussion of the main contentions of the formalist and of the intuitionist schools.

An interesting admission concerns the status of logical constants, which 'must be treated as part of the language, not as part of what the language speaks about" (p. xi). In this way, Russell believes, logic becomes much more linguistic than he believed it at the time when he first wrote his book. Another reflection concerns the theory of types, which the author still defends in its purpose to establish a set of rules for deciding whether a given series of words is or is not significant. Summing up his estimate of the progress of mathematical logic, Russell is of opinion that the result is an outlook which is less Platonic, or less realist in the medieval sense of the word. "How far it is possible to go in the direction of nominations remains, to my mind, an unsolved question, but one which, whether completely insoluble or not, can only be adequately investigated by means of mathematical logic" (p. xiv). We might point out, however, that this opinion looks rather like an encouragement to his followers, if we take into account two facts: the tendency of logicians to reduce this symbolical apparatus to a minimum, and to return more and more to linguistic explanations of their views; and the tendency of 'logical' mathematicians and of 'mathematical' logicians to consider mathematics and logic as two separate disciplines in spite of their common elements. T. G.

Trigonometry

By Prof. T. M. MacRobert and William Arthur. Part 2: Higher Trigonometry. Pp. ix+203–341+xi–xiii. 4s. 6d. Part 3: Advanced Trigonometry. Pp. viii+343–478+ix–xi. 4s. 6d. Part 4: Spherical Trigonometry. Pp. vii+479–542+ix–x. 3s. (London: Methuen and Co., Ltd., 1937–1938.)

THESE books are companion volumes to Part 1, published earlier and dealing with that portion of the subject usually read by first year students in the universities and by pupils of advanced courses in schools.

Part 2 is designed to provide an introduction to analytic trigonometry and to the theory of logarithmic and exponential functions. The authors have given very lucid discussions on complex numbers, Demoivre's theorem, expansion in infinite series and hyperbolic functions. In the final chapters, the methods of the calculus have been freely used.

Part 3 deals mainly with convergence. There are three chapters, the first of which gives an elementary account of convergence; then follows a chapter on uniform convergence, whilst the final section is concerned with infinite products and with functions of a complex variable. Some interesting applications of the theory of Dirichlet's integrals to trigonometrical series are also included. An appendix is added in which there is a discussion of the length of a circular arc.

Part 4 is devoted entirely to spherical trigonometry and consists only of one chapter. Proofs of all the standard formulæ connected with spherical triangles are given, and the authors have suggested what appears to be quite a good scheme for the systematic solution of spherical triangles.

In each part numerous sets of exercises are provided at the ends of the chapters for the student's practice and, where necessary, answers are given. The four parts together form a thoroughly sound and comprehensive course in trigonometry which should be very useful to students of mathematics.

F. G. W. B.

Medical Studies

A Pocket Medical Dictionary

Compiled by Lois Oakes, assisted by Dr. Thos. B. Davie. Third edition. Pp. xx+397. (Edinburgh: E. and S. Livingstone, 1938.) 3*s*. net.

THE first edition of this useful and handy little work appeared in 1933. It has now been brought up to date by the inclusion of a large number of new words and 120 fresh illustrations. A considerable amount of heterogeneous information has been appended, such as notes on infant feeding, poisons and their antidotes, methods for working out doses, eminent medical men and gas warfare protection.

Climate and Acclimatization

Some Notes and Observations. *By Sir Aldo Castellani.* Second edition. Pp. x+198+4 plates. (London: John Bale, Sons and Curnow, Ltd., 1938.) 10*s*. net.

THIS excellent little book, which is based on the eminent author's prolonged experience of residence in various tropical climates, will prove of value not only to medical practitioners but also to missionaries, nurses and others who propose to take up work in the tropics. The work contains four chapters devoted respectively to introductory remarks on climate, to which the author attributes more importance than some of his immediate predecessors, such as Manson and Gorgas; the effects of climate on various systems of the body; a description of atmospheric pressure, trade winds, sun rays, chemical rays and moon rays; and acclimatization, including an account of the sanitary condition and health of white troops during various tropical wars, and particularly the Italo-Ethiopian War, in which the author was director general of the medical services. A classified international bibliography is appended.

Meteorology

Hurricanes

their Nature and History—particularly those of the West Indies and the Southern Coasts of the United States. By Ivan Ray Tannehill. Pp. x+257. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1938.) 16*s*. net.

THE early part of the book under notice gives a description of hurricanes, the tropical cyclones of the West Indies and the southern coasts of the United States, followed by a discussion of their tracks, the variations of pressure, the distribution of rainfall, the destructive effects of the high winds, and a full description of some historic hurricanes.

Nearly every aspect of the subject is treated, and well treated, and not the least interesting part of the book is the discussion of the relation of their origin to the presence of fronts It provides a much needed account of a subject on which general agreement has not yet been reached

Synoptic and Aeronautical Meteorology

By Dr H R Byers Pp ix+279 (New York and London McGraw Hill Book Co, Inc, 1937) 21s

DR BYERS discusses the subject of meteorology, and in particular the methods now known as air mass analysis from the point of view of the practical forecaster and succeeds in producing a picture of modern meteorology which is at once interesting to read and easy to follow Mathematical methods are avoided, as are the more speculative parts of the subject Special consideration is given to the forecasting of precipitation, fog thunderstorms tornadoes and other aspects of weather, the maps and charts being drawn from American sources This is a useful addition to the library of all who are interested in weather

Miscellany

Scientific Illustration

By John L Ridgway Pp xiv+173+23 plates (Stanford University, Calif Stanford University Press, London Oxford University Press, 1938) 18s net

THE object of this book is to aid students and others engaged in the preparation of manuscripts requiring illustration, which includes the method of assembly and display of illustrations and diagrams designed for scientific publications, and the placing of the matter in a form convenient for reference It ranges over almost every kind of illustration likely to be required by a scientific writer, including such varied subjects as geological specimens and sections, maps, photographs, processes of reproduction suitable for illustrations in colours and half tone, the construction of block drawings, and much else Useful hints are given on retouching specimen photographs and on the grouping of figures so as to make the most effective display

Naturally such a number and variety of subjects cannot be dealt with in much detail, but numerous references, mostly American, are given for fuller information

The author is scientific illustrator and artist, Californian Institute of Technology and Carnegie Institution of Washington, and was formerly chief illustrator, United States Geological Survey The book is very well got up and printed Every illustration and figure, of which there are many, is beautifully clear and well reproduced, in part due to the excellent paper used Judging by the plates and figures drawn by the author himself, he must be a most accomplished artist. We can recommend this work to all interested in illustration It contains many useful practical tips, evidently the result, as one might expect, of considerable experience in this class of work H L C

Business Man's Guide to Management

By G E Milward (Sixth annual edition) Pp. xiv+114 (London Management Library, 1938) 5s

THE sixth annual edition of the "Business Man's Guide to Management" covers all books published up to the end of 1937 In addition to the classified lists of books, with brief descriptive notes on their contents, a subject index, a publisher index, an author index and suggested courses for reading, a numerical and page index is now included Reference to the main divisions—general management, accounting, production, distribution, company secretary, psychology, industrial economics, public administration, and individual trades—is facilitated by use of distinctive paper for each of these divisions The more outstanding books published in 1937 are listed separately in the preface, this enhances the value of this cumulative guide to an important and voluminous section of literature

The Microscope Theory and Practice

By Conrad Beck Pp 264 (London R and J Beck, Ltd, 1938) 7s 6d net

THIS is a new edition combining Mr Conrad Beck's two previous books on the microscope, one elementary, the other more advanced, with the addition of much new matter, but, by judicious elimination, without increase in size The information given is clear and lucid, and can be understood by anyone having but an elementary knowledge of optics and mathematics The beginner will appreciate the directions given for the care of lenses and instrument, and for illumination and technique, the important subject of dark ground illumination being dealt with at some length Chapter iii, on apperture and resolution, gives full details on these important subjects, without a knowledge of which the microscopist cannot hope to obtain the best results, or correctly to interpret his observations Other chapters deal with the photometry of the microscope, microscope stands and accessory apparatus, micro-projection, lens testing and polarized light as applied to the microscope

The volume is profusely illustrated and can be recommended as a relatively simple and yet a comprehensive and trustworthy text book on the microscope and its use as an instrument of research

Philosophy

Einfuhrung in die mathematische Logik · und in die Methodologie der Mathematik

Von Alfred Tarski Pp x+166 (Wien und Berlin Julius Springer, 1937) 7 50 gold marks

THIS is a very useful introduction to mathematical logic, which does full justice to its title, in so far as it really carries the reader into the principles of mathematics interpreted mainly in terms of logical notions Most elementary works on this subject make a mountain of a molehill by confining themselves to the exposition of its purely logical prolegomena and dismissing their application to mathematics with the excuse that they are too difficult for lay readers Dr Tarski rightly thinks otherwise After a restricted account of the leading doctrines of symbolic logic (pp 1–97), he gives a short exposition of the idea of number, of the simple arithmetical operations, followed by a short discussion of the methodology and the axiom system of arithmetic This is an illuminating and sufficient introduction to the analysis of the logical foundations of elementary arithmetic But once the purpose and technique of the method are thoroughly understood, it will be easier for the reader to tackle the more advanced works on the subject Dr Tarski helps him in this connexion by suggesting a number of easy examples after each chapter Controversial questions are carefully avoided, and the technical apparatus is reduced to a minimum, though one may have wished for practice sake more symbolic formulæ and proofs Yet as it is, Dr Tarski s book, with the authority of its author, who is a leading member of the Polish school of mathematical logicians, fulfils a real want and is well worthy of an English translation T G

Explanation and Reality in the Philosophy of Émile Meyerson

By Prof Thomas R Kelly Pp xii + 134 (Princeton, N J Princeton University Press, London Oxford University Press, 1937) 9s net

THE epistemological doctrines of Meyerson have gained a permanent place in contemporary philosophy The influence of this eminent thinker radiates beyond the wide circle of his disciples, and explains the importance of authoritative expositions of his doctrines, such as the one written by Prof Kelly The dramatic conflict between the way followed by explanation and the way followed by reality is the source of Meyerson s system If he began by stressing these differences, however, Meyerson was led, later, to submit that some kind of convergence and identity of structure is necessary in order that the intent of knowledge may be achieved Prof Kelly follows closely the development of these doctrines, and while taking a sympathetic view of them, he does not fail to point out their outstanding deficiencies This work can serve as an introduction not only to the philosophy of Meyerson, but also to the central problems to scientific thought

Examination of McTaggart's Philosophy

By Prof C D Broad Vol 2, Part 1 Pp lxxv + 514 Vol 2, Part 2 Pp 515–796 (Cambridge At the University Press, 1938) 45s net

WITH the publication of these two parts of his "Examination ', the detailed exposition and criticism of "The Nature of Existence" is brought to its completion with that touch of brilliant scholarship which characterizes the works of Prof Broad The profound meaning of McTaggart s philosophy is thus brought to light in a much larger work it could scarcely be otherwise, if a thorough discussion of all the details of that great system was contemplated In comparing "The Nature of Existence" with the "Examination", one cannot help feeling as much admiration for the analytical and critical effort of the second as for the powerful synthetic composition of the first Here we can feel two minds grappling together with the major problems of thought and existence which have been the concern of the great thinkers of all times It is then a kind of anti climax to see Prof Broad write at the end of his inquiry, that he was struck by the thinness" of McTaggart s philosophy, and that he asked himself whether all this speculative effort was worth doing at all But perhaps it is in the very imperfection of all human attempts to solve the riddle of existence and yet in their ineluctable urge of trying to do so, that the eminent critic as well as any modest reader may find a cause for wonder at the achievements of the human intellect

Physics

Electricity and Magnetism for Degree Students

By Sydney G Starling Sixth edition Pp vii + 630 (London, New York and Toronto Longmans, Green and Co, Ltd, 1937) 12s 6d net

THIS well known text book has been extensively revised, and reset in larger type The changes which have been made include the insertion of an account of the Hall and allied effects and the omission of the description of the magnetization of ships The sections on atomic phenomena have been extended considerably and now provide a good introduction to this relatively new work The book, which covers rather more than is needed for a pass degree in physics and provides a sound framework for an honours course remains probably the best treatise of its kind in English on experimental electricity

Collisions of the Second Kind

Their Role in Physics and Chemistry By Dr E J B Willey Pp viii + 150 + 1 plate (London Edward Arnold and Co, 1937) 10s 6d net

THE molecular collisions most familiar to classical kinetic theory are those wherein the kinetic energy is conserved The early successes of the dynamical theory of gases are due to the fact that certain atoms and simple molecules do, in fact, resemble elastic spheres under a variety of conditions Latterly, however, an important group of phenomena has been discovered experimentally which shows that many gaseous collisions—particularly those involving electrons—occur with changes in the kinetic energy. The conditions which govern the conversion of kinetic energy into the various possible kinds of internal energy are as yet but dimly understood, and on that account alone, Dr E J B Willey s book is to be welcomed

The subjects covered are diverse, and include the excitation of spectra, inelastic collisions at interfaces, resonance radiation and chemical reactions

The book is the work of an enthusiast, who has himself contributed to the development of the subject Prof Frank is given fitting prominence throughout, and his portrait is included We feel certain that Dr Willey's work will be found helpful by a large number of research workers, to whom primarily it is addressed E A MOELWYN-HUGHES.

Infra-red and Raman Spectra of Crystalline Hydrochloric Acid

A KNOWLEDGE of the vibration rotation spectra of crystalline hydrochloric acid is of considerable importance in view of the theories of Pauling[1], Fowler[1], and others on rotation in the solid state Although several investigators have taken up this problem, the existing experimental data are confusing and even conflicting Thus Hettner[2] has reported that in infra red absorption a doublet band is found below the transition point (98° K) and a single absorption maximum above it On the other hand, Shearin[3] has reported the existence of thirteen discrete rotation lines at liquid air temperature (that is, around 85° K) and this result has recently been quoted[4] as indicating that rotation exists below the transition point It seemed possible that the discrepancy between those two results might be due to the fact that Shearin had the higher resolving power of a grating at his disposal We have just completed a very careful examination of the absorption near 3 7μ of thin layers of solid hydrochloric acid at the temperature of liquid air, using a grating spectrometer at least equal to that of Shearin s in resolving power

Our observations agree very closely with those of Hettner for this temperature We can find no trace of the individual lines in the positions indicated by Shearin, although there are signs of some further structure in the doublet In addition, we have examined the absorption of layers of solid DCl near 5μ at the same temperature Here we find not two peaks but three distinct maxima with indications of more structure The two extreme maxima appear to correspond to the maxima of the HCl doublet, since their frequencies give the same isotopic ratio As regards the appearance of the third maximum, we might remark that we have had indications of a similar additional peak in HCl when the gas has been condensed on to a surface at a temperature above that of liquid air and afterwards cooled to liquid air temperature The pure doublet is obtained when the hydrochloric acid is condensed immediately on a surface at liquid air temperature

VIBRATION SPECTRA OF CRYSTALLINE HYDROCHLORIC ACID

	Observers initials	Below transition point	At transition point	DCl
Infra red absorption	H	2708(s)2747(w)	2768	—
	L S & W	2704(s)2746(w)		1990(w) 1979(m) 1961(s)
Raman scattering	C & S		2763	
	L S & W	2709(s)2759(w)		

s = strong m = medium w = weak in intensity

The only observations on the Raman spectrum of solid hydrochloric acid are those of Callihan and Salant[5], who found a single broad line extending from 2,743 cm ^{1} to 2,784 cm $^{-1}$. The centre of this line is in good agreement with the centre of the single absorption peak found by Hettner above the transition point at 100° K Since the scattering experiments were done with the crystal only a few degrees below the melting point (presumably about 155° K) this seems quite satisfactory We have now succeeded in observing the Raman spectrum of hydrochloric acid at the temperature of liquid air. We find that it consists of two distinct lines, one of which, lying at 2,709 cm $^{-1}$, is much stronger and broader than the other at 2,759 cm ^{1} The uncertainty in the determination of the Raman frequencies is unlikely to be greater than 5 cm $^{-1}$, and of the infra red ones, 2 cm ^{1}, so there appears to be a small discrepancy between the value of the higher frequency according as it is observed in absorption or in scattering

A full account of these experiments, which are being continued at other temperatures and on methane and germane will appear later elsewhere

Predissociation Phenomena in Spectra of some Diatomic Molecules

IN emission at low pressure, the C band (0,0) of strontium hydride is cut off above $R(18) - 26{,}549$ cm $^{-1}$, the upper level of which (C, $v = 0$, J 19) lies 27,776 cm $^{-1}$ above the ground level N, $v = 0$ $J = 0$ In spite of this, Watson and co workers found no traces of the (1, 0) band in emission at low pressure, though the levels C, $v = 1$, J 1 to $J = 6$ lie only 27,620 to 27,770 cm $^{-1}$ above this ground level (cf More and Cornell[1], table 1) Thus the statement of More and Cornell (p 808) that the (1, 0) band lies far beyond the predissociation limit at $K' = 19$ in the (0, 0) band must be incorrect Consequently the predissociation occurs at an energy level at least $\sim$ 150 cm $^{-1}$ lower in C, $v = 1$ than in $v = 0$ Previously Herzberg[2] has found similar cases in the P_2 and N_2 molecules

Now it is very interesting that the C state of barium hydride behaves in quite an opposite way[3] Here in emission the (1, 1) band is clearly present, while only very faint traces can be recovered of the (0, 0) band Apparently we have to deal with two different cases of predissociation in the first case (P_2, N_2, CO, SrH) the cut off appears at lower energy and of course at lower J value, in a higher vibrational level than in a lower , in the second case (BaH), the cut off occurs at lower energy in a lower vibrational level than in a higher

According to Herzberg, the first case of predissociation here mentioned may be explained as an effect of potential barriers at large nuclear distances in the intersecting potential curve (Herzberg, case b) But if the crossing over" occurs above the predissociation limit (Herzberg case c), the transitions between the predissociated and intersecting potential curves take a greater role in the predissociation phenomena than in the first case mentioned According to the Frank Condon principle, the two cases of predissociation then may be explained as an effect of overlapping wave functions In $v = 0$ of the predissociated state, the wave function has one maximum between the turning points In the higher vibrational levels the maxima at the turning points are larger than those between the points Further, the difference $r_{\max} - r_{\min}$ between the turning points is larger at the same energy in a higher vibrational level with a lower J value, than in a lower vibrational level with higher J value If now the intersection takes place at the outer or inner part of the predissociated curve, then, as a result of both circumstances just mentioned, the $U(r) + T(r, J)$ curves belonging to low J values probably will be more influenced than those which belong to higher J values (first case) On the other hand, if the intersecting point lies near r_e and the intersecting curve is then mainly symmetrical between the inner and outer part of the predissociated curve, all the rotational levels in $v = 0$ may be more influenced by the intersecting curves than those of $v - 1$ (second case, BaH, cf Grundström, diss Fig 31)

Thus the position of the intersecting point in relation to the equilibrium distance r_e of the predissociated state seems to be significant for the predissociation phenomena

A fuller account will appear in the *Zeitschrift fur Physik*

Atomic Lines in the Auroral Spectrum

IN a letter in NATURE of June 25 R Bernard has published results of auroral spectrograms obtained at the Tromsö Observatory In that connexion, I should like to direct attention to the fact that all the experimental results he derives from his spectrograms are well known and have been described by me and my collaborators

The presence in the auroral spectrum of bands of the ε system, discovered and interpreted by me as due to the forbidden transition $A(^3\Sigma) - X(^1\Sigma)$ of N_2, was found in 1933[1] About fifteen vibrational bands of the ε system (now commonly called Vegard Kaplan bands) including those mentioned by Bernard were observed by me in the auroral spectrum[2]

It is also well known that spectra of diffuse auroras and auroras at great altitudes[2] in many ways differ from those of the distinct forms at low altitudes They differ, for example, in the appearance of a large number of weak lines, many of which are not to be found on spectrograms from distinct forms at low altitudes (cf ref 1, Pl 1 Fig 2)

The line 3470 was obtained by me with a large quartz spectrograph and measured so long ago as 1922[4,5], and on a large number of spectrograms during the following years

From our spectrograms of fairly large dispersion we get the mean wave length 3469 4 In accordance with the observations of Bernard, we find that the intensity of the line 3470 relative to bands of the $2P$ G may differ considerably for different spectrograms (cf ref 5, Table XI and ref 1, Table X) We have regarded the line as the head of a band $2P$ G (3–4) (3469), while Bernard has referred it to the line 3470 recently observed by Kaplan[6] in a nitrogen discharge tube, thought to be due to the forbidden transition from the metastable (^2P) state to the normal (^4S)-state of the neutral nitrogen atom

Our interpretation is supported by the close agreement in wave length and by the fact that a number of other bands of the series $2P$ G (3–n) appears in the auroral spectrum The great variation in intensity relative to other bands of the $2P$ G, however, would be accounted for if we suppose that an atomic line (3470) with varying intensity also appears Also on my spectrograms (cf plates, refs 1 and 2) the line appears sharp, but for small photographic densities the head of a band may also appear quite distinct

Although the present observational data do not settle the question as to the appearance of the NI line, the interpretation suggested by Bernard is of particular interest in relation to certain results obtained by me and my collaborators

Already from the spectrograms obtained in 1922–24 we measured a number of weak lines which were referred to atoms of oxygen and nitrogen in the neutral or ionized state Until recently, these lines had only been measured from spectrograms with small dispersion, so the identification was uncertain During the last two years, with E Tönsberg I obtained two of these lines (4415 1 and 4368 2) with a spectrograph of large dispersion and was able to identify them as O lines Their intensity follows the sunspot frequency, which shows that the concentration of oxygen atoms fluctuates in a similar way to the solar activity

Since these results were obtained, I have made a careful study in order to see which atomic lines might possibly appear in the auroral spectrum

Up to the present I have found that about twenty auroral lines may be referred to atoms of oxygen and nitrogen in the neutral or ionized state Within the limit of error ten of these lines coincide with nebular lines

In addition to the well known green and red OI lines, we find that the following forbidden lines from the atomic ground states may probably be present in the auroral luminescence The OII doublet $(^2D^0_2 - {}^4S_{1,2})$ (λ 3728 6), the OIII lines $(^1S_0 - {}^1D_2)$ (4362) and $(^1D_2 - {}^3P_2)$ (5003), the NII lines $(^1S_0 - {}^1D_2)$ (5751), $(^1D_2 - {}^3P_1)$ (6526) and $(^1D_2 - {}^3P_2)$ (6543) and finally, the NI line $(^2P_{1,2} - {}^4S^0_2)$ (3469 4) as suggested by Bernard

These results indicate that nitrogen and oxygen atoms in different states of ionization are present in the auroral region and that the physical conditions in this region are such that lines corresponding to forbidden transitions from the metastable ground states of OI OII OIII *and* NI *and* NII *appear in the auroral spectrum*

In addition, some auroral lines are observed which correspond to transitions from higher levels of OI, OII NI and NII

Bode's Law and the Systems of the Planets and Satellites

IN my letter in NATURE of February 5 (**141**, **245**), I pointed out that a slight alteration in the usual form in which Bode's Law is stated leads to some interesting results in Saturn's satellite system As the amended method of stating the law assists in certain conjectures regarding the satellites of Jupiter also, it may be desirable to repeat a few points in my previous letter If we take the distance of Mercury from each planet in turn (not the distance of the sun, as is usually done), it will be found that these distances are approximately in geometrical progression The figures are as follows

Mean distance between the orbits of	Astronomical units	Computed distance assuming the geometrical ratio 2 Astronomical units
Mercury and Venus	0 33	0 33
Earth	0 61	0 66
Mars	1 13	1 32
Asteroids	—	—
Jupiter	4 8	5 28
Saturn	9 21	10 56
Uranus	18 85	21 12
Neptune	29 74	42 24
Pluto	39 17	84 48

As is well known, Bode's Law breaks down in the case of Neptune and Pluto and the figures are not even approximate for these planets If the satellites of Saturn are dealt with in the same manner, taking the distance between Mimas and Enceladus as the unit, the actual and computed distances are as shown in the table below the geometrical ratio 2 being assumed

Mean distance between the orbits of	Astronomical units	Computed distance assuming the geometrical ratio 2
Mimas and Enceladus	1 00	1
Tethys	2 13	2
Dione	3 74	4
Rhea	6 69	8
Titan	20 29	16
Hyperion	25 37	32
Iapetus	66 07	64
Missing satellite		128
Phœbe	250 00	256

There appears to be a large discrepancy in the cases of Titan and Hyperion, but it was pointed out in my previous letter that, as these satellites have fairly large eccentricities, there may be certain difficulties in measuring their distances from their primaries with great accuracy It was also suggested that there is a missing satellite between Iapetus and Phœbe

The Jovian system presents certain interesting features which can be dealt with on the same basis—taking the distance from the nearest satellite, V, to satellite I, as the unit The results are as shown below, the ninth satellite being omitted for reasons which will appear later

Mean distance between the orbits of	Astronomical units	Computed distance assuming the geometrical ratio 2
V and I	1 00	1
II	2 03	2
„ III	3 69	4
IV	7 05	8
„ Missing satellite		16
VI	46 74	32
VII	47 93	64
VIII	96 71	128

There is a very definite gap between IV and VI and some months ago, while discussing the matter with my astronomical friends, I predicted that there was a missing satellite in this region It is possible that this prediction will be fulfilled if one of the two new satellites of Jupiter, recently discovered by Dr S B. Nicholson, is found to be between satellites IV and VI If its motion is direct, as it almost certainly would be in this region, I am of opinion that this completes the number of direct moving satellites of the Jovian system

The retrograde satellites have most probably had an origin different from that of the direct satellites If we consider the system of Uranus, it will be seen that the geometrical progression law is inapplicable, but there is a close approximation to the arithmetical progression rule Thus, if the distance between Ariel, the inner satellite, and Umbriel, the next in order of distance, be taken as the unit, the distances of Titania and Oberon from Ariel are approximately 3 and 5 units Presumably if another satellite of Uranus is ever discovered it will be 7 units from Ariel, or about 460,000 miles from its primary While this rule is purely empirical and only very approximate, it may, nevertheless be used as a criterion with regard to the retrograde satellites of Jupiter The distance between VIII and IX, the two retrograde satellites as known up to the present, is about 400,000 miles, and on the analogy of Uranus, the next retrograde satellite should be 800,000 miles from IX Hence, either satellites X or XI, newly discovered, should be at a mean distance from Jupiter of nearly 16 million miles How far the above figures will conform to those which will be computed when further observations have been made of the two new satellites remains to be seen If it is found that they both lie outside IX, there is still a missing satellite between IV and VI

Composition of the Earth at a Depth of 500–700 km

Price and Lahiri[1] announce interesting results of their study of the electrical conductivity, κ, of the earth from terrestrial magnetic variations They confirm the finding of Chapman and Price that there is a considerable increase in κ with increasing depth beyond 150 km below the earth's surface, and further, express the view that the really important increase in κ occurs at a depth of about 700 km , and they accordingly suggest a change in the composition of the earth in the vicinity of this depth This result is specially interesting in view of recent progress in other branches of geophysics, and the purpose of this note is to direct attention to the extent of agreement indicated

Seismological evidence has of course for some time made it clear that the major discontinuity within the earth occurs at the boundary of the dense central core, 2,900 km below the surface But more recently the work of Byerly[2], Jeffreys and Bullen[3] and Lehmann[4] on seismic waves has indicated a further change in elastic properties at a much smaller depth On the assumption of a sudden change, Jeffreys[5] placed the corresponding depth at 474 ± 20 km If the change is gradual, it may well be incomplete until a depth approaching 700 km is reached The corresponding main alteration in electrical conductivity might, on account of the existence of impurities in this case, not occur until the change was nearly complete This would agree very well with the result of Price and Lahiri , in any event it is significant that terrestrial magnetism and seismology both indicate changes at several hundred kilometres below the earth's surface

Another interesting point is that the value 700 km gives the limit of the focal depth of any recorded earthquake As pointed out by Gutenberg and Richter[6], 'this result is all the more striking in view of the fact that some of the deepest shocks are among the largest recorded"

Further evidence arises from a study of the density variation within the earth I have shown[7] that unless there is a change of material at a depth of the order of several hundred kilometres, the deduced moment of inertia of the central core would involve a most improbable distribution of matter Jeffreys[5] put forward the suggestion that the corresponding density jump found by me might be associated with a high pressure modification of olivine Bernal[8], arguing by analogy from known properties of magnesium germanate, pointed out that such a modification might take the form of a complete change in the crystal type of olivine to a cubic form The results of Price and Lahiri indicate a change in the value of χ from about 10^{15} to at least 10^{11} electromagnetic units It does not seem unreasonable to suppose that this figure may fit the postulated cubic form of olivine at the temperature and pressure reached

It appears thus that a number of distinct lines of evidence are in good accord in suggesting a change in properties at a depth of order 500–700 km below the earth s surface

Transparent Models to Illustrate Geological Structures

Large transparent models to show the structures of particular areas have been used for some years So far as I am aware they are less common in Britain than on the Continent, for example, at Lille, large models of this type have been made to show the structure of French coalfields These models have been built up by drawing numerous accurate sections to scale each on a separate glass sheet and arranging these vertically at proper intervals

Such models are invaluable to indicate underground structures to those not familiar with geological maps and sections and they are also helpful as a check on suggested interpretations of complicated areas Recently similar but smaller models of much simpler construction have been made As they appear to be useful in the teaching of elementary geology and are quite inexpensive a description may be useful to others Similar models may also be employed for demonstrating other structural relations

The model illustrated consists of a glass box, 6 in × 7 in × 3½ in, formed by four glass sheets fastened with Seccotine and fitted into slots in a wooden base Over the top is a sheet of 'Cellophane' fastened along the edges by 'Durofix' This upper sheet on which the geological map may be drawn, is cut by thirteen narrow slits, each vertically above a V shaped groove in the wooden base Thirteen sheets of celluloid with successive sections across the structure represented are thus kept vertically in their positions and can readily be taken out to demonstrate the section along any line Viewed from the side a model of this size is sufficiently transparent for the whole structure to be seen in three dimensions, about a dozen sheets of celluloid seems to be the maximum number which can suitably be employed but this depends on the amount of detail to be shown

Antiquity of the Modern Type of Man

Mr Marston s discovery of parts of a human skull deep in the gravel of the 100 ft terrace of the Lower Thames at Swanscombe is of great importance and significance Thanks to the careful and scientific manner in which this discovery was treated by him there can remain no doubt that these human bones were indeed *in situ* in the gravel and formed an integral part of it

The Swanscombe skull according to the expert anatomists who have studied it, would appear to be of the modern type, while on archæological and geological grounds, the specimen is to be referred to the Acheulean period Thus, it now seems established that as certain students of ancient humanity have held for many years the primitive Neanderthal Mousterian man was preceded in time by people closely akin in their bodily form to ourselves The discovery of the Swanscombe skull therefore once more opens up, and in a decisive manner, the question of the antiquity of the modern type of man Mr Marston s discovery is, however, not the only example of human bones of this general type claimed to have been found in Acheulean and earlier deposits But it has been the custom to regard it as necessary that any human bones claimed as of great antiquity must, in order to be accepted, and in addition to the geological data supporting this claim, exhibit definite primitive and simian characteristics

The reason for this would appear to be the belief that man is evolved from an anthropoid stock and, in consequence, any really ancient human bones would show evidence of this ancestry Various fossil remains of man do, of course, exhibit such characteristics, but there are others which do not, and the question arises as to whether *Homo sapiens* has evolved to his present state via the anthropoids Upon this important matter I am not entitled to express an opinion, but from my archæological researches, I am compelled to believe that intelligent beings—shall we call them—were in existence certainly a long way back in Pliocene time, and probably in that of the Upper Miocene

As things stand at present, however, I am confronted by the anatomists who tell me that no known anthropoid ape was sufficiently evolved at such epochs to make it possible for any flint flaking being to have been in existence, and the *impasse* is complete I have therefore read with great interest a remarkable article by Prof H H Woollard, F R S, in the current number of *Science Progress* In this article, Prof Woollard suggests that man arose from the primitive primate stem in very remote times, and long prior to the branching off of the anthropoids He states "If man has avoided many of the anthropoid specialisations it is logical to expect that he might retain many of the early primitive characters which the great apes have modified or lost" He then, having enumerated the various anatomical features which modern man possesses and shown that these are derived from the pre anthropoid primate stem, continues 'Those who have these characters could not be derived from those who have lost them A recrudescence of them by a subsequent mutation seems incredible

Now it seems to me that these are very formidable arguments, not lightly to be put aside, and I should much like to know what other anatomists have got to say about them If they are correct, then the great antiquity of the modern type of man and of intelligent beings capable of implement making becomes increasingly probable

Prof. Buckland and Oxford

The verses which follow are printed by permission of Sir Edmund Phipps, K C B, who found them among the papers of his great grandfather William Foskett of Bath (1763–1843), who was accustomed to preserve current songs, verses and anecdotes, communicated to him in various handwritings

William Buckland (1784–1856) was one of the founders of scientific geology He began to lecture at Oxford in 1813, and a special readership in geology was founded for him in 1819 He was elected fellow of the Royal Society in 1818, president of the Geological Society of London in 1824 and 1840, president of the British Association at Oxford in 1832, and Dean of Westminster in 1845 His best known work, "Reliquiae Diluvianae", was published in 1823; his Bridgewater Treatise on "Geology and Mineralogy" in 1836

Oxford

An Intended Epitaph on P[rofessor] Buckland at Oxford

Mourn, Ammonites, mourn, o'er his funeral urn,
Whose neck ye must grace no more
Gniss, Granite, and Slate, he settled your date
And his, ye must now deplore

Weep, caverns, weep, with filtering drip,
Your recesses he'll cease to explore,
For mineral veins and organic remains
No stratum again will he bore

Oh, his wit shone like chrystal ! his knowledge pro
From Granite and Gravel descended, [found
No trap could deceive him, no slip c^{d} confound
Nor specimen true or pretended —
He knew the birth place of each pebble so round
And how far its tour had extended —

Though eloquence roll'd, like the deluge retiring
In which many carcases floated,
To a subject obscure he gave charms so inspiring
Young and old on geology doted
He stood like an out lier his hearers admiring
In pencil each anecdote noted

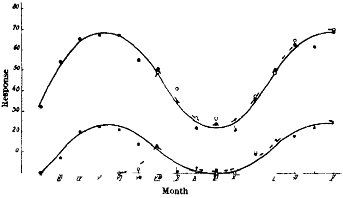
Where shall we our great Professor *inter*
That in peace may rest his bones ?
If we hew him a rocky sepulchre
He'll rise to break the stones
And examine each stratum that lies around,
For he s quite in his element under ground —

If with mattock and spade his body we lay
In the common alluvial soil
He ll start and snatch those tools away
Of his own geological toil
In a stratum so young the Professor disclaims
That imbedded sh^{d} lie his organic remains

Then exposed to the drip of some case hardening
His carcase let Stalactite cover, [spring
And to Oxford the petrified Sage let us bring
When he is incrusted all over
There with mammoths and crocodiles high on a shelf
Let him stand as a monument raised to *himself*

Annual Cycle of Responsivity of Castrated Albino Mice to Œstrone Injection

Laqueur, at the sixteenth International Congress of Physiologists held at Zurich in August last reported that the response given by capons to a given dose of androgen varies according to the time of year being lowest in winter and highest in summer An analogous rhythm in the responsivity of castrated albino mice to monthly injections of 1 I U of œstrone has been found to exist the response being more than three times as great in May as in November The upper full line curve in the accompanying figure represents the response given according to the State Hygiene Institute's method of evaluating vaginal smear tests in a group of 60 mice In this method (not yet published), points are awarded to each smear (cornified epithelial cells only 5, sporadic nucleated cells 4, cornified and nucleated cells in approximately equal number 3, sporadic cornified cells 2, nucleated cells only 1, and absence of epithelial cells 0 points), maximum response in a group of 20 mice is thus 100 points The lower curve represents the percentage of mice developing full oestrus after each injection A second group of mice was castrated in May 1937 and injections were commenced in June It will be seen (broken line curves) that the responsiveness attains that of the former group (castrated in January 1937) in August, and that the curves thereafter closely follow the earlier ones



Certain important conclusions may be drawn from our results First, it may be said that the results of work on the oestrogen content of biological material and based on vaginal smear methods not involving comparison with standard preparations, are highly inaccurate Secondly, the existence of an extraneous factor modifying responsivity to oestrogens is indicated Thirdly, should a similar rhythm exist in the human, the desirability arises of varying the dosage of oestrogens in replacement therapy, according to the season Finally, in animals exhibiting seasonal sexual activity, variations in this activity may be due not necessarily to increased hormone production, but also to increase in responsivity

Decarboxylation of Aspartic and Glutamic Acids

ACCORDING to our earlier reports[1], the legume bacteria split off quantitatively one of the carboxyl groups from *l* aspartic acid forming β alanine,

$$HO_2C\,CH_2\,CH(NH_2)\,CO_2H \rightarrow HO_2C\,CH_2\,CH_2NH_2 + CO_2$$

The reaction was at first accomplished only with living bacteria We have now succeeded in observing it also *in the presence of toluene* with the same bacteria The bacterial suspension, which had been kept 24 hours under toluene, split off carbon dioxide forming β alanine in an aspartic acid solution (pH 7) in the presence of toluene

In addition to aspartic acid, the legume bacteria split off the carboxyl group also from the *l* glutamic acid forming γ amino butyric acid,

$$HO_2C\,CH_2\,CH_2\,CH(NH_2)\,CO_2H \rightarrow HO_2C\,CH_2\,CH_2\,CH_2NH_2 + CO_2$$

This compound has been isolated as the gold salt The reaction is quantitative like that with aspartic acid The pH optimum is likewise the same (pH 7) The rate of the decomposition of glutamic acid is somewhat higher than that of aspartic acid Legume bacteria do not decarboxylate any other amino acids except aspartic and glutamic acids Thus it may be assumed that the same enzyme is acting in the decarboxylation of both these amino acids Since, however, Okunuki[2] has recently succeeded in decarboxylating glutamic acid with plant material, for example, dried beet powder, while aspartic acid does not react at all, it is likely that the legume bacteria contain two different amino acid decarboxylases, one decarboxylating glutamic acid (glutamic decarboxylase) and the other aspartic acid (aspartic decarboxylase)

As shown earlier by us[1,3], the coli bacteria split off the carboxyl group from lysine forming cadaverine almost quantitatively We suggest the name lysine decarboxylase for this enzyme

Segmental Interchange Lines in *Pisum sativum*

IN a former communication[1], a list was given of seven lines of *Pisum sativum* with different arrangements of their chromosome segments Four new types (structural types 8–11) have since been tested The chromosome relationships now recognized are summarized in the following table

			Chromosomes interchanged
Structural type	1	The normal or standard type (1 2 3 4 5 6, 7)	—
	2	Hammarlund's *K* lin	1 and 2
	3	The Thibet interchanged lin	1 and 3
	4	Extra Rapid	3 and 5
	5	An interchanged type from Miss de Winton's material	4 and 5
	6	An interchanged type from Prof Winge	1 and 4
	7	The doubly interchanged type from Structural type 2 × Str type 3	2 with 1 and 3
	8	*M*₁ a new type originating at Merton	3 and 4
	9	E Gt R, a new type originating at Merton in Early Giant Rogue stock	1 and 2
	10	The *G* line from Dr E Nilsson	6 and 7
	11	The *F* line from Dr E Nilsson	5 and 6

These interchanges have all been found in untreated material Each of the seven chromosomes has been found to be involved in one or more interchanges

The crosses structural type 1 × structural type 2, structural type 1 × structural type 9 and structural type 2 × structural type 9 all have a ring of four chromosomes at meiosis It is therefore clear that, although the chromosomes concerned in the two interchange types 2 and 9 are the same, a different combination of segments is involved Moreover, since neither of these lines has a dicentric (double attachment) chromosome, the break must have taken place on different sides of the centromere, in one and one only, of the chromosomes concerned in the two interchanges

Dosage and Response in Vitamin E Treatment

For the last two years in this laboratory we have been working to establish the relationship between dosage and response to vitamin E treatment Some discussion of the experimental conditions that we consider necessary for this work has already been published[1, 2] We have now completed a detailed account, which we hope to publish elsewhere, of the construction of a response curve, this is of the sigmoid type, owing to the quantal nature of the response in question

With the kind collaboration of Dr J O Irwin, it has been possible to calculate the equation to the regression line that relates the probits of the responses to the logarithm of the doses Between 200 and 250 animals were used in the construction of this curve, and the error of the mean fertility dose calculated from this curve was found to be, for $P - 0\ 99$, 71 141 per cent and for $P \quad 0\ 95$, 77–129 per cent Naturally, in individual tests where 10, or at most 20, animals are used, the error will be very much higher In one instance examined, where 10 animals formed the test group the limits of error were for $P \quad 0\ 99$, 48–209 per cent

In spite of the large inherent error, which appears to be unavoidable in this type of test, it is thought that the relationship established between dosage and response may be of use to others besides ourselves It makes possible calculation of the mean fertility dose of a source of vitamin E when the percentage fertility from a known dose has been established, the nearer the found fertility is to 50 per cent fertility the greater will be the accuracy of the value assigned to the mean fertility dose

We find that, if D_M and D_T are the mean fertility and the test doses respectively and if y_T is the probit of the percentage fertility found, then

$$\log D_M \quad \log D_T \quad 0\ 35y_T + 1\ 74$$

Points from Foregoing Letters

Further observations on the flow of liquid helium II are reported by Dr J F Allen and A D Misener showing that the velocity increases very rapidly between 2 177° and 1 15° K, and becomes independent of pressure as the area of the capillary is reduced In no case was a purely linear flow observed, and the correction due to surface flow was found to be small

Dr D H Menzel states that the usual assumption that an appreciable intensity of the forbidden spectrum lines only occurs at high electron density is not valid From mathematical considerations he deduces that the opposite is the case, and considers that the predominance of the forbidden lines in nebular spectra is attributable not to the effect of collisions in de exciting an atom before it has a chance to radiate, but to the weakness of the permitted lines

The absorption spectra at liquid air temperatures, of a thin layer of solid hydrochloric acid in the infra red region near 3 7μ and of the heavy variety, DCl, near 5μ, have been determined by E Lee, Dr G B B M Sutherland and C K Wu The authors find that the Raman spectrum of hydrochloric acid at the same temperature consists of two lines at 2,709 and 2,759 cm^{1}

The difference in the band spectrum of barium hydride, as compared with strontium hydride and other diatomic molecules, is discussed by Dr B Grundström, who points out that two different types of predissociation are involved

Following upon R Bernard s referring the auroral line 3470 to a forbidden transition of the neutral nitrogen atom, Prof L Vegard, after a further study of the auroral spectra, considers that a number of other lines may be due to nitrogen and oxygen atoms in different states of ionization in the auroral region

By applying to Jupiter s satellites the slightly modified Bode s law which was found to fit roughly in the case of those of Saturn J Miller infers that there is a missing satellite (after satellite No 4) and suggests that one of the two bodies recently discovered by Dr S B Nicholson may possibly fill that gap

Dr K E Bullen directs attention to the lines of evidence from different branches of geophysics, which all suggest that a change in the properties of the earth occurs at a depth of order 500–700 km below the surface

In view of the discovery of the Swanscombe skull, of Acheulean period but having characteristics of modern man, J Reid Moir inquires whether it is not justifiable to assume, as Prof Woollard does that man was derived from an earlier stock, prior to the branching off of the anthropoids

A seasonal rhythm in the response of castrated albino mice to injections of œstrone similar to that reported in the case of the action of androgen upon capons, is described by Dr J Duszyńska The response is greater in spring than in autumn, being more than three times as great in May as in November This variation affects the conclusions arrived at from biological assays by the vaginal smear methods unless carried out in comparison with standard preparations

A L Bacharach has studied the relationship of response to dosage of vitamin E An equation is given showing the relation between the response to an experimental dose and the dose that will give 50 per cent fertility in a group of animals

Research Items

Iron Age Poland

FOR four years, excavation has been proceeding on a six acre iron age village site at Biskupin in the northern part of Great Poland under the Poznan University Archæological Expedition This is a prehistoric stronghold which was built on a peninsula jutting into the lake of Biskupin on the surface of a former peat bog, in the Early Iron Age between 700 B C and 400 B C An account of the results is given by Prof J Kostrewski in *Antiquity* of September During the Bronze and Early Iron Ages a great part of Poland, as well as eastern Germany, was inhabited by an agricultural people known as the Urnfield people of Lusatian type, who are considered by nearly all Polish prehistorians to be ancient Slavonic Under pressure from a people probably of Baltic stock, they took refuge in forts of wood and earth in inaccessible spots, a number of which have been identified Nothing but the necessity of defence could have induced the inhabitants of Biskupin to occupy so unhealthy and unsuitable a site for building The peninsula, surrounded on three sides by the lake and cut off on the land side by marshy ground, was in addition strongly fortified by a wooden rampart filled with beaten earth carried round the whole site This rampart was built three times each time nearer the centre of the peninsula The rebuilding was evidently due to a rising in the water level The area was occupied by a populous settlement, composed of 80–100 huts, built on layers of birch fascines resting on the surface of the peat bog The ground plan was laid out in a masterly fashion, which would do credit to a modern town planner So far, eight perfectly parallel roads or lanes have been laid bare, in which rows of wooden huts stand side by side even touching The lanes are corduroy of oak logs The huts, about ten yards square, contain two rooms The floors are of beams covered with clay, and stone hearths were also covered with clay The antiquities recovered afford evidence of the continuity of Lusatian and later Slav culture

Artificial Incubation of Game Birds

THE demand for game birds in the United States has led to the development by private and commercial breeders of methods of producing game by incubator brooder methods Artificial incubation has given rise to many difficulties, and in an effort to solve these, Cornell University Agricultural Experiment Station has conducted, under the direction of Alexis L Romanoff, a series of experiments over a period of five years The results of the first two years work dealing with temperature and humidity requirements of pheasant and quail eggs were published some time ago, and now the results of the final three years appears from the Station as *Bull* 687 (March 1938) It concerns the effect of air movement and the role of the interrelation of temperature, air movement and humidity, in the incubation of pheasant and quail eggs Although each species has its own needs there is a definite relationship between these three factors, so that a proper adjustment of temperature and humidity must be made according to the rate of air movement Such adjustment permits the more extensive use of agitated air type incubators for greater efficiency in hatching Pheasants eggs incubated for the first 20 days in such an incubator may thereafter be hatched most successfully in a still air incubator under proper conditions But quail s eggs may be incubated and hatched most successfully in an agitated air incubator provided that with increase in air movement there is a corresponding increase in both temperature and relative humidity

An Indian Mosquito destroying Fish

THERE has been some doubt about the value of *Panchax panchax* as a mosquito destroyer, since F Sen found from an examination of the food under natural conditions that the fish showed no selective food habit It appeared to swallow any small moving object, animal or vegetable, which came within its range of vision , and the result was that only about 10 per cent of the fish examined contained mosquito larvæ Dr S L Hora and K K Nair point out however, that the waters in which the fish lives are as a rule free from mosquito larvæ, and therefore offer no assistance in deciding its mosquito control value They have therefore tested this value by two sets of experiments by introducing the fish into pits in which mosquito larvæ were living and observing their food from day to day, and by providing the fish with a mixed food supply in laboratory tanks and studying the food consumed, at intervals of 30 minutes (*Proc Nat Inst Sci India*, 4, 245 1938) In the first case, the observations showed that *Panchax* preferred mosquito larvæ, and only when they were absent or scarce did it turn to other insects, mostly ants Normally vegetation does not form any part of the regular diet In the second experiment, the fish also seemed to select the mosquito larvæ from amongst a miscellaneous diet But these experiments show the same fallacy as Sen's did , until we know the relative proportions of different sorts of food in the pools and tanks *before the experiment has begun*, we cannot decide from food eaten whether there has been selectivity or simply non selective swallowing of the food present

Boron Treatment of *Citrus*

DEFICIENCY of boron has been shown to be the cause of a widespread disease of *Citrus* trees in Southern Rhodesia The disease, known as hard fruit , is associated with spotting of the leaves, thick fruit rind, low juice content, absence of seeds, gumming and discoloration A A Morris (*J Pom and Hort Sci* , 16, 167 , 1938), analysing 21 random leaf samples, has shown that varying boron status is correlated with varying severity of 'hard fruit' incidence Applications of powdered borax to the soil at rates of 100–500 gm per tree resulted in rapid increases in the boron content of the leaves, and boron accumulated in the leaves with increasing age Leaves and fruit from 'hard fruit' trees were found to be low in boron With the possible exception of nitrogen, it was shown that the intake of the more common nutrient elements by the young citrus fruit does not appear to be influenced by boron treatment On the other hand, sugars and pectins were lower in boron deficient fruits than in fruits from trees under relatively low boron treatment High boron treatment, however, seems to retard rather than assist the translocation of sugars to the fruit A comparison of treated and control trees shows that severe losses of fruit are occasioned by deficiency of boron, not only during the growing season but also afterwards in the pack house In a particular area the number of fruits from treated trees was 10 411, whereas the controls yielded only 4 627 The disease, which occurs in areas where the soil is very shallow and subject to marked erosion, is now being controlled on a commercial scale by the application of borax

Gas Possibilities in New York State

THE discovery in 1930 of the Wayne Dundee gas field in Steuben, Yates and Schuyler Counties New York, and the more recent discovery of large quantities of gas in the Oriskany sandstone at Greenwood Steuben County, have awakened widespread interest in the search for other similarly favourable structures in the neighbourhood In 1934 and 1935, an allocation of funds was made by the United States Public Works Administration to enable a survey to be made, and since that date the United States Geological Survey has financed exploratory work W H Bradley organized the survey, and he has since, with the help of J F Pepper, recorded the results obtained in a detailed bulletin (*U S Geol Surv* 899 A) The area covered by the report includes more than 3,000 square miles of Steuben and Yates Counties south west New York, and parts of the six adjacent counties The main purpose of the survey was to determine the regional structure with the view of correlating it with sub surface structure How far this purpose was achieved is clearly revealed in the map showing areal distribution of key horizons and geological structure contours published with the report Ten domes which warranted test drilling have been mapped Moreover, during the course of construction of the map at least three potentially productive synclines were discovered It is, in fact possible from a study of this report to gain a clear indication of oil and gas possibilities throughout the area, and to supplement this by reference to the records of wells in the Oriskany sandstone and in the Wayne Dundee gas field included in the text

Energy Balance Sheet of the Gas Engine

UNDER this title a series of articles was contributed to *Engineering* by Dr F W Lanchester and these have now been reprinted in pamphlet form The author has preferred to use the term gas engine' rather than the more cumbersome internal combustion engine' for, whether the fuel be liquid or gaseous, the engine is a gas engine An especial value s attached to this very practical exposition of the author's method of accounting for the heat available and its disposition, as it represents the fruit of many years of study of the problems involved In discussing the debit side of the account, he claims that he lower calorific value of the fuel should be taken and also that a further initial deduction is due on account of the energy radiated by the flaming mixture to the cylinder walls As the engine is only capable of dealing with heat, this radiant energy, which never appears as heat and is shown to be about 7 per cent of the total heat of combustion, should be initially excluded Emphasis is laid on the advantages of conformal plotting on logarithmic paper By this method, when absolute pressure and volume are plotted, any expression of the form pv^{γ} = constant is represented by a straight line the slope of which is γ so that for example the diagram of the Carnot cycle for a perfect gas becomes a parallelogram easily plotted and readily interpreted Another simplification is introduced by expressing the relation of energy to temperature in terms of degrees of heat The basis of the analysis is that the heat apparent and the heat latent are separately accounted The former is the heat appearing in the indicator diagram, the latter is estimated from the difference deg H – deg T at the extreme peak of the diagram, and their sum is assumed, provisionally, to constitute the total heat supplied The jacket loss is reckoned as that taking place prior to the instant of exhaust release, and the exhaust energy is calculated as that existing at that instant Using deg H as a basis the energy balance sheet is drawn up the estimated jacket energy being divided between flame radiation and convection loss Referring to his method of dealing with inherent change of volume Dr Lanchester points out that when applied to engines using liquid fuel it properly points to an expansion and an increase of efficiency

Origin of Satellites

IN his paper entitled On the Origin of Binary Stars Dr R A Lyttleton considered the rotational instability of a single body, and showed that fission takes the form of the radial ejection of a portion of the mass, the two bodies having sufficient energy to escape from each other The principle is applied to a discussion of the satellites of the solar system (the origin of which has always been difficult to explain) in a recent paper (*Mon Not Roy Astro Soc*, 98, 8, June 1938) A brief mathematical investigation shows that the terrestrial planets and the satellites assuming the temperature of the material ejected by the sun to be about 10^6 10^7 degrees C, could not have condensed, as the material would have dissipated into space He conjectures that Jupiter and Saturn are the masses resulting from the catastrophic disruption of a single primitive planet, and as a filament of material would stream out between the components, the end portions would be captured and give rise to satellites The other portions of the material would be able to escape from both bodies and would give rise to the terrestrial planets When fission took place in the primitive planet, the layer of cleavage must have been as deep as the outer part of the heavy core of the planet and this affords an opportunity for the small planets to have a difference of composition and density from those possessed by larger planets The earth and moon came out of the catastrophe as separate bodies, and although our satellite may have been close to the earth, it never came within the Roche limit, for which reason the initial rotation period of the system could never have been less than 7 2 hours Dealing with Uranus and Neptune, Dr Lyttleton shows that if the fission which produced Jupiter and Saturn occurred at the distance of Uranus, escape from the system would occur The absence of companion planets to Uranus and Neptune is, therefore, explicable on account of their great distances from the sun, and, in addition, it is suggested that these two planets represent the more massive portions of their respective primaries.

International Federation for Documentation

Conference at Oxford and London

'Documenter c est reunir classer et distribuer des documents de tout genre dans tous les domaines de l'activité humaine"

THE fourteenth International Conference for Documentation, which has just been held at Lady Margaret Hall, Oxford, and the Science Museum, London, under the patronage of the British Government and the presidency of Sir William Bragg, has provided a demonstration of the increasing realization of the fundamental importance of documentation in intellectual and material progress The three hundred and fifty members of the Conference included delegates of thirty Governments and a hundred and fifty leading scientific and learned societies, research institutions, and international associations The growing interest in the work of the Federation was reflected in the aggregate of 106 papers communicated, an increase of 150 per cent on the number presented to the Jubilee Conference of the Federation at Copenhagen three years ago Above all, the spirit of international collaboration which inspires the Federation, made itself felt, not only in the study of the means of co operation in the task of making more fully available the records of human progress, but also in a remarkable feeling of international friendship and good will, which has pervaded the atmosphere of the Conference throughout its proceedings

The Conference has demonstrated, in no uncertain manner, the intense desire of thinking men and women all over the world to collaborate in the solution of international problems, including among them the co ordination of documentary work, as one of the most powerful means of promoting the happiness and material progress of mankind

As Lord Stanhope remarked, in proposing the toast of the International Federation for Documentation at the Government banquet, "that is not knowledge, which we do not know where to find" Buried in books, journals, monographs, reports, patent specifications and archives, to which continual additions are being made, lie masses of invaluable data and records of advances in every field of knowledge These facts lie hidden and inaccessible for want of a comprehensive index whereby to make them available as the basis of further progress In the absence of such an index, incalculable time, money and labour are being wasted every day in the repetition of investigations already completed To prevent this unnecessary delay, effort and expense is the object of the International Federation for Documentation, which seeks to unite all those engaged in the collection, classification and distribution of information, as well as everyone seriously concerned with the progress of knowledge, in the study and solution of this economic problem The importance of such work was pointed out by Sir William Bragg in his presidential address on "The Historical Papers of the Royal Institution"

The subjects discussed in papers by leading authorities from all countries might be said to cover almost the whole field of documentation The sessions were devoted to symposia on such subjects as the making of abstracts from periodical literature, applications of indexing systems, the practical application and use of bibliographies, the teaching of documentation, theories of cataloguing and classification, the organization of information services, and tools for library co operation

Two sessions, allotted to the discussion of photographic and other technical methods in their application to bibliographical problems, and apparatus for photographic reproduction of documents, were particularly valuable, as providing the most fully representative descriptions of the latest apparatus and authoritative opinion of all countries The exhibition arranged in the Science Museum, through the kindness of Colonel E F B Mackintosh, illustrating the most up to date apparatus, material and methods available for the purpose, is now open to the public and should certainly be visited

In accordance with a suggestion made at the World Congress on Documentation, held in Paris last year, that, in the past, the Federation had concentrated too exclusively on the scientific field, a special attempt was made at this Conference to include authoritative reports on the present state of bibliographical work in such fields of learning as archæology, archive work, economics, finance, history, law and painting This led to one of the most important sessions of the Conference Another session was devoted to a paper by Prof A F C Pollard, president of the British National Section of the Federation, on the mobilization of knowledge and the Permanent World Encyclopædia" of Mr H G Wells Assuming that the need for such an encyclopædia has been demonstrated conclusively, Prof Pollard gave an able survey of the reasons that have prevented the realization of this undertaking in the past, and indicated the mechanism by which these difficulties may surely and efficiently be overcome This is a paper the value of which is likely to be more greatly appreciated with lapse of time Mr H G Wells, who was present at this sitting, made a stimulating contribution to the discussion

The address of the president of the International Federation, Dr Alingh Prins, on problems of international documentation, was given during the week end, when the members of the Association of Special Libraries and Information Bureaux also were present for their annual conference and the full attendance was reached As a clear, comprehensive and concise synopsis of the problems involved, and the simple and completely effective methods available for their solution, this paper was certainly one of the most important contributions to the Conference Also during the joint sessions with ASLIB, Mr E Lancaster Jones read a useful paper on the evaluation of scientific and technical periodicals This included suggestions of methods utilizable by libraries in choosing periodicals to take.

From the above, it will be seen that the *Transactions* of the fourteenth Conference of the International Federation for Documentation contain perhaps the most comprehensive collection of original authoritative papers within its field, and should be studied by everyone who has at heart the mobilization of recorded information. The first issue has already been sold out. But, by the time these notes are in print, a new issue will be available at the moderate price of £1 net for the three volumes. These will be obtainable directly from the International Federation for Documentation, Willem Witzenplein 6, The Hague, or from its British National Section, British Society for International Bibliography, at the Science Library, Science Museum, South Kensington, S.W.7.

Those who are seriously interested in the task of making recorded information more fully available should put themselves in touch with Miss M. Gosset, the honorary secretary of the British Section at the above address.

Sir William Bragg's presidential address, as well as Dr. Alingh Prins' lecture as president of the Federation, together with the discussions of the papers will be printed in the *Communicationes* published quarterly by the Federation.

Space will not permit to describe the Government banquet in the beautiful Hall of Christchurch presided over by Lord Stanhope, the reception by the Vice-Chancellor in the Ashmolean Museum, the hospitality of the Mayor in the Town Hall, the garden party given by Dr. and Mrs. Priestley at their beautiful manor house at March Baldon, the interesting visit to Messrs. Morris Motors Ltd., the tea provided by Messrs. Kodak Ltd., and the various other visits and excursions which did so much to create the prevailing atmosphere of friendship and provided those opportunities of social contact that constituted such a valuable part of the proceedings of the Conference.

S. C. BRADFORD

Association of Special Libraries and Information Bureaux

Annual Conference

THE fifteenth annual conference of the Association of Special Libraries and Information Bureaux, held at Lady Margaret Hall, Oxford, on September 23–26, was somewhat overshadowed by the anxiety of the political situation, and also by the Conference of the International Federation for Documentation, which held its fourteenth annual conference simultaneously. If the joint sessions with the latter Federation unfortunately suffered from the depressing effect of an excessive number of papers which characterized the sessions of the International Federation, the remaining meetings at the ASLIB Conference had their characteristic spontaneity, and the discussion on the work of the Association at the annual meeting in particular indicated a lively interest on the part of members in its continued progress.

The president-elect, Sir William Beveridge, was unfortunately prevented by illness from giving his address on "The Use of Books in Social Science". Mr. E. W. Wignall's paper on "Museums and Research: Some Facilities in London", gave an indication of the extent to which museum officers carry out research, not only for their own departments but also for Government departments, universities and scientific institutions of different kinds all over the world. Facilities for workers not on the staff of a museum are often limited by the space available or the demands made on the time of the museum staff, and Mr. Wignall urged that in any new museum it is of the utmost importance that adequate study rooms should be provided. He also stressed the question of acknowledgment, very considerable help being sometimes given to a student which receives no acknowledgment in his subsequent papers. A brief subject list of museums in London was included in the paper.

At the annual general meeting of the Association, the honorary treasurer, Mr. A. F. Ridley, submitted accounts showing a slight balance of income over expenditure as compared with the deficit of the previous year. Although the membership of the Association has also increased from 308 to 325, the report of the Council once more emphasizes the necessity for a much larger membership if the Association is to fulfil the functions which belong to it. The report also refers to the increased circulation of the ASLIB Book List and to the issue in May of a second edition of the Select List of Standard British Scientific and Technical Books. Increasing use is being made of the inquiry bureau and the panel of expert translators has been reorganized, a new register having been established under new regulations. Eighty-six members have now been enrolled under the modified scheme.

In the absence of Sir William Beveridge, Mr. B. M. Headicar presided over the evening session on September 24, when Mr. Frederick Brown, lecturer in statistics at the London School of Economics, read a paper on "The Compilation of Statistics by Trade Associations", in which his felicity and liveliness of exposition drew the warm appreciation of a large audience. Mr. Brown referred to the difficulty of generalizing about the statistics compiled or issued by trade associations owing to the wide variations in practice both in compilation and in objective or use. Terminology is also important, as frequently trade statistics cannot be interpreted without knowledge of special terms used or of the way in which they are compiled. Among the services which trade associations can render to their members in this way is the reproduction of market prices of special interest to them in the calculation of special index numbers.

While most trade associations base their statistical work on data collected and compiled outside, some few associations are breaking fresh ground, and Mr. Brown emphasized the opportunities which await trade associations in the field of statistical research, in such matters as the compilation of figures of consumption and production by members, stocks and plant capacity and operating or production costs. In this connexion Mr. Brown pointed out that if such work is to have any value, membership of the association must be representative of the trade or industry as a whole, or comprise such a majority of the trade that firms who are not members are too insignificant to affect the returns

Such statistical research could take two main forms that of the descriptive study as seen in the survey of milk consumption in England and Wales undertaken by the Milk Board or of the investigation type as in the survey of nutrition effects of milk also undertaken by the Milk Board , or the investigation into the causes of the marked fluctuations in retail trade about Easter and Whitsuntide undertaken by the retail distributors associations Mr Brown pleaded for greater participation in such research by the universities and for greater readiness to place statistical information at the disposal of the community for the advancement of knowledge He referred to examples of co operation in this respect between the Retail Distributors Association the Bank of England and the London School of Economics, which while securing a check on possibilities of error and safeguarding the disclosure of individual sources of information, has made the collective returns accessible for research or public purposes

At the final session on Sunday evening Mr Max Nicholson, secretary of Political and Economic Planning (PEP), gave an interesting account of how material for the PEP Press Report was compiled, which is of some interest to scientific workers as an example of the possibilities of the group method of inquiry and research into subjects in which very little published information is available, and especially in making available neglected experience and buried sources of information Mr Nicholson also stressed the value of PEP anonymity

---

Society of Chemical Industry

Autumn Meeting

THE autumn meeting of the Society of Chemical Industry held in Glasgow on September 16–20 was notable for a symposium of papers on the trend of progress The opening paper presented for the Food Group by Dr L H Lampitt, referred to the part played by chemists in the effort of nations to secure self sufficiency and particularly to the issues involved in the storage and preservation of food Dr Lampitt asserted that although internationalism in the scientific world is less pronounced we are heading towards international agreement in certain aspects of dietetics as well as towards increased Government control of the efforts of chemists in the field of food science

On behalf of the Road and Buildings Materials Group two papers were presented In the first of these, Mr R Fitzmaurice discussed the question how far standardization and how far freedom of design are to predominate in the building industry Referring to the accumulation of the scientific knowledge necessary to replace tradition, Mr Fitzmaurice indicated some of the possibilities which standardization offers, given close co operation between the architect and engineer as in the 'Mapin' system of instruction He referred also to the question of building regulations and the obstacles they sometimes present to progress whether in the introduction of new materials or new methods Mr Fitzmaurice referred also to the large number of British standard specifications now in existence for building materials Many of these should provide a valuable safeguard for the purchaser in respect of particular properties of materials which constitute a source of difficulty in practice, but many architects appear to be unaware of their existence This position, however, may slowly change through the use of these specifications in official specifications for Government or local authorities works

The second paper, by Mr J O Willis, dealing with road design, urged a trunk road policy in the construction of which full advantage could be taken of modern practice of alignment, and all interruption of the main streams of traffic obviated by overbridges and properly laid out junctions He stressed the importance of standards of riding quality and the improvement of surface quality particularly of the need for the introduction of new methods of laying bituminous roads Resistance to skidding is of vital importance, and Mr Willis considers that asphalt surfacings finished with precoated chippings, are only a palliative The ideal he suggested is a fine textured bituminous carpet impervious to water and presenting a uniform texture throughout its life In the light of work in Great Britain and in Holland rubber might play an important part in solving the problem

The paper presented by Dr V E Yarsley on behalf of the Plastics Group referred to the fact that, in the plastics industry, only rarely has one material dominated another This position is likely to continue, although with the balance of power inclining in favour of the thermoplastics group The current trend is towards improved tensile properties and greater stability to heat, making possible the use of higher temperatures and the production of larger moulded units In the field of cellulose plastics, the development of quick growing celluloses which can be produced within Great Britain or the Empire is an obvious gain in a national emergency Cellulose triacetate is now a commercial possibility, and ethyl cellulose is promising for coating and impregnating compositions The attention now being devoted to the production of shock resisting phenolic plastics should ultimately provide an entirely new field for exploitation, while extended phenols should also do much to emphasize the possibilities of plastics as "the fourth material of construction" Amino plastics are also promising for transparent plastics, and other possibilities lie in laminated plastics and for creaseless fabrics The increased use of plastics for the production of high-duty wheels, gears and bearings, and also for airscrews, struts and construction parts in aircraft is only one of the developments to be expected

In the final paper of the symposium, Prof W M Cumming and Mr F Rumford reviewed tendencies in chemical engineering both in regard to materials and to unit operations In regard to the former they referred to the development of new alloys but stressed the importance of scientific comparison and selection They referred also to the use of special steels for high temperature and high pressure reactions in view of the importance of creep at elevated temperatures as well as to the efforts being made to replace nickel at least in part by other metals in a number of special cast irons, and to the attention devoted to the technique of welding and the interest in organic materials such as rubber Similarly, the authors briefly reviewed developments in heat transfer, filtration, size reduction, distillation, including the use of a true counter current system throughout the column, evaporation, drying, dust removal and other unit operations while in conclusion the question of education was discussed and the importance of avoiding uniformity of training was stressed

Appropriately enough, a paper by Dr R Gilmour at a joint meeting with the Institution of Chemical Engineers on "Chemical Engineering in the Fermentation and Distilling Industries" had much to say about the place of art and science in the distillation of whisky, including the effect of air, water, malt and peat on the production of a high class whisky

Diffraction and Refraction of Radio Waves

THE increasing application to various radio purposes of ultra short electric waves of less than 10 m in wave length has given a new stimulus to the problem of calculating the field strength at distances from the transmitter such that the ionosphere is of negligible influence The solution of the problem of the diffraction of electric waves around the earth was first given on a sound basis by G N Watson in 1918, but this analysis involved assumptions which, while perfectly valid for the long and medium waves then in use for radio communication, are not justifiable for the ultra short waves now being considered For example, at long wave lengths, the conductivity of the earth may be assumed to be infinitely great for analytical purposes, but as the wave-length is reduced through and below 10 m, the actual value of the conductivity and also the dielectric constant of the soil over which the waves are propagated has an important influence on the field strength at a distance from the source Furthermore, the height of the receiver above the earth's surface may no longer be assumed to be a negligibly small fraction of a wave length, when the latter is only a metre or two

In a recent paper published by T L Eckersley and G Millington (*Phil Trans Roy Soc*, A, **237**, 273–309; 1938), a phase integral method has been applied to the problem of obtaining a formula for calculating the electric field at a distance from a wireless transmitter This method agrees with Watson's theory in the case already considered by him, but it has the advantage that it more readily permits of extension to the case of finite earth conductivity and of an elevated transmitter and receiver The authors claim that the phase integral method has a certain generality in exhibiting the solution as one of a general class appropriate to problems of this kind, this feature encourages the hope that other problems of the type may be solved by similar methods The application of this analysis to the wave propagation problem has also afforded a solution to the case not considered in the original problem, but of considerable practical importance, where there is a gradient of refractive index in the atmosphere above the earth

The paper to which reference is made above presents the detailed analysis involved in this work in a form which exhibits clearly the physical nature of the problem Formulæ are derived from which the field strength may be obtained for any wave length, distance from the transmitter and conductivity of the ground over which the waves travel Furthermore, the increase of field as the receiving post is raised above the earth's surface is obtained, and by using the reciprocal theorem, the analysis applies as well to the case when the receiver is on the ground and the transmitter is elevated By combining both cases the effect of having both the transmitter and receiver can be calculated

A very satisfactory feature of this investigation, which will be much appreciated by those engaged in practical radio communication, is that the various formulæ have already been reduced to the computation of numerical values A paper by T L Eckersley (*J Inst Elec Eng*, **80**, 286–304, 1937) gave a complete set of field strength/distance curves for wave lengths between 2 and 10 m and for conductivities corresponding to land and sea Other curves provide the relationship between field strength and height, while a simple means of extending the curves to take account of refraction through the atmosphere is explained for application when the vertical gradient of refractive index of the air is known or can be estimated While these theoretical results await adequate experimental confirmation, they are already of considerable value as a general guide to the radio engineer, and in this case the graphs referred to above were utilized by the recent International Telecommunications Conference in Cairo in considering a preliminary allocation of bands of ultra short waves to various classes of radio communication

University Events

GLASGOW —On September 29, the Gardiner Institute in Medicine, attached to the Western Infirmary, Glasgow, was opened by Lady Gardiner The Institute is under the direction of the regius professor of medicine in the University, and will be devoted to clinical research At the opening ceremony, Prof T R Elliott delivered an address in which he stressed the great advantage to be derived from the establishment of such an institute, and emphasized the necessity of a closer co operation between the science and practice of medicine

The following appointments have recently been made in the University Dr O Löwenstein to be lecturer in zoology in succession to Dr H B Cott, newly appointed lecturer in vertebrate zoology, Cambridge, Mr Vernon D van Someren to be temporary assistant in zoology in succession to Dr Margaret W Jepps, who has been awarded a Leverhulme fellowship for one year

Science News a Century Ago

The Zoological Society

AT a meeting of the Zoological Society on October 9, 1838 Richard Owen began the reading of a paper on the osteology of the Marsupialia He remarked upon the great value of an acquaintance with the structure of the skeleton in determining the genera and species of this group of animals and proposed a new genus *Thylacomys*, for certain species presenting a peculiar conformation of the cranium In treating the maxillary bones, Owen said that he was induced to enter more largely into details, from the great interest attached to the fossil jaw found in the oolitic strata at Stonesfield and the doubts which had lately been expressed by M de Blainville as to its true mammiferous character The author had examined four specimens of which one was in the museum at York, another was in the collection of Mr Broderip and the other two were in the possession of Dr Buckland The double fangs to the molar teeth, and the ramus of the jaw being formed of a single bone he thought sufficiently attested the mammiferous nature of these remains , while minor anatomical characters led him to regard them as belonging to a marsupial genus

Meteorological Science in Germany

WRITING from Carlsruhe a correspondent of the *Athenæum* said The attention of scientific men is just now directed to a curious discovery of Professor Stiefel—well known throughout Germany for his researches in Natural Science—the result of which has been the attainment of a more accurate knowledge of those changes to which the atmosphere is subjected than was possible by the old methods The instruments hitherto in use have been the thermometer and the barometer, but an unerring standard has been considered a desideratum that is said to have been at last supplied in the shape of geranium fruit, the awns of which are *in* and *e*volved by the dryness or humidity of the atmosphere in obedience to laws so regular and unvarying, that being fixed upon a dial plate properly graduated, the change from one part of a room to another may be noted with the greatest accuracy A paper on the subject was to be read at the meeting of German naturalists, held this year at Freyburg Professor Stiefel is the greatest weather doctor in southern Germany, and has for many years tabulated all changes in the atmosphere, according to a plan suggested by Goethe, but he does not venture to predict for more than twenty four hours at a time and laughs at our weather prophets (*Athenæum*, Oct 13, 1838)

New Botanic Gardens in Regent's Park

"THE interior portion of the Regent's park, ' said the *Mechanic's Magazine* of October 13, 1838, 'will shortly be laid out as botanical gardens, the Commissioner of Woods and Forests having granted a lease to a society newly formed under the title of the Royal Botanic Society of London, at the head of which is the Duke of Richmond as president The object of this society is the formation of an extensive botanic garden, with a library, museum, and conservatories, so that medical and scientific as well as merely ornamental botany will respectively receive the attention commensurate with their importance '

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Monday, October 10

University College London at 5—Dr Phyllis Tookey Kerridge The Physiology of Hearing and Speech (succeeding lectures on October 17 24 and 31) *

Warburg Institute (at the Royal Society Burlington House W 1) at 5 30 Prof V Gordon Childe India and the West before Darius *

Royal Veterinary College London at 5 30 Prof T W M Cameron Principles of Parasite Control (succeeding lectures on October 11 and 13) *

Tuesday October 11

Royal Society of Medicine (Section of Therapeutics and Pharmacology) at 5—Sir Frederick Banting F R S The Immunity Aspect of the Tumour Problem (W E Dixon Memorial Lecture)

Institution of Electronics (at King s College Strand London W C 2) at 7 30 Dr J A Darbyshire Applications of X Ray Diffraction and Electron Diffraction Methods to Industrial Research *

Thursday October 13

Institute of Fuel (at the Institution of Mechanical Engineers Storey s Gate London S W 1) at 2 30 Lieut Colonel J H M Greenly Presidential Address At 3 Prof R W Wheeler Destructive Distillation (Melchett Lecture)

University College London at 5—Dr R J Lythgoe The Physiology of Vision (succeeding lectures on October 18 20 25 and 27) *

Friday October 14

School Nature Study Union (in the Conference Hall County Hall Westminster Bridge London) at 6—Autumn Meeting

Sommerville Hastings The Plants of Rocks and Mountains *

North East Coast Institution of Engineers and Shipbuilders at 6 Annual General Meeting

Major T Russell Cairns Presidential Address

Cinematograph Films Modern Steelcraft

Appointments Vacant

Applications are invited for the following appointments on or before the dates mentioned

Junior Scientific Officers at the Ditton Laboratory Maidstone and the Low Temperature Research Station Cambridge—The Establishment Officer, D S I R 16 Old Queen Street Westminster S W 1 (Quote ref J 38/12 October 12)

Chemists and **Assistant Chemists** (grades II and III) under the War Department Chemist Woolwich—The Under Secretary of State (C 5), War Office Whitehall London S W 1 (Quote appts /101 October 22)

Head of the Junior Technical School of the Royal Technical College Salford—The Director of Education Education Office Salford 3

Science and National Service

IT was apparent during the recent critical weeks that, though the problem of the utilization of science in war-time had been under consideration, no comprehensive scheme for this purpose was in existence The immediate danger is now past, but there are clear signs that the peace obtained by consultation is not of a character which will permit of any relaxation of military preparations The problem thus still remains an urgent one, though we may hope for the time to work out a reasonable rather than improvised scheme If this is to be done in a way that is not likely to waste the capacities of scientific workers, or to damage the structure of scientific knowledge and research, scientific men will need to take the matter in hand

In the first place, it must be emphasized that no scheme for the utilization of science can be satisfactory to citizens and men of science unless its ultimate aim—the utilization of science for human welfare in times of peace—is kept steadily in view The idea which appears to be prevalent in certain countries, that the main activity of human communities is the waging of war and that peace is merely an armistice for future war preparations, is not one which is compatible with the maintenance of civilization or of science Consequently, the organization of scientific workers for war must be conceived in such a way that the minimum damage is done to the possible beneficial utilization of science. This involves the safeguarding of fundamental scientific research and of the main lines of its application, so that once the danger of war is definitely removed, science can advance as rapidly as possible in carrying out its true purpose. It involves, further, the protection of the life and efficiency of a sufficient number of key scientific workers, and the maintenance of a continuity of scientific teaching and training It would be found that such provision would not, in fact, be detrimental from the strictly military point of view, and that the effective utilization of science for war purposes requires, to be fully effective, a proper balance between civil and military uses for science, even in war-time

If we are to face in a realistic way the possibility of war, certain steps should be taken immediately in the organization and the use of science, while others of more drastic character will be needed only if and when war breaks out Scientific war preparations in peace-time involve two types of activity The first is the organization and development of basic and applied scientific research in such a way that it may be of value for war without losing its actual or potential peace-time value The second is the training of a certain number of scientific men, and the preparation of many more, for possible war-time activities

It is clear that measures that were adequate for the Great War are unlikely to prove so in a future war waged under conditions which will probably be even more severe and prolonged. Preparation for such a war requires not only a much more thorough organization of science, but also a much closer integration between scientific research and the other activities of the community, particularly those of industrial production, agriculture and health

When we review the potential needs of the British Isles, or the British Commonwealth, in war-time, we see that they are primarily those of maintaining a human community at full effectiveness under conditions of shortage of supplies, shortage of men and of general disorganization due to enemy attack Most of these are simply the problems of normal civilized life raised to a much higher degree of urgency consequently development of scientific research to cope with these problems is bound to follow in the main the same lines as those required for the proper utilization of science in peace

The five principal needs of a modern community under war conditions are (1) maintenance of the military and civil populations (2) maintenance of war production (3) defence against aerial attack (4) the carrying on of military naval and air operations (5) care of casualties Each of these problems makes special demands on certain of the sciences and requires peace time development of research on certain specific points The strain of war conditions is not uniformly felt it bears particularly hard on certain sectors in which there are deficiencies not perceptible in peace time These weak points are those most likely to break and the breaking of any one of them may entail military defeat or what is more likely under modern conditions economic collapse

It is impossible to itemize all these weak places but there are at least six which are of cardinal importance food non ferrous metals rubber motor fuel optical instruments and medical supplies For all of these we are dependent to a large degree on imports which may be restricted or cut off altogether At the same time they are all products in which an application of science can provide either alternative sources or effective substitutes If this is to be done however it is not only necessary to provide as at present for applied research in these fields fundamental research is just as necessary provided it is well linked with practice In the case of food for example the work of geneticists plant physiologists biochemists and nutrition experts is no less important than that of agriculturists

Similar considerations apply to the more purely military aspects of war The defence of the civil population against aerial attack has created entirely new problems Protection against the effects of high explosives will necessitate a combination of evacuation and construction of shelters which will involve research in population distribution and in building

The carrying on of military operations is itself a large scale industrial undertaking The question of fuel may be a crucial one Already a great deal of fundamental and applied research has been done on the problem of artificial fuels but it is still open to doubt whether a more direct attack on the problem free from the confusion of rival interests might not yield more economical production of motor fuel from coal than at present obtains Another characteristic of modern warfare is the dependence it places on scientific means of detection and communication An adequate supply of optical instruments of the highest precision is needed and this requires a development of the optical industry and of optical research on a scale that has not yet been attempted

With the new weapons of destruction which have been developed since the last war and particularly with the bombing of cities casualties are likely to be heavy and serious The medical profession will have to face a heavier task than in any previous war It is difficult to improve technique in dealing with casualties under war conditions and therefore special efforts in medical research are required in order to prepare new and improved methods of treatment and rehabilitation Much greater quantities of medical supplies will be required particularly of drugs for there is reason to believe that the home production is inadequate even for peace time We need at once to develop drug production and research on drugs comparable to that already existing in Germany and on a far larger scale than the £30 000 provided by the Medical Research Council for chemotherapy allows

These are some of the more obvious needs that war would bring for applied and fundamental science There are many others which will be apparent to those working in different fields But if these needs at least are not dealt with now by provision and adequate facilities for research on both laboratory and factory scale the effect of this neglect in war time will be disastrous Further it will be necessary to secure that men trained in the different scientific techniques are reserved for scientific service in war time and that the best use is made of the registers now being compiled by the universities possibly through the collaboration of the learned societies

The problems which war raises for scientific research are however not independent and demands made for one or another of them would in the absence of co ordination merely increase the existing confusion and inefficiency of research If science is to be used to some extent for the protection of humanity in war it needs to be organized more comprehensively than it is at present This is not to criticize the existing organization of science but to point out that it requires to be extended and more closely knit We need a National Research Council covering the whole of science and relating it to the running of the community both in peace and in war The French Government has just set up such a council which is linked with all the defence Ministries as well as with that of national education This is not the place to discuss precisely how such a council should be formed or how it would group existing organizations but certain requirements must be satisfied if it is to succeed in its main purpose of utilizing science for national service In the first place it will need to command the active loyalty of a great majority of the scientific workers in Great Britain They will best collaborate with a body which they feel represents the most effective scientific workers and not simply those chosen on a basis of seniority or official position Further at any rate the younger among them will not work wholeheartedly if at all to organize science for a possible war unless they see evidence that the intention of political policy in general is to prevent war Lastly if the war should come their attitude towards it will largely depend on whether it is a war for or against the principles of democracy and civilization

There are two ways in which the scientific man can be used under war conditions One is by putting him in the position of a military subordinate whose business is to obey orders and not to think The other is to give him a chance to use his imagination and knowledge co ordinated with that of his fellow scientific workers and technicians to criticize and direct in so far as he is competent the character of operations In the first way it is impossible to get the best out of scientific men even if they are willing to comply with the conditions Any adequate organization of science cannot relinquish the fundamental scientific right of criticism Stifling of criticism led to great losses in 1914–18 it might have an even more disastrous result in a future war The full utilization of scientific workers requires the use of their ingenuity far more than of their routine service and this can only be secured by giving them opportunities and liberty of initiative The degree to which this is done may be a decisive factor and its neglect might mean defeat in which the prospects of reconstruction afterwards would be irretrievably damaged It is for the citizens and scientific men in the democratic States to see that this does not happen on their side

Foundations of Human Inequality

The Origin of the Inequality of the Social Classes

By Prof Gunnar Landtman Pp xvi + 444 (London Kegan Paul and Co Ltd 1938) 21*s* net

PROF LANDTMAN S book in spite of certain shortcomings will obtain a permanent place in anthropological literature as an encyclopædia of fact and theory on such subjects as the earliest differentiation of society according to age sex and personality the role of wealth manual skill and commercial efficiency in creating primitive stratification the question of early phases of priesthood in its dogmatic social and ritual aspects The chapters on slavery are valuable as a summary of older work supplemented by recent evidence The book deals somewhat briefly in the last two divisions with the genesis of nobility and with the origins of government

Inspired though it is by the classical tradition of British anthropology the book lacks the charm and the intuitive genius of Frazer it falls short of the standard set by Westermarck in his almost uncanny creative acumen in the analysis of fact and its relevance it has not the flashes of inspiration characteristic of the work of Crawley At the same time the sincerity the thoroughness and the complete impartiality in dealing with facts and theories will allow the reader to draw his own conclusions from the material conscientiously and skilfully accumulated by the author

The very quality of the book and its high standard of scholarship invite criticism on one or two points In his treatment of the origins of government for example the author fails in my opinion to recognize some of the relevant aspects of the problem It is of course necessary to discuss whether in certain primitive communities power is vested in a council or a monarch in a male chief or a queen mother handed down by a hierarchy or distributed through a confederacy Another important question however still remains In what way do the rulers of primitive peoples carry out their work ? And indeed in what does this work consist ? Do they ever take any legislative initiative or is custom regarded as unalterable ? In what way are their administrative functions carried out—through specific executive organs, a tribal police, the chief's henchmen, or by magic and sorcery ? An analysis of primitive government might have considered such aspects as legislation, jurisdiction and administration, as well as its fiscal, magical and military functions

This substantial side of the problem is scarcely touched upon Prof Landtman gives us almost exclusively the structure, or the form, of early government The question of its scope and functions is interesting for here we have apparently considerable differences according to area In Melanesia, where I studied it at first hand, the actual sphere of activity of chiefs, councillors and officials is very limited They do not act as rulers, but rather as political masters of ceremonies The actual rule is exercised by custom The chief acts as mouthpiece of the traditional routine in war and in economic activities , in the interpretation of legal rules and their application In Africa, on the other hand, the initiative and executive power of the rulers is apparently much wider and more substantial In a comparative study like the present one, it would have been of great value if the author had revealed the common measure as well as the variations in the actual work of early government The problem is not merely theoretically important, but also has actual practical relevancy under systems of indirect rule, and, indeed, in all cases where colonial policies are being framed or overhauled

Again, the practice of starting with a definition instead of letting it grow out of the material collected, might be questioned Thus when, after a very useful review of older theories and definitions of slavery, the author tells us that slaves are "an unfree class which, occupying the lowest rank in human communities, are more or less entirely subject to the power of their masters" (p 229), it seems that from the substance of his subsequent analysis a much better definition could have been framed For it might have been given not only in the somewhat general terms quoted, but also in summing up the main characteristics of slave labour , of the position of slaves in their freedom to marry and reproduce in terms of legal status and political disabilities

As a follower of Rousseau, Prof Landtman endorses A R Wallace's opinion that "among people in a very low state of civilization, we find some approach to such a perfect social state" *Perfect* here seems synonymous with *equality, homogeneity, lack of oppression* and *plenty of food and simple commodities* For Prof Landtman tells us that "Not only the non-existence of social ranks but certain other features of the life of undeveloped native tribes undoubtedly suggest attributes of the utopian social state of philosophy Such is the high moral standard of some of these tribes and, above all, such the seemingly happy and untroubled life some of them lead surrounded by a luxurious tropical nature No wonder that they have acquired the admiration of so many enthusiastic travellers" (p 4) As a corrective to the constantly reiterated statements describing the primitive as "fear ridden", "witch haunted", "paralysed by anxiety neurosis", or "living in debauchery and sexual promiscuity", such a view is a welcome exaggeration of the opposite aspect of primitive life

As a matter of balanced fact, however, the stone age man of to-day fits neither into the pages of Rousseau nor into those of Hobbes He is neither primarily happy nor panic-ridden , neither virtuous nor infected with vice and cruelty In extremely small groups, with a limited range of interests and activities, we cannot look for cultural phenomena, fully fledged, formalized, and with a strongly pronounced moral physiognomy Under such conditions, it depends very largely upon the subjective stress given by ethnographer or scholar in one direction or the other, upon some minute touching up, whether the Bushman, the Negrito or the Australian aborigine emerges as a happy child of Nature or a miserable savage witch haunted, starved and bloodthirsty

The simple *yea* or *nay* approach is not sufficient We have to search in the confused and uncrystallized beginnings of social and mental life, and look for the manner in which law and order, rank and class differentiation, though but partly formed, yet do their work and achieve their results We have to establish the early forces and foundations of such permanent aspects as economics political rule administrative and legal order, education and religion

As regards all such problems within the sphere of early social differentiation, the present book will prove an excellent compendium of fact and information In his actual handling of most problems, Prof Landtman writes not as a follower of Rousseau, nor of the doctrines of Marx, Durkheim or Hegel, but as an impartial man of science, one of the world's foremost field-workers, and with a sound theoretical outlook derived from the unimpeachable teachings of Westermarck

The greatest merit of all original contributions to a new subject-matter is to provoke thought and even criticism, as well as to provide the material with which this can be substantiated Thus even my critical remarks are a tribute to the value of the book It will remain a standard treatise on the somewhat neglected, and nowadays perhaps most important, problem—that of human inequality, of the possibilities of a 'classless society', and the organization of rank and power

B MALINOWSKI

Periodicity of Earthquakes

Studies on the Periodicity of Earthquakes
By Dr Charles Davison Pp ix+107 (London Thomas Murby and Co 1938) 13s 6d net

> When the earth s crust or a portion of it is on the point of making one of those sudden movements that result in earthquakes a very slight force acting in the same direction may precipitate the movement On the other hand the same type of force acting in the opposite direction may be sufficient to delay its occurrence If the magnitude of the force in whichever direction it acts is subject to a periodic variation as in annual or diurnal changes of barometric pressure the same or a contrary periodic variation may thus be impressed on the frequency of earthquakes in any district The study of the periodicity of earthquakes may therefore throw light on both small and great movements of the crust

THESE opening words from the preface of Dr C Davison s new book clearly indicate the motive that prompted this veteran worker on earthquakes to undertake one branch of his extensive seismic studies Much might be written on the mechanical questions involved in these prefatory remarks without invalidating the legitimacy in our present state of ignorance of inquiry into the periodicity of earthquakes Such an inquiry forms a natural complement to the author s long and valuable work in collecting and cataloguing particulars of the earthquakes that occur both in the British Isles and throughout the world as a whole His book summarizes and extensively revises (with the aid of many new catalogues) the conclusions on earthquake periodicity that he has published in many articles during the past forty years and more

The periods Dr Davison has been led to consider range from forty two minutes through diurnal and annual intervals to eleven and nineteen years a chapter is devoted to each supposed period The brief opening chapter describes the method employed and the test of reality adopted which is one given by Schuster the author states that the test may be and often has been misapplied but is himself convinced that as he applies it it establishes the reality of the periods studied in each of his chapters In his concluding chapter he discusses how the results he obtains throw light on the movements of the earth s crust

Those who know most about the pitfalls that beset statistical studies not least in geophysics will probably feel that Dr Davison s conclusions should be taken as a new starting point rather than as the end of this line of investigation Not the least valuable feature of his book is the long list of (131) catalogues of earthquakes on which his studies have been based and which will facilitate new studies of the same data as for example by the methods that Bartels has developed wherein in particular quasi persistence is taken into account

Electronic Theory and Organic Reactions

Modern Theories of Organic Chemistry
By Dr H B Watson Pp viii+218 (Oxford Clarendon Press London Oxford University Press 1937) 15s net

A BOOK such as that under review was certainly wanted in order to co ordinate the various modern theories applied mainly to organic chemical reactions Thus after a general article on theories of chemical combination—a theme which has occupied the minds of chemists from the earliest days and will do so for many years to come—the author passes on to deal with the new physical methods of investigation and devotes many pages thereafter to a general discussion of the subject, mainly of the electronic theory as applied to organic reactions Although Robert Robinson gave a very concise and clear account of this theory in his lectures at the Institute of Chemistry in 1932 the work which has been done since needed the hand of a ready writer in order to co ordinate the details in a manner capable of being understood by those who are not physically minded The desired co ordination is provided in this book and the author is to be congratulated on the way in which he has achieved a most necessary task

Nevertheless it must be admitted that except in the instance which may be termed The Royal Institution Case the theory has not yet proved sufficiently quantitative to enable it to predict It still relies too much on what is known and on what indeed has been recognized and provided with other forms of nomenclature, in the past The positive negative cause of all chemical reactions has been the basis of discussions of interacting molecules for generations past What we require of the new theory, and what it has not yet developed to the full, is a quantitative aspect which will give direction and not merely offer an explanation of what is known No doubt, however, this development is only a question of time, and the research worker will at some future date be able to tell with certainty whether an organic reaction will 'go' or not Then, and then only, will the investigator save the time and expense caused by the 'cut and try' method of research a method which is perhaps more common than many purists will admit

The chapter on Free Radicals" is also one of considerable interest That the combination of organic residues to form more complex molecules occurs is clear but what is lacking in this method is direction When the simplest cases are investigated, that is, for example, those cases in which only two free radicals are concerned, all is clear It is only when several such free radicals are involved that the issue seems to be entirely adventitious and may be likened to a dog fight It is foolish to dogmatize in these matters, but it seems unlikely that, except in specific cases, this method of research can lead to any form of prediction open to serve any useful purpose

The article on tautomeric change is admirable, and will repay reading, as will also the chapter on "The Beckmann Rearrangement" and those on several other topics of the day

The book is well presented and well written throughout, and contains just those matters which the chemist as such, apart from the specialist, wishes to know To the specialist himself it will act as a stimulant and an incentive J F T.

Scientific Pursuit and Personality

Scientists are Human

By David Lindsay Watson (The Library of Science and Culture) Pp xx +249 (London Watts and Co , 1938) 7s 6d net

IN his foreword, Prof Dewey says that Dr Watson is concerned to show that the pursuit of science and the products of science are relative to the mental world of the scientist, to the organization of his personality in all its phases, and that this in turn is relative to the social organization that subsists" That is surely a commonplace nowadays , the only dispute left is that between liberals and communists concerning the relative importance of personality and social organization

Dr Watson is very definitely liberal , indeed, he scarcely seems aware that the communist view is held seriously The first part of his book is directed to an inquiry whether the social organization that subsists in the United States is favourable to the personality of those possessed of true scientific originality He concludes that it is not I am quite incapable of offering any opinion concerning the matter, because the conditions he takes for granted in America do not prevail in Great Britain We doubtless suffer from our own evils , but our universities do not, I think, over value "drawing-room standards" , nor would eccentric genius find its spiritual home here in an industrial rather than in an academic institution

But even an American reader might criticize Dr Watson's analysis He seems to assume that scientific genius is always associated with the same kind of personality and that conditions adverse to one genius must be adverse to all This is by no means obviously true , it is difficult to imagine a state of society that would be congenial both to a Cavendish and to a Rutherford , it is equally possible that almost any state of society will encourage some type of scientific genius Moreover, Dr Watson's arguments are difficult to follow He is obsessed with neglected geniuses , but whatever were the reasons why Fresnel and Mendel did not receive their full recognition, they were certainly not the machinations of the ' good executive" to which (I understand) all American evils are due Again, the fact that Dr Watson thinks that certain of his contemporaries are neglected surely does not prove that they are geniuses , the judgment of contemporaries is *sometimes* right It is all very puzzling

The rest of the book is concerned with the denunciation of certain fallacies that, according to Dr Watson, vitiate much of modern science (Whether they too are due to the "good executive" is not clear) The difficulty here is to discover who entertains these fallacious doctrines , for whenever Dr Watson quotes a scientist (even myself !), he does so with approval Moreover, the true gospel, as he expounds it, does not seem to be very novel , it appears to be made up of selections, not always self-consistent, from all the chief writers on scientific principles and methods I am sorry to be so disparaging, for Dr Watson's theme is interesting , but his personal grievances appear to have got the better of his judgment

NORMAN R CAMPBELL.

The Doctor's View of War

Edited by Dr H Joules Pp 123 (London George Allen and Unwin, Ltd , 1938) 3*s* 6*d* net

THIS admirable little volume has the strongest claims on the attention of all scientific workers Dr Joules and his colleagues give a concise but lucid account of the service which the doctor can render in time of war, and the problems he has to face, as well as of the effect of the disregard of the Red Cross emblem in recent years Much more than this is, however provided An ably written chapter deals succinctly with the biological effects of war, and argues that it is doubtful whether a differential mortality between different groups would be great enough to have any evolutionary significance within a short time It is considered rather that modern war would wreck the present structure of society without any permanent biological damage having been inflicted

It is however, for the stimulating and highly suggestive chapters which deal with the professional responsibilities of the doctor towards the State and in the defence of the civilian population that scientific workers should be most grateful What is written here of the medical profession is equally true of scientific workers of other groups, and the problems which face a professional association in relation to the State and the responsibility that such associations must bear for independent investigation and criticism are admirably presented If the volume did no more than arouse scientific workers to the responsibility that they must bear in this way for conserving the fragile life of our democratic institutions it would be welcome It issues, however, a call to wider action on an international scale to eliminate the causes of war, and the responsibility of the doctor or other scientific worker as a private citizen for supporting a foreign policy which insists on such preventive measures is firmly urged Equally it is urged in conclusion that the medical associations of different countries should take their own collective action to assure ordered scientific progress, nationally and internationally conceived and practised, and that the relations of the profession to the State should be based upon a series of well defined principles

These Amazing Electrons

By Raymond F Yates Pp xiii + 326 + 46 plates (New York The Macmillan Co , 1937) 16*s* net

THIS volume merits serious consideration as an attempt to popularize science, with proper emphasis on its social significance It is not a mere book of wonders (although they are in it), but an accurate and well illustrated account of the principles and applications of electronics The development is not superficial, but it should be possible for anyone to follow it easily who has no more initial knowledge of electricity than is required for the use of ordinary domestic electrical apparatus Mr Yates's style is vivid, almost racy, and will probably irritate an academically trained physicist , but it is unlikely to disturb the average lay reader

Advanced Algebra

By Clement V Durell and A Robson Vols 2 and 3 Pp xi + 195–510 + xxiii–xlvi + 4 (London G Bell and Sons, Ltd , 1937) 12*s* 6*d*

THIS book, comprising vols 2 and 3, is intended to complete the school course and to provide a suitable introduction to higher work for those who are proceeding to the universities Attention has rightly been concentrated upon fundamental principles and methods which are essential to a more advanced study of modern mathematics Vol 2 deals with finite series, difference equations, complex algebra, partial fractions, theory of equations, sequences and convergency In vol 3, the student is introduced to those parts of the subject which are of special significance in the modern developments of mathematics—inequalities determinants, matrices elementary probability and the theory of numbers

Throughout, the text has been prepared with much skill, thoroughness and clarity , the methods are up to date and admirably adapted to lay a sound foundation for further study There is also an abundance of exercises for the student and these are roughly divided into two groups, the first consisting of straightforward applications of the bookwork, and the second of carefully graded sets of more difficult problems The book should be very useful and especially to those who intend to specialize in mathematics

Engineering Electronics

By Donald G Fink Pp xiii + 358 (New York and London McGraw Hill Publishing Co , Ltd , 1938) 21*s*

THE author, who is managing editor of the well known journal *Electronics*, is in an ideal position for observing the continuous and successful application of electronic devices to industry Without the subtlety associated with the specialist and research worker, or even a professor, and taking a robust point of view, he has produced a well balanced text covering ground which has indeed been covered before, but not in a way that a practising engineer can, and ought to, understand Sufficient theory of electrons in vacuum and gas tubes is included to make the internal and external circuit phenomena of these intelligible A large number of electronic problems serve to illustrate magnitudes and the possibility of practical use of controls

L E C H

The Climates of the Continents

By W G Kendrew Third edition Pp xii + 473 (London Oxford University Press, 1937) 21*s* net

THE third edition of Mr Kendrew s book does not bear any striking outward marks of differing from the earlier editions, but many minor emendations have been made, both in the text and in the tables The book remains, as before, the most useful and convenient collection of climatic data available in the English language, and not the least of its virtues is that it gives data for the whole world in one set of units

High Altitude Cosmic Radiation*

By Prof P M S Blackett, F R S

VERY great advances have been made during the last year in the understanding of the complicated phenomena of cosmic radiation One of the most important steps has been the experimental verification of the validity of the predictions of the quantum theory of radiation up to very high energies The application by Heitler of the quantum theory to the collisions of energetic electrons with atoms and also the semi classical treatment of the same problem by Williams and by Weizsacker show that energetic electrons are rapidly absorbed in matter by the emission of energetic photons and further that the photons are equally rapidly absorbed by the production of pairs of positive and negative electrons The combination of these two processes leads to the cascade theory of showers which was developed independently by Bhabha and Heitler and by Carlson and Oppenheimer When an energetic electron traverses an absorber it gives rise by successive acts of photon emission and pair production to a large number and for very energetic electrons to a very large number of positive and negative electrons and photons Eventually the loss of energy by ionization brings this process to an end leading after the first building up of a shower to its eventual absorption

This cascade theory of showers was found to explain in a very satisfactory manner the behaviour of the soft component of the cosmic rays in the atmosphere in particular the measurements at high altitudes by Regener and by Millikan and their co workers The theory was also able to explain many of the features of the much studied transition curves of showers and bursts in dense materials which were first investigated by Rossi and Hoffmann respectively The details of the building up of cascade showers can be seen in cloud photographs some taken by Street and Stevenson are especially notable in this respect

Once the validity of the quantum theory for electrons with energies of 10^{10}–10^{11} electron volts had been established it became certain that the penetrating rays which are in the great majority at sea level must consist of a new type of particle with a mass intermediate between that of an electron and that of a proton The possibility that the penetrating component might consist of a new type of particle had been discussed by Auger in the course of a detailed discussion of the widely different properties of the hard and soft components

Neddermeyer and Anderson[1] first put forward strong evidence that the penetrating rays consisted of particles which had a mass intermediate between that of electrons and protons Cloud photographs taken by Anderson Street Williams Brode Ehrenfest and others have shown that the mass of the new particle is probably of the order of 150 times the mass m_e of an electron

Once the experimental existence of the new particle had been established great interest was aroused in a theory of nuclear forces put forward in 1935 by Yukawa[2] in which he had postulated the existence of particles with a mass of about 100 times the electronic mass in order to explain the short range nuclear forces by assuming that this field was related to the emission and absorption of such hypothetical new particles in a similar way to that in which the coulomb forces between electrons and nuclei are related to the emission and absorption of photons On this view the range of the nuclear forces which is of the order of the classical radius r_0 of the electron and so the size of the fundamental heavy particles is essentially related to the mass of the new particle through the relation $\lambda = \hbar/\mu c$ where λ is its Compton wave length and μ is its mass If $\mu \sim 137\, m_0$ then $\lambda \sim r_0$

In order to explain β decay Yukawa assumed further that the new particle interacted with electrons and neutrinos It followed that the new particle if it existed in the free state must be itself β active that is it must disintegrate spontaneously into an electron and a neutrino with such a probability that its mean time of life when at rest is given by

$$T_0 = 3\hbar^2/g^2 \mu c$$

where g is Fermi s constant of β decay Taking $g \doteqdot 4\times10^{-1}$ and $\mu = 200\, m_e$ we get $T_0 \doteqdot \frac{1}{2}\times 10^{-6}$ sec When moving very rapidly the particle will live longer owing to the relativity change of time scale as pointed out by Bhabha[3] and so will have a mean time of life $T = \gamma T_0$ where $\gamma \gg 1$ and is the ratio of the total energy of the particle to its rest energy

The predicted instability of these particles provides an immediate explanation of the curious fact that had been deduced from the observations by several workers, that there are apparently no penetrating particles incident as primaries on the top of the atmosphere on the new theory they would, of course have disintegrated in space before reaching the earth Recently, Heisenberg and Euler[4] have shown how the spontaneous decay of the new particle can explain the striking, but hitherto inexplicable failure of the mass absorption law for the penetrating rays in air and in dense materials

---

*Introductory address at a symposium in Section A (Mathematical and Physical Science) of the British Association on August 20

By observations at ground level and in the tube station at Holborn Follett and Crawshaw[5] found that the intensity of the rays under a large thickness of air was about one half that found under the same mass of clay Ehrmert[6] found a similar discrepancy between the absorption by air and by water The effect was studied in considerable detail by Auger[7] and his co workers who obtained results which can be interpreted as showing the greater absorption of air at low pressure compared with air at normal pressure

Heisenberg and Euler show how such observations can be explained quantitatively by the spontaneous decay of the new particle This follows from the fact that in air the distance travelled by the particle during its mean time of life is rather less than its range as defined by its ionization loss, whereas in dense materials the latter range is very much the smaller Thus in air the decay increases the apparent absorption while in dense materials it has little or no effect

A simplified form of the calculations of Heisenberg and Euler shows clearly how the order of magnitude of the time of decay can be obtained from the observations For example, from the measurements of Follett or of Ehrmert it can be seen that the intensity under 60 m water equivalent of air is about a half that under the equivalent thickness of clay or water We conclude, therefore that one half the rays decay spontaneously in the time required to traverse 60 m water equivalent of air that is a distance of about 60 000 m The mean time of life T is therefore of the order of $6 \times 10^4/3 \times 10^{10} \simeq 2 \times 10^{-6}$ sec Since the value of γ for the rays assuming a mean energy of 10^{10} e volts and a mass of 200 m_0, is about 100 we get $T_0 = 2 \times 10^{-8}$ sec Though this value is about four times that predicted by Yukawa the agreement must be considered as most satisfactory in view of the early stage of the theory and of the crudeness of the deductions from the experiments

There seems therefore to exist definite experimental evidence for the spontaneous decay of the new particle The accurate determination of this time of decay and of the mass of the particle is now one of the outstanding problems of cosmic ray research It is possible of course that there are other methods than that of spontaneous decay by which the new particles may disappear but further experimental results are needed before any certainty can be attained on this point Since there can be no particles of this type incident on the atmosphere they must all be produced in the atmosphere as secondaries to the incident electrons No evidence as to how this occurs has yet been found

The Old Stone Age in European Russia*

ARCHÆOLOGISTS are generally agreed as to the importance of obtaining more precise and detailed information about the actual conditions of the cultural stages of eastern Europe, of which the greatest part is European Russia At the same time, the total of information relating to the palæolithic period in that region, which has appeared in English, French and German, is negligible, and knowledge of the period is far from satisfactory Dr Golomshtok, accordingly, at the suggestion of Mr H H F Jayne director of the University Museum of Pennsylvania, with the assistance of the Board of Managers of the Museum and a grant from the National Research Council has brought together all the data available, regardless of the language of publication, but so far as possible endeavouring to present the first hand evidence of the excavator Some idea of the importance and magnitude of his undertaking will be gathered from the fact that while Burkitt lists nine sites, MacCurdy fourteen, and Ebert and Menghin six and seven respectively the present survey, which it is pointed out, is not to be regarded as final, covers no fewer than 105 sites to which must be added eight sites on which human remains have been found, without artefacts, but in association with a fossil fauna, or otherwise dated

---

* The Old Stone Age in European Russia By Eugene A Golomshtok *Trans Amer Phil Soc* N S 29 2, March 1938 Pp v+191–468+xxxvii plates

In the history of palæolithic studies in Russia up to 1917 the first site discovered was Gontzi in the Poltava region, where fossil bones in association with a flint implement attracted the attention of Kaminsky a local teacher, in 1874 Three years later Count U S Uvarov, the father of Russian prehistoric archæology, established the existence of a palæolithic site on his estates near the village of Karacharovo and in 1879 his collaborator, Poliakov, discovered Kostenki I one of the most important sites in Russia The visit of K S Merezkovski a botanist, to the Crimea resulted in the discovery of a number of cave sites Suren I Cherkess Kermen etc , while from 1880 onward palæolithic cultures were determined in the Dnieper region (Antonovitch) Nova Alexandria (Kristaphovitch) Tomsk (Kaschenko) Cyrill St , Kiev (Khvoiko) and Ilskaya in the Caucasus (Baron de Baye) Uvarov and Volkov, by their summaries of existing knowledge, and the latter also by training young archæologists in his excavations at Mezine (1908) placed palæolithic researches in Russia on a truly scientific basis Among Volkov's pupils, P P Ephimenko is the most distinguished archæologist in Russia of to day

Under the Soviets, archæological studies have received a tremendous impetus, and the interest of the general public has been much enhanced Old sites have been re examined and new sites opened In 1922, Zamiatnin discovered and examined Borshevo near Kostenki where also he excavated new sites Important investigations have been carried out by G A Bonch Osmolovsky among others in the Crimea In Siberia, extensive studies have been made in the Yenisei district and in the region of Irkutsk , while archæology has been supplemented by a more detailed study of quaternary geology and palæontology by Pavlov, Gromov and others The only survey of this work hitherto in a language other than Russian is by L Sawicki , but it is in Polish

The materialistic interpretation of history now followed under the Soviets requiring the investigation of every factor that influenced culture, expeditions have studied, alongside the archæological and ethnological data, local geology, fauna, flora and climate Microscopic examination of charcoals have afforded much information as to flora and climatic conditions

Russian students of the development of culture, being firm believers in the evolutionary materialistic explanation of cultural changes, are strongly opposed to the theories of cultural borrowings and migrations of Western archæologists, as well as to the antiquarian attitude of interest in antiquities *per se*, which forgets the people who made them Again, Russian archæologists claim that their statistical and functional methods of study have, on one side, saved them from laying undue stress on 'leading' types, which give a distorted view of the culture, and on the other they have been led to such discoveries as those of underground dwellings of palæolithic man which have been overlooked in the West

Before turning to archæological discovery the conclusions of recent geological and palæontological investigations may be summarized as follows The existence of three and only three definitely traceable glaciations has been established These are Mindel Riss and Wurm The Gunz was very weak and either its traces were obliterated by subsequent advances of the ice or it was not effective The other three glaciations appear to correspond in time and in general characteristics with those of western Europe The fauna which accompanied the various climatic changes generally corresponds to that of western Europe but on the whole has a colder character The extremely warm species are few and not abundant The Crimea and Caucasus show local variation

The discovery which has probably attracted most attention among Western archæologists in the post War years is that of the human skeletal remains, generally known as the Podkumok skull from the Caucasus These remains were found in the autumn of 1918 in the course of excavations for a sewer in the town of Piatigorsk They were below a pottery vessel and a polished stone perforated disk , but owing to political conditions no observations of the exact position of the human remains was possible Later the remains were dated on the basis of general geological conditions resulting from a survey by P V Rengarten According to this, the find was in the fifteen metre terrace of boulder clay deposits on the left bank of the Podkumok River General conditions for the North Caucasus show three terraces at 15 m , 60 m and 120 m respectively, all belonging to the Quaternary Age On this showing the Podkumok find belongs definitely to the Würm glaciation

The Podkumok remains are part of a cranium consisting of almost the whole of the frontal bone, the front parts of both temporal bones and a small part of the nasal bone, a fragment of the right side of the lower jaw with five teeth, and some other fragments of the skull and skeleton The bones are thin and small and the muscular attachments weak Gremiatsky identifies the remains as those of a female of from fifty five to sixty years of age of the Neanderthal group, but showing an approach to *H sapiens*, which would place it between Neanderthal and 'modern man'

While Gremiatsky holds that this find definitely establishes the existence of Neanderthal man in the Caucasus in conditions very similar to those of the diluvial period of western Europe, there has been a disposition recently in Russia to question the Neanderthal affinities of Podkumok, while Sir Arthur Keith, it is noted, has expressed the opinion that it is altogether of the neanthropic species.

In this connexion, it is to be remarked that the biological conception of the development of man favoured by Soviet archæologists pictures that development as one uninterrupted chain of evolution, and the view of Western archæology that the Neanderthal race died out and was replaced by a new Cro-Magnon race is vigorously denied. Cro-Magnon is considered to be a direct descendant of Neanderthal man, and it is held to be even possible that this transformation may have taken place in Europe.

A number of human cranial fragments have been found with fossil bones of an extinct fauna at several sites on the Lower Volga. Of these the most considerable are known as Undora I and Undora II, from the island of that name on which they were found. The skulls have been reconstructed by A. P. Pavlov, and classified by him as belonging to a group which includes Galley Hill, Brunn and Canstatt, of early post-glacial date.

The dating and interpretation of cultural finds by Soviet prehistorians are often founded on certain basic assertions, which lead to important divergences from the views held by Western archæologists. The acceptance of the universal evolutionary scheme of cultural development with the material basis as the main determinant, results in a fairly well outlined succession of the phases of social structure, corresponding to the different stages of industrial development. The centre of gravity lies in the method of production, and strenuous objection is taken to 'migrations', 'borrowing' and 'superior races'. This view, however, leads to certain difficulties and inconsistencies. Ephimenko, for example, when faced by certain very primitive characters in Neanderthal man, attributes them to the degeneration which arose from close interbreeding in the small Neanderthal group. Yet on the other hand, the relatively poor industry of the Mousterian group is taken as a proof of the tenacity and ingenuity of Neanderthal man.

To account for the superior physical characters and industry of Cro-Magnon man, it is argued that new conditions of existence changed the character of the social structure, creating, in place of the closed primitive horde, more complex groups of intercommunicating hordes. Hence arose rapid cultural growth and the formation of a new physical type, which entered the history of Europe during the Upper Palæolithic period as the Cro-Magnon race. This view, it is only fair to say, is not accepted by all Soviet archæologists. Bonch-Osmolovsky maintains that while Neanderthal man differed physically from modern man, these differences were such as to limit his functional possibilities. Thus the structure of his hands prevented him from making long knife-like blades which required a very accurate blow for their detachment. Hence Neanderthal man and Cro-Magnon man represent stages in the process of perfection, which are the result of physical changes dictated by the gradual development of social life.

On summarizing the material from the one hundred and thirteen localities listed, certain generalizations are seen to emerge. European Russia would appear to be very poor in remains of Lower and Middle Palæolithic cultures. No true Chellean and Acheulean sites are found. Two accidental finds of *coups de poing* are doubtful, but a series of Acheulean sites reported in the Caucasus by Zamiatnin may change these conclusions when data are available. The so-called 'pre-Mousterian' cultures, such as are found in the lower layer of La Micoque and La Ferrassie, are represented by the lower layer of Kiik Koba. The dating of this site, however, is far from settled. The upper layer is regarded as pre-Mousterian or archaic Mousterian. Transitional between Middle and Upper Palæolithic, corresponding to Abri Audi, is Shaitan Koba. These sites are dated by Gromov as from Riss-Wurm to the maximum of Würm.

In the Upper Palæolithic there is an absence of stratigraphical evidence of distinctly different cultural layers. In the cave sites of the Crimea and the Caucasus where geological evidence is lacking, it is frequently necessary to rely on analysis of the faunal complex. The bulk of Upper Palæolithic sites are open camp sites of hunting peoples. In these two cultural complexes can be distinguished. The first of these complexes consists of large accumulations of animal bones, very much like the well-known bone piles from Předmost, Moravia. As a rule they contain very few stone implements. The second complex, according to most Russian archæologists, represents the place of more or less permanent habitation of these hunting groups. It is characterized by red pigmentation of the ground, due to the presence of ochre, the remains of open fires, filled with ashes and charred bones, and usually by large quantities of stone and bone tools. In several cases, definite traces of permanent habitations were found, sometimes with stone slab foundations, well-preserved fireplaces, copings, niches in which objects were kept, and caches of flint and bone tools. Nearby were storage pits and primitive 'ovens'.

The flint industry of the Russian Upper Palæolithic presents almost every variety of form known to western Europe except the very specialized classical 'Solutrean The 'leading' bone forms, such as the Aurignacian cleft base and harpoons, are totally absent Consequently an entirely new set of criteria for dating is necessitated, and the subdivisions of Upper Palæolithic industries are employed with different implications Aurignacian Proto Solutrean Solutrean and Magdalenian are used to designate stages in the development of culture, rather than specific cultures Thus bifacial flaking and the *point à cran*, even in its most atypical form, are taken as indicating Solutrean temporal affinities Taking this as the middle point, industries where these characteristics are less prominent are taken as older, that is as Aurignacian others which show a general decadence of technique are said to be younger, that is, Magdalenian Hence Ephimenko finds true Aurignacian in one site only, Suren I The rest of the Upper Palæolithic sites, excluding the transitional with microlithic industries he classifies as Aurignacian Solutrean and Solutrean Magdalenian, affirming that no true Solutrean sites are known in Russia

Basically, we seem to have in European Russia the Early, Middle and Late Upper Palæolithic industries all characterized by the blade technique, which starts very much like the Aurignacian in western Europe, develops, acquires some peculiar traits, suggesting Solutrean influence, and then slowly degenerates, finally reaching the stages of a microlithic industry

Hugh Miller, 1802-56

Commemoration at Cromarty

THE rise of geological knowledge in the first half of last century was marked by the appearance of innumerable books dealing with the rich mass of observations which could be made by even superficially interested persons Most of these books are wisely forgotten, but in the residue there are some of the strongest foundations of the present science One stands out among the greatest, both in content and in its influence on others "The Old Red Sandstone or New Walks in an Old Field" by a man who was proud to be a journeyman mason Buckland said that "geologists were amazed and delighted" by this book, and his phrase must be echoed to day, almost a century later

Hugh Miller wrote other books, many of them dealing with geological topics, but "The Old Red Sandstone" seized popular imagination and made this perhaps the most widely known geological formation He had a few comments on the geology of his native Cromarty in "Scenes and Legends of the North of Scotland", which was appreciated by distinguished critics for its literary qualities "The Old Red Sandstone" was published serially in 1840 in the *Witness* newspaper, of which Miller was editor, it appeared as a book in 1841 "Footprints of the Creator, or the Asterolepis of Stromness", followed in 1847 as a reply to the "Vestiges of Creation", in which Chambers had published anonymously an evolutionary theory Miller's answer was, in its time, a remarkable and able contribution to Christian apologetics He dealt further with the hotly debated frontier-territories of science and religion, in "The Testimony of the Rocks" (1857), which received its final corrections on the day of its author's death, and in the same year was published "Voices from the Rocks, or Proofs of the Existence of Man during the Lower Palæozoic Period", which is now best forgotten Posthumously, in 1858 Symonds edited the manuscript of "The Cruise of the Betsey, with Rambles of a Geologist", which, in my opinion, contains the most delightful prose of all Miller's output Other less important geological books and papers, besides other works, came from his pen

To Hugh Miller geology was an incident in the revelation of religion, but he was usually a shrewd and accurate observer who faced the deductions which he could make from the facts of his observations In the dedication to "Footprints of the Creator" he wrote "The ingenious and popular author [Chambers] whose views on Creation I attempt controverting, virtually carries his appeal from science to the want of it I would fain adopt an opposite course" He was a strong believer in the notion of successive creations, and the great profusion of fossil fishes in the nodule-beds which occur at certain levels in the Middle Old Red Sandstone of the Moray Firth led him to describe these horizons as "platforms of death" For some time his efforts were directed to reconciling Biblical and geological knowledge, and in the atmosphere of nearly a century later it is not always easy to estimate the influence of these attempts

His indignation was powerfully aroused by two things—the clearings in the Highlands, during which large sections of the crofter population were packed off to the colonies, and the system of patronage then prevalent in the Church of Scotland Some tracts published in 1839 made a very deep impression, and in 1840 he was persuaded to become editor of the *Witness*, the organ of the non intrusionist party His energies had found a congenial outlet, and his conduct of the newspaper played a great part in the events which led to the formation of the Free Church

The scientific content of Miller's geological work is perhaps magnified by his literary qualities, but it can stand on its own merits It must be remembered that very little was known at that time of the comparative anatomy of *living* fishes, and it is not at all remarkable that Miller made several mistakes in his accounts and reconstructions of the curious fishes of the Old Red But these were mistakes in the interpretation and synthesis of a great number of new, accurate observations which he made on the actual fossils Sir Archibald Geikie wrote "He was not in any sense a trained geologist He lacked the habit of patient and detailed investigation in departments of the science that did not specially interest him, but which were essential as a basis of accurate induction and successful speculation", though perhaps T H Huxley's was a fairer appreciation 'The more I study the fishes of the 'Old Red' the more I am struck with the patience and sagacity manifested in Hugh Miller's researches, and by the natural instinct, which in his case seems to have supplied the place of special knowledge "

It is often assumed that because men like Hugh Miller and Robert Burns were of humble birth and were manual workers that they were without education, but the Scottish parish school system was proof against that Miller himself said that his want of the more orthodox learning was largely his own fault As for Latin he wrote at thirty six years of age I abominate it and ever did since I burned my *Rudiments*" and Latin was a hall mark It is recorded that his uncles were prepared to assist him to King's College at Aberdeen, but he became a stonemason against family advice From his work he contracted silicosis, which ruined his health, and in later years his mind became affected and he shot himself in 1856

Though Miller wrote much on other geological topics (for example, the shelly boulder clays of Scotland), it is particularly with the Old Red Sandstone and its fossils that he is associated He came early under the influence of Dr John Malcolmson and Prof Fleming, and later corresponded with Agassiz and with Murchison (who was also a native of the Black Isle) On the other hand he was regarded by many geologists in north east Scotland as their mouthpiece, and such men as Robert Dick of Thurso kept him informed of their new discoveries and sent him specimens without which much of his work would never have been written

Miller was born of mixed Scandinavian Scottish and Celtic stock at Cromarty in 1802 and the cottage in which he was born was handed over to the National Trust for Scotland on September 26, 1938

News and Views

Dr C. G Darwin, F R S

THE Lord President of the Council has appointed Dr C G Darwin, master of Christ's College, Cambridge, to the directorship of the National Physical Laboratory, rendered vacant through the ill health of Prof R H Fowler, who is unable to take up the post The name of Darwin is so completely identified in popular speech with the author of "The Origin of Species that it is not always easy to give due credit to the work of his illustrious descendants Dr Darwin is a grandson of Charles Darwin, and a son of the late Sir George Howard Darwin, formerly professor of astronomy at Cambridge He is distinguished for his work in mathematical physics, especially for his researches in collaboration with R H Fowler on statistical mechanics (1922) and on the quantum theory of the electron and the atom (1927) He described the electron as a vector wave having two independent components analogous to the polarized components in a wave of light Much of this later work was done while Darwin occupied the Tait chair of natural philosophy in the University of Edinburgh There, as a colleague of Prof E T Whittaker, he did much to strengthen the mathematical school in the University and at the same time his influence was exerted on the council of the Royal Society of Edinburgh The striking address which he delivered at Cambridge this year as president of Section A (Mathematical and Physical Sciences) of the British Association has been described as a model which other sections might study

Dr. Alexander Scott, F R S.

THE announcement of the retirement of Dr Alexander Scott from the honorary directorship of research at the British Museum Laboratory brings to mind that he was a pioneer in a field of applied science which, largely through his initiative and vision, has developed beyond all expectations The idea of having a scientific laboratory in an archæological museum was entirely novel, when, in 1919, the trustees of the British Museum sent a request to the Advisory Council for Scientific and Industrial Research for assistance in connexion with problems of cleaning, restoring and preserving antiquities That Dr Scott was called in to advise was singularly fortunate His wide knowledge of chemistry coupled with his interest in antiquities fitted him peculiarly for the work Within seven years the original inquiry had been satisfied and the results published in three reports which aroused widespread interest Early experiences were of incalculable value when he visited Luxor and co-operated with Dr Howard Carter in preserving many valuable objects from the tomb of Tut ankh Amun As experience accumulated, the fact emerged that scientific assistance could be of much greater value to archæology and the British Museum in general than had been at first supposed There were questions of authenticity, of the composition of materials, of ancient technique, of classification, and of general diagnosis that could be answered only with the help of qualified scientific staff having the necessary facilities Dr Scott has had the satisfaction of founding and controlling the development of a research laboratory which from small beginnings became at length (in 1931) incorporated as a department of the British Museum, and is recognized to day as being of the first importance by archæologists and museums the world over

Rejoinder of an Egg Collector

To Mr Edgar P Chance all credit is due for his film of cuckoo life, which thrilled every ornithologist who saw it and made a distinct contribution to scientific knowledge This achievement, however, does not necessarily justify all his other activities, and for his egg collecting he has been severely criticized His rejoinder appears as an eight page pamphlet entitled An Egg Collector Replies to his Critics" (Sept 1938) In our view, an appropriate reply would be to show that the amount of disturbance caused to wild birds was justified by the amount and value of the scientific knowledge gained from the collections and published for the information of other scientific workers Unfortunately, this reply makes no attempt at such justification, and is marred by expressions which cannot further the case of the egg collector The author s ethics are hinted at in a paragraph which states that ' Bird Protection laws are proverbially stupid [we have not heard any proverb on the subject] When a law is not worthy of respect it ceases to be law to those who know better" That is a position which cannot be defended, any more than can be the allegation that the bird protection laws are framed "by those who do not understand their subject" Clearly, however, the collector is himself convinced that his collection, which "is complete and only the abnormal can now find a place there", has been brought together without any unwonted disturbance of the numbers or distribution of wild birds

Accessions to the British Museum (Bloomsbury)

AMONG the accessions to the British Museum (Bloomsbury) reported at the meeting of the trustees on October 8 (the first meeting to be held after the recess) were a number of antiquities from Central America, part of the collection made by the late Mr T W Gann, and bequeathed by him to the Museum They were accepted by the trustees in May last, but this selection has been received at the Museum only recently The more important specimens are a number of carved jades, including figures of men and animals, coming mostly from Copan in Honduras The best example is a magnificent green jade plaque with figures carved in relief It is said to be the finest known example of carved jade from Central America It was found at Teotihuacan in Mexico, but is thought to have come originally from Quiriqua in Honduras By its style it is assigned to the Old Empire of the Maya, and dates probably from the fifth century A D In addition the bequest includes a number of fantastically shaped flints of unusual size Some of these range up to seventeen inches long There are also a number of painted stucco heads, with elaborate headdresses and some beautiful examples of the Mayan painted pottery Another accession to the American collections obtained by purchase is an archæological collection from Esmeraldas Province, Ecuador, while an anonymous loan consists of a notable series of antiquities from mexico, which includes a remarkable series of funerary urns in human shape from Oaxaca The Museum has now received its share of the antiquities found by Sir Leonard Woolley and Mr M E L Mallowan on their respective expeditions in Northern Syria, which were conducted under the auspices of the Museum jointly with the School of Archæology in Iraq Grants have been allocated for the renewal of both these expeditions in 1938–39

Excavations in Northern Syria

MR M E L MALLOWAN's expedition to the Habur region of Northern Syria in the spring of 1938, from which came the finds to which reference is made above, excavated four areas, which in conjunction yielded evidence covering a period extending from 3100 B C down to 1500 B C The remains latest in date were Hurrian houses of mud brick in three successive levels, ranging in date from 1800 B C to 1500 B C These yielded a quantity of pottery of white design on black Some private houses, Mesopotamian in plan, were contemporary with the third dynasty of Ur, but the most important evidence was obtained from the Sargonid level with its Akkadian palace, and the ziggurat, or tower, of Jemdet Nasr date, of which the remains were found beneath the Palace The Palace, of which a complete ground plan was recovered, is a huge building, 90 metres by 90 metres, ranged about a great courtyard It was built, as is shown by an inscription, by Naram Sin, son of Sargon, about 2500 B C It was destroyed by fire approximately at the end of the Sargonid period and rebuilt under the third dynasty of Ur Below the south west corner of the Palace were the ruins of a great tower, which was built about 3100 B C Its dimensions were about 60 metres by 60 metres, and its walls still stand about 10 metres high It rests on a clay platform, and was found to be packed with votive offerings, among which were about 40,000 beads in a variety of material, though mostly of faience There were also a large number of amulets, which are beautiful specimens of animal carving and not all paralleled at Ur and Uruk A collection of alabaster idols consisted of about 200 complete figures, with some thousands of fragments

Excursion of the Geological Society of France

A R LILLIE writes The *réunion extraordinaire* of the Société Géologique de France was held this year on September 10–17 in the southern French Alps There was an attendance of ninety four members, who came from the following countries France, Belgium, Britain, Czechoslovakia, India, Poland, Spain and Switzerland The excursion, under the guidance of Profs Gignoux, Lory, Moret, Raguin and Schneegans was well organized and was a useful introduction to a territory of fascinating tectonic problems The party met at Grenoble, where M Gignoux outlined the objects of the meeting, and then went by motor car to the Dévoluy M Lory there demonstrated the considerable extent of the pre Senonian folding which he has elucidated during many years work From Gap as centre, during the following three days, the excursion was conducted in localities situated in the ultra Dauphinois zone and the sub-Briançonnais zone at Ancelle and in the Ubaye valley The recent work done in this region, particularly that of Schneegans in the massif of the Grand Morgon, is very impressive in view of the complicated tectonics and the mountainous nature of the ground Moving on to Briançon for the last three days of the excursion, the party had the opportunity of seeing something of the tectonics in the Briançonnais zone The final day was spent at the col du Galibier, where all the tectonic elements are to be seen continued northwards into Savoie An excellent memoire with numerous plates had been prepared by MM Gignoux and Moret in collaboration with Lory and Schneegans, and a copy was presented to each participant This memoire, entitled 'Description Géologique du Bassin Supérieur de la Durance", appears to include much hitherto unpublished work, and should prove a valuable summary for geologists interested in Alpine tectonics

The Mellon Institute

THE annual report of the Director of the Mellon Institute for the year March 1, 1937, to March 1, 1938, refers to the interest aroused in hydroxyethylapocupreine, a contribution of the Institute's department of research in pure chemistry Semi plant scale operations have been undertaken to provide material for more extensive clinical trials, and other new drugs prepared in the Institute have received clinical trials in cases of pneumonia and pneumococcic empyema Research on alkyl, hydroxyalkyl and other derivatives of apocupreine is being actively pursued with the object of finding more efficient antipneumococcic drugs Studies in the treatment of streptococcal and pneumococcal infections have been continued, and research on the variability of the tubercle bacillus has reached a point where it appears to be of some importance in diagnosing anomalous aspects of lung tuberculosis in the benign stages, an advance which may make it possible to use preventive and hygienic measures in time to stop development into the classical and more fatal forms Seventy two applied science programmes or fellowships were in operation in 1937–38, new fellowships on amines, anthracite industries, chemical hygiene, cotton, dielectrics, proteins and tar properties commencing operation in the year Valuable contributions to the improvement of industrial health have been made by the attention given to the medical, engineering and legal aspects of the problems involved A multiple fellowship on commodity standards has a programme directed to establishing standards for nearly 300 items of staple merchandise so as to provide known values for the consumer The Cotton Research Foundation is investigating the chemical and physical properties and uses of the whole cotton plant A new blue print paper has been developed, and a new resin, Raolin, is also under development A multiple fellowship on organic synthesis has been concerned with the preparation, properties and uses of a wide range of amines, solvents, intermediates and resins, including various alkylene alkylol and heterocyclic amines, propylene glycol derivatives, silicon and titanium esters of higher alcohols and vinyl resins for protective coatings

Industrial Development in 1937

A SURVEY of Industrial Development for 1937 recently issued by the Board of Trade includes particulars of factories opened, extended and closed in 1937 with some figures for 1936, and indicates the extent to which industrial development in the form of new factories and factory extensions took place in Great Britain in 1937, together with the areas in which it occurred and the nature of the trades contributing to such development (H M Stationery Offices 9d net) The survey is limited to factories where 25 or more persons are to be or have been employed, and Government establishments set up in pursuance of the rearmament programme are excluded The Survey shows that 541 new factories, employing 46,700 people, were established in 1937, as against 542 in 1936, employing 49,500 people The number of factory extensions, however, increased from 185 to 237 and the number of factories closed decreased from 394 to 361 94 of the new factories represent transfers from other areas and 66 of these are in Greater London An attempt was made to ascertain the reasons for the location of the new factories Convenience of premises was the reason given in 212 of the 416 cases for which particulars were obtained, suitability of labour coming next (67), proximity to other factories in the same industry (41), proximity to markets (34), cheap land, low rent or low rates (34), accessibility of raw materials (26), being the other reasons assigned in the relative order indicated

Greenkeeping Research

The report of the Board of Greenkeeping Research for 1937 (from the Board's Research Station St Ives, Bingley, Yorks 2*s* July 1938) shows an increasing amount of advisory work and original investigation at the St Ives Research Station and at other centres The Station lives within its income, but research work cannot be greatly extended with the present financial arrangements, as advisory work makes the first claim upon revenue More advisory work was, moreover accomplished in 1937 than in any previous year The volume of research papers does not appear to reflect this policy, however and a general account of work in progress will be found in the report and also in a paper by the Station's director, Mr R B Dawson (*J Roy Hort Soc*, **63**, 8, August 1938) A promising line of investigation concerns the use of potassium permanganate on lawns, to destroy moss and expel earthworms, further developments will be awaited with interest Supplies of seed of St Ives creeping red fescue, the first of a series of improved strains of lawn grasses, are now available to greenkeepers This strain has greater leafiness and density of growth than the existing varieties, it has good winter colour, and reasonable resistance to fungal disease Successful courses of instruction in the science and practice of greenkeeping have been prosecuted at the Station, and practical demonstration has been greatly improved by the establishment of a permanent exhibition of implements for the treatment of lawns

Timber Resources of the World

The small handbook entitled The Rationalization and Conservation of the Timber Resources of the World (The Technical Press, Ltd, London 2*s* 6*d* net), by Dr A Harold Unwin, is written mainly with reference to the amelioration of the Special Areas and general improvement of woodlands Dr Unwin puts forward a series of proposals and suggestions of a somewhat varying nature In the short period since the Great War, a number of organizations have come into being in connexion with forestry and timber utilization in Great Britain and the Empire To mention but three, the Forestry Commission, the Forest Products Research Laboratory at Princes Risborough and the Imperial Forestry Institute at Oxford The timber trade has also a considerable organization Dr Unwin wishes for a more rational care of trees and woodlands, especially in Great Britain, and for a better and organized utilization of the world's timber resources Until recently, Dr Unwin was conservator and head of the Forest Service in Cyprus, having previously served in Nigeria Although there is much in the handbook of interest the same cannot be said of the practicability of some of the proposals The list of trees given at the end requires considerable revision, and would have been more serviceable had it included the botanical names

Racial Studies in Italy

It is announced in the *Corriere della, Sera* of October 5 that racial doctrine is to be made part of the curriculum of Italian universities It is to be taught to students of natural science, medicine, and biology, as well as to students of philosophy, educational theory and literature This innovation is made under a decree of the Minister of Education, Signor Bottai A second course is to be devoted to study of the demographic problem Italy has been slow in following Germany in the adoption of racial doctrine, nor, as was shown by the report of the Italian men of science on the racial question, has the doctrine been adopted entirely in the form, nor with the enthusiasm, which it has aroused in the country of its origin The physical characters of the main element in the Italian population would naturally call for some modification, and account for the stress, which in Italy is laid on continuity of cultural history

Preservation of the Fauna of the Empire

The Society for the Preservation of the Fauna of the Empire has been accused (according to an editorial note, in the August number of its *Journal*) of talking and doing nothing, while game throughout the Empire is being ruthlessly destroyed The accusation is unjust The powers of a private society are in any event strictly limited, since game preservation lies with the official Government of the territory in question Nevertheless, the Society has investigated conditions in various parts of the Empire and has reported upon the steps which might usefully be taken for the safety of threatened members of the fauna always keeping in mind that it is no part of its aim to preserve animal life to the detriment of human industry or the natural development of mankind The Society does encourage talk about animal preservation, but surely one of the secrets of the success of any great cause is the efficient propaganda which spreads information and may eventually make the cause part of the nation's will

Agricultural Education in Jamaica

A pamphlet of 86 pages (*Bulletin* No 14, New Series, 1938) issued by the Department of Science and Agriculture of Jamaica indicates the thoroughness with which that Government Department organizes agricultural education in the Colony It summarizes the series of addresses, lectures and demonstrations given by experts during a special refresher course devised for the staff of instructors of the Jamaica Agricultural Society, and held throughout a week in January The course was a varied one dealing with aspects of farming which included insects of economic importance to stock maintenance, sugar production, tobacco growing, afforestation, exporting and marketing of produce, banking in relation to agriculture and other subjects The pamphlet shows that these aspects were treated with thoroughness from the Jamaican point of view, and the appreciation with which the course was received was indicated by an audience of as many as 150 at some of the sessions

BRITISH ASSOCIATION DISCUSSIONS

Soil Fertility and Agricultural Policy

SPEAKERS in the discussion in Section M (Agriculture) following the presidential address to the Section at Cambridge agreed that agriculture in Great Britain is declining and the land suffering The only possible approach to a stable and long term agricultural policy must be a national one directed not merely to the production of commodities but also to the maintenance and enhancement of soil fertility

In his presidential address on Ley Farming and a Long term Agricultural Policy Prof R G Stapledon stressed the need for maintaining a large and contented rural population with the greatest possible acreage of fertile and ploughable land managed so as to allow the utmost flexibility of production The vital need of Great Britain for an abundant supply of fresh food is threatened not merely by war danger but also by the effects of soil erosion and soil depletion in the countries on which we have come to rely for cheap food The possibility of producing sufficient amounts of fresh food ourselves is not compatible with our present superabundance of permanent grass We need a survey on the land to map the main types of farming and the facilities of individual farms in order to determine both our potential food production and the way our schemes for subsidizing commodities and planning marketing are affecting the fertility of the land

Prof Stapledon gave the following outline classification of farming systems (*a*) arable farming including a one year ley for hay and for maintaining soil fertility (*b*) alternate husbandry or ley farming with arable cropping alternating with leys of either two or three or four to eight years duration (*c*) nondescript farming in which the arable land and the grassland occupy separate parts of the farm and (*d*) permanent grass He criticized the last system on both general and technical grounds Even the poorest permanent grass retains some earning capacity but it does so at the cost of a low standard of management complete dependence on imported foodstuffs and great wastage of both manurial residues and potential fertility Again as a later speaker said Permanent pastures perpetuate parasites

The best grassland holds within itself an immense store of fertility which can be cashed only by ploughing and cropping and thereby preparing the land for still better grass The urgent need for lime which has been emphasized by increased milk production and by the slaughter of young animals can best be met by applying the lime when the land is under the plough On the poorest soils there is nothing to equal continued ploughing down of sod accompanied by lime and phosphate to build up fertility Prof Stapledon particularly recommended the use of contrasted types of ley in rotations—one or two years ley for hay and deep rooting residues, and four- to six years' ley for grazing leaving shallow rooting residues rich in clover Experimental work is needed to discover the best rotations for individual districts and especially to find means of establishing leys without undue risk on the heaviest soils and in the driest regions These problems and many others in agriculture are more likely to be solved by agronomical investigations than by scientific research Facilities for conducting field experiments should be enormously increased

The only solution for our derelict areas is to determine by a survey which fields must be ploughed up and then to devise means of supplying working capital and ensuring its correct expenditure From his experience in North Wales, Prof Stapledon favours the idea of loans with a working plan through a master borrower' with the necessary tractor and other equipment or through scheduling districts for a rehabilitation loan on an agreed plan He believes, too, that the advantages of a more balanced specialization would be secured by a system of 'share farming by which, for example, a mechanized wheat grower and a poultry farmer might operate over a number of neighbouring ley farms devoted mainly to milk

Dr W G Ogg stressed the necessity for checking the drift of poor arable land through inferior pasture to rough grazings and wastes which would ultimately require very difficult and costly reclamation He doubted whether private individuals, even with cheap long term credits, could undertake the reconditioning, and suggested that it would have to be done by the State or by some State aided corporation, working in much the same way as the Forestry Commission does on land which the private owner is unable to afforest When the land has been reconditioned, and buildings, fences and water supplies made satisfactory, the farms could be rented with a clause in the lease to require suitable manuring and cultivation Dr Ogg showed by films some of the work of the Macaulay Institute for Soil Research in the reclamation of peat in Lewis and in Lanarkshire Satisfactory hay, pasture and silage have been secured by installing long wooden box drains leading to open collecting ditches and by using a rotary cultivator drawn by a caterpillar tractor, and supplying a cheap source of lime and the necessary fertilizers The spongy fibrous peat from *Sphagnum* in the Lanarkshire experiment has proved more amenable to treatment than the slimy *Scirpus* peat of Lewis, though in the drier parts of Lewis pasture has been established without cultivation and with very little drainage by using fertilizer, grass seeds and clover cleanings The Lanarkshire experiment was undertaken for the Commissioner for Special Areas in Scotland, and it was estimated that full reclamation would cost about £20 per acre

In analysing the basis of soil fertility and crop rotation, Dr E M Crowther emphasized the importance of soil structure and plant cover The essential contrast is between periods of cultivation with rapid oxidation, leaching and degradation of structure, and restorative periods under a vegetational cover leading to granulation of the soil, the return of nutrients to the surface and the production of active colloidal organic matter Under extreme conditions it has generally been found necessary to restrict, either by prohibition or by compensation, the amount of grazing or the proportion of the land occupied by the most wasteful crops, notably the widely spaced row crops with frequent cultivations Under our more temperate conditions there is a need, especially at college farms, for long range experiments along the lines of recent Rothamsted and Woburn experiments on crop rotations, testing the restorative value of leys, lucerne and green manures and the residual value of straw used directly and in farmyard manure and composts The use of fertilizers could be made far more efficient by combining a co-ordinated series of field experiments with soil surveys and soil analyses Such series of experiments are carried out annually in their thousands in most of the other countries of northern Europe whilst soil analyses have been used by the million in mapping for advisory purposes

Introducing the discussion on the papers, Sir Daniel Hall said that extra livestock cannot compensate for decreasing crop production since they are merely the manufactured products of imported foodstuffs Remedial measures costing some £40,000,000 annually were intended to maintain the *status quo* of our farming, but are not succeeding Better farming needs a measure of control through the landowner and cannot come through financial stimulus alone The landowners of Great Britain are so hampered by legislation and the immediate returns are so problematical that the landowners have ceased to have much influence on the farming of their land Even though land nationalization may not become a matter of practical politics for decades he suggested that a body should be set up and subsidized by the State to purchase the second class and poorer land, and get it into order and farmed properly Such a form of State activity is as necessary to-day as the production of shells and aeroplanes for defence The State is constantly acquiring large quantities of land for these and similar purposes and 'it should also busy itself similarly for the purposes of peace and for improving its own personal estate If not, what is the alternative ?"

E M CROWTHER

Ecology and Afforestation

THE symposium at Cambridge on The Cultivation of British Hardwoods (Department of Forestry K*) and the papers on The Ecological Aspects of Afforestation (Section K (Botany) and Department of Forestry K*) brought out clearly one point of great practical and scientific importance. It is the need for distinguishing between woodland and non woodland environments.

Since it is the policy of the Government to add to the existing area of woodlands it follows that most of the new planting is carried out on soils which bear a kind of vegetation other than woodland and it is just on this class of soil and under the conditions associated with it that difficulties are experienced in the establishment of hardwoods. Many if not all the soils of Great Britain presumably once carried some kind of woodland but the land has been cleared and put to various uses or misuses. Most of it has been farmed and still is but at various times some of it has been allowed to run wild. This marginal land is commonly heavy clay or light sand and its abandonment is usually attributed to falling prices of major farm produce. Doubtless this is a main cause but it may well be questioned whether modern farming methods by destroying the physical and biological regime of the woodland soil have not been a potent contributory cause. Besides the farm land carved from the original forest there are the wide open spaces of heather peat or poor grassland to which the forest failed to return because of regeneration difficulties due in the main to grazing burning or the lack of parent trees. Under these conditions too the forest soil has been altered in fact the set of conditions associated with a complex biological unit and built up slowly by Nature has been destroyed or degraded from its woodland status.

The problem stated affords an excellent illustration how the larger light emanating from the study of plant communities in general can be usefully focused upon the practical problems of the forester. For to the ecologist the forest is not merely a collection of trees with a certain density and rate of growth it is also a community of organisms living together in a more or less intimate and intricate relationship. This forest biological unit is achieved only after much preparation in Nature during the sequence of changes separating the early stages of the plant succession from the later culminating generally, in the climate of Great Britain, in woodland. It thus becomes easier to understand why trees like oak and beech which normally appear late in the succession are difficult to establish on new ground for the conditions of microclimate and soil (including microflora and microfauna) under which they become established in Nature are widely different from those offered by marginal and waste land. Further it is well for the forester to realize that in planting he is not only planting to produce timber but he is also setting in train a whole series of processes culminating in the formation of a complex biological unit.

Conifers are less exacting than hardwoods and can be more readily established on land available for planting and Prof H M Steven in his paper on The Ecological Aspects of Afforestation in Hill Country touched on their use as pioneer crops. He said that although vegetation may be a safe guide in the selection of species which will readily become established it need not necessarily be correlated with the subsequent growth of the trees after they have formed canopy. Here one can assume that the forest so to speak takes charge and changes the environment so that the coniferous crops now being established may be looked on as catch crops ameliorating the conditions for more exacting species to follow. The same points emerged in Mr R Ross s account of the colonization by hawthorn of abandoned arable land in the heavy chalky boulder clay district of west Cambridgeshire under the hawthorn scrub the soil changes in the direction of a woodland soil in acquiring more humus and an open crumb structure.

A pioneer coniferous crop mostly of pines has been successfully established by the Forestry Commission in Breckland an area with climate transitional between oceanic and continental and much subject to spring frosts with open permeable soils incapable of holding much water against shortage during drought and with a chalk content which varies from soils with much through soils deficient in it to those completely devoid of it. The last type is extremely infertile. Dr A S Watt gave a summary of his work on the area and concluded that liability to frost shortage of water and plant nutrients are the critical factors capable of amelioration at least in part through normal sylvicultural procedure. By controlling the canopy the internal climate of the woodland is ameliorated and the less hardy species can be successfully reared by careful choice of species and by planting them in suitable proportions the water holding and base holding capacities of the soil can be appreciably altered through the control of the amount and more important still the kind of humus produced

In the subsequent discussion Sir Roy Robinson explained that the exigencies of the moment had largely determined the selection of conifers for planting and that it was likely that the next generation of the forest would in certain parts of Great Britain at least differ markedly in com position particularly by the use of more hardwoods This is welcome news and more followed For Sir Roy announced on behalf of the Forestry Commission the initiation of a programme of closer co operation between the forester and the scientific worker particularly the ecologist and offered to set aside quite considerable areas in selected forests for purposes of scientific study primarily for a periodic record of the changes in the vegetation But many scientific interests are involved and one may look for results fruitful to science generally as well as to the forester from this opportunity to study a forest in the making

Limestones as Eruptive Rocks

THE carbonate rocks especially limestones and dolomites are so well known as sedimentary or metamorphosed sedimentary rocks that there may be some surprise that petrologists of Section C (Geology) of the British Association spent the greater part of a day during the recent Cambridge meeting in discussing the origin of carbonate rocks associated with alkali rich intrusions

The occurrence of limestones in close association with alkali rich rocks such as nepheline syenites phonolites and related types has been observed with great frequency and it has commonly been assumed that the limestones where not clearly belonging to a sedimentary formation were relics of sedimentary limestones assimilated in depth by the igneous magmas

According to a widely accepted theory proposed by R A Daly in 1910 such assimilation of lime stone by sub alkaline magmas is the cause of the formation of the alkali rich igneous rocks

However so early as 1892 some limestones occurring in the form of dykes and cutting the volcanic rocks of the Kaiserstuhl in Baden were described by A Knop and three years later A G Hogböm described limestone dykes in a region of alkali rich intrusives on the island of Alno in Sweden Hogbòm also recorded calcite as a primary mineral in some rocks at Alno and there were other descriptions of primary calcite in alkali eruptive rocks from Canada and India In view of the readiness with which calcite dissociates on heating geologists were reluctant to accept it as a primary mineral or to believe in limestone intrusions, but during the last few years much fresh evidence of apparently intrusive carbonate rocks has been obtained

The most convincing new evidence comes again from Alnò where the rocks are now far better exposed than they were at the time of Hogbom s visits forty three years ago They have been studied thoroughly by Dr Harry von Eckermann, of Stockholm who opened the discussion at Cambridge A large area of alkali intrusives—nepheline syenites and ijolites—cuts the Pre cambrian gneisses and is probably late Jotnian in age Around the contact with the gneiss (which is altered) crystalline limestones appear and out side the neck of intrusive rocks there are calcitic and dolomitic dykes which are shown to be cone sheets dipping towards two deep central foci From the inclination of the cone sheets the focus of the calcite dykes can be shown to be at 1 2 km below the present surface and that for the dolo mitic sheets at 6–7 km The geology of the country near Alno is well known and von Eckermann regards it as certain that for hundreds of miles around and to great depths there is no trace of sedimentary limestone in the Archæan rocks of earlier age than the alkali intrusives All the evidence points to a magmatic origin for these limestones at Alno

Magmatic origin is also claimed by Dr F Dixey for the crystalline limestone associated with breccias filling remarkable vents of post Karroo age in Southern Nyasaland At one of the largest of these vents Chilwa Island limestone and orthoclase breccias occupy a roughly circular area 1½ miles across and form steep cliffs rising 1 400 ft above the level of Chilwa Lake Nine larger and seven smaller vents are known and at most of them the limestones are cut by small bodies or dykes of alkali rich rocks nepheline syenite ijolite phonolite or nephelinite The rocks surrounding the vents are altered and there are many resem blances with the rocks of Alnö As for the source of the limestone Dr Dixey finds that the small lenticles of limestone known to occur in the Base ment Complex of the district are altogether too small and infrequent to have supplied the lime stone for the great masses of the Chilwa vents and the conclusion that they are in some way magmatic seems unavoidable

Mr S I Tomkeieff had visited Fen in Norway where the rocks closely comparable with those at Alnö were described in a classic paper by W C Brögger in 1921 He has no doubt about the magmatic origin of the carbonate rocks in that district

Prof S J Shand claimed that the limestones at Alnö and Fen and at eight other localities which he listed had been or ultimately would be proved to be derived from sedimentary or metamorphosed sedimentary limestones He described two areas of alkali rich rocks—Haliburton Ontario and Sekukuniland Transvaal—where he regards it as demonstrable that carbonate rocks associated with nepheline syenite have been derived by the incorporation of sedimentary or metamorphic limestones by igneous magma

Prof C E Tilley admitted that the limestone syntexis theory is applicable in certain places to a limited extent and he believes that the limestone intrusions in the Haliburton and Bancroft areas present certain peculiarities differentiating them from the other occurrences but he claimed magmatic origin for every other example of limestone associated with alkali rich rocks in Prof Shand's list He mentioned especially Magnet Cove Arkansas and Palabora Transvaal and he added two new examples Iron Hill Colorado and Kabossero at the head of the White Sea

The claim for magmatic origin of some of these limestones seems to rest on good field evidence but it needs to be supported by a credible explanation of how magmatic limestones can be formed and why they are associated with alkali rich intrusions To this task Dr von Eckermann devoted the last half of his address He outlined the possible processes which might have effected the formation at the base of the Jotnian sheet intrusions of a nepheline syenite magma rich in potash carbon dioxide fluorine and chlorine and he traced the possible history of such a magma as it stoped its way upwards to a point at which the concentrated volatiles shattered the roof and more or less pure carbonates filled the conical fractures in the surrounding rock Mr Tomkeieff also was able to suggest a possible petrogenetic scheme for the rocks of Fen He regards carbon dioxide as probably originally present in many rock magmas but lost by most during consolidation Where it is retained it must have a profound effect on the course of differentiation While Dr Eckermann made no claim that the explanation he had put forward applied outside Fennoscandia Mr Campbell Smith referring to the rocks of the Chilwa Series of Southern Nyasaland said that there are so many resemblances between them and the rocks at Alno and Fen that processes which were active in Fennoscandia in the Archæan must have been operative at the Chilwa vents in post Karroo times He said that in Nyasaland the problem is to explain the close connexion between the formation of pure orthoclase rocks (remarkably rich in potash) their brecciation the alteration of the country rocks the supply of material for and the emplacement of the crystalline limestone and the subsequent intrusion of alkali rich rocks

When the results of Dr von Eckermann's work are published it may be found that all these closely related events will find their places in the scheme of differentiation of which during the discussion he gave a brief description but which lack of space here compels us to omit

---

Vibration in Engineering

FOR the past few years the council of the British Association in co operation with the various sections has selected a number of scientific topics which are of direct interest to the general public and by means of symposia or otherwise to which workers in the particular fields concerned have contributed general reviews of our present knowledge and the problems still to be solved have been arranged Among the subjects chosen for the Cambridge meeting was vibration a phenomenon which in this mechanical age is in daily evidence to every one of us and the importance of which is very great The engineer is concerned with its results upon the structure in which it occurs which in an aeroplane for example may be disastrous and in any event will have a deteriorating effect The ordinary person be he traveller in motor car train ship or aeroplane is more concerned with the discomfort (and even maybe injury to health) which accompanies continuous vibration From whichever point of view it is regarded therefore vibration is a phenomenon which everyone desires to see eliminated or reduced to a minimum

Any elastic structure when disturbed from rest and released will vibrate freely for some time in one of a number of possible modes the particular one resulting depending upon the restraints imposed on the structure and upon the method of disturbance The frequencies of these modes are called the natural frequencies of the system When a bridge or ship for example is subjected to a sudden load, it will vibrate in one of these natural modes, but the vibration will be rapidly damped out When a periodic disturbing force is applied to such a structure vibration will ensue of the same frequency as the disturbing force, the amplitude depending upon the magnitude of the force This type is termed 'forced' vibration When the frequency of the disturbing force is equal to that of one of the natural modes of vibration of the structure a state of resonance occurs, and, theoretically, for a completely undamped structure, the amplitude will become infinite Actually, the movement is restricted by the damping of the supports and in the material and by the fact that the restraints alter completely when the amplitude becomes large but nevertheless, very serious vibration may and does result in all types of engineering structures under such resonant conditions

In any motor car ship aeroplane or other self-propelled vehicle, there are several sources in the machinery from which periodic disturbing forces may arise, and therefore very few such structures are free from forced vibration of one form or another In order that the amplitude of this should be so small as to be unimportant to passengers, the engineer must do everything possible to balance the machinery so that the magnitude of the out of balance forces may be small If this cannot be achieved by such means a vibration damper may be used Such a device was described and shown in action at Cambridge by Prof C E Inglis in introducing the symposium on the subject in Section G (Engineering) It consists of a small spring supported mass, of about one per cent of the weight of the structure and attached to it, and tuned to vibrate at the same frequency Under such conditions it is capable of reducing the vibration of the main structure to very small amounts indeed Similar devices have been developed for eliminating torsional vibrations in engine shafts

The most serious cases of vibration whether considered from a structural or a comfort point of view, are those in which resonance occurs Under such conditions even a very small residual disturbing force may cause large amplitudes of vibration, and in a completed structure suffering from this type it is usually necessary to alter the frequency of the disturbing force and so destroy the resonance This however, cannot always be done without sacrifices in other directions As Dr F H Todd pointed out, when dealing with ship vibration, if the revolutions of the main engines have to be reduced by ten per cent to avoid resonance with a natural frequency of the hull, this entails, if no other changes are made, a loss of speed of ship of the same order To recover this loss, a new set of propellers will be necessary, and it is not then always a practical solution, since in certain types of engines, particularly oil engines, it is not permissible to increase the pressures in the cylinders in order to develop the original power at the lower revolutions One cannot usually destroy resonance in a ship by going to higher revolutions, since within the possibilities of a completed engine the margin will be small, and as soon as bad weather is encountered the revolutions will fall into the resonant range again

It is evident that the possibility of such resonant vibration should be considered in the early stages of any design in order that the frequencies of the engine forces should not coincide with any of the natural frequencies Fortunately, as Prof Inglis pointed out, vibration is one phenomenon in engineering which can be dealt with by precise mathematical methods and we can calculate the natural frequencies of many designs while they still exist only on paper, and so ensure an absence of resonant vibration in the completed structure Such calculations can be made for a ship for example, taking into account the variation in load and strength along the length of the hull girder A very important consideration in such a calculation appears to be the inclusion of the effect of the surrounding water This influences the vibration by its damping effect, which will restrain the amplitude at resonance, and also by the virtual inertia effect due to the loss of energy entailed by the movement imparted to the water underneath and alongside the hull as it vibrates The amount of this virtual inertia can be determined mathematically, and is equivalent to an addition to the hull weight of about its own magnitude for normal ships, and for a wide, shallow draft ship the increase of inertia may be three times the vessel's displacement These quantities seem large at first sight, but Dr Todd showed that the calculated frequencies so obtained for the primary vertical vibration agree remarkably well with the recorded natural frequencies for some sixteen vessels on which he has obtained their values experimentally

In aircraft, similar vibration troubles arise in the fuselage and air-screws In many cases these are due to forces originating in the engines, and as before special attention to the balancing and care in avoiding resonant speeds is essential In addition, vibration can be caused by aerodynamic forces Examples of such cases were given by Major B C Carter, including tail flutter, wing flutter and flutter of air-screw blades In certain conditions of flutter, instability may arise, and portions of the structure be torn away Knowledge on this branch has increased greatly of recent years, and enough is now known about it to avoid such disastrous effects Any new design of air screw is also subject to exhaustive tests to ensure that it is free from flutter before being used in machines.

In order to study vibration of aircraft in flight very delicate instruments are necessary, and some of those developed at the Royal Aircraft Establishment were described by Major Carter. One vibrograph designed there records the amplitude on a photographic film and can be operated by the pilot during flight by remote control, and yet is very compact and only weighs a little more than two pounds. To obtain records of air screw blade tip vibration in flight, a camera is secured to and rotated with the hub, the motion of the blade tip being recorded on a film by means of the relative movement of a small electric light bulb cemented to the tip of the blade. Other modern methods include the use of photo-electric cells, the variation of the resistance of a body under stress and cathode ray oscillographs. It is evident that all the latest developments of the electrical and physical sciences are being adopted in these instruments.

One aspect of the vibration problem touched upon by all three speakers at the symposium was the use of elastic mountings for prime movers, and this is a device which is being developed very rapidly, particularly in the design of motor vehicles. Such mountings bring with them their own problems, but we can look forward to a progressive improvement in comfort in all forms of transport by the successful elimination of vibration through their use. Much remains to be done in this way, but it was evident from this discussion at Cambridge that the engineering profession is fully alive to the necessity and is progressing rapidly in all its many and varied branches.

Incremental Permeability of Special Steels

THE importance now attached to the incremental permeability of silicon steel and of nickel iron alloys arises from the use of these materials for the cores of transformers and chokes in communication apparatus. Under these conditions the magnetization is due to a continuous steady current upon which a variation is imposed either by modulation or by separate coils carrying alternating currents. Generally the amplitude of the imposed wave is not great enough to reduce the steady magneto-motive force to zero, so that the value of the induction rises and falls as the resultant magneto-motive force changes, but it does not reverse. The calculation of the induced electromagnetic force in a secondary coil in these circumstances is fraught with peculiar difficulties.

Adopting the usual convention and indicating magnetic induction by B, magnetic force by H and permeability B/H by μ, then if the mean value of B is not high and its variation small, the mean ratio B/H over the change will approach the value of μ as measured and used for simple alternating currents. But as the mean value about which B varies gets nearer to the saturation region of the iron, and particularly when the imposed variation is large, not only does the mean value of μ fall rapidly but also its instantaneous value varies considerably. The consequences are (1) that the prediction of a secondary induced E.M.F. is difficult; (2) that if the imposed variation of H be sinusoidal the wave form of B will be distorted; (3) that if the imposed variation of B be sinusoidal the wave form of H will be distorted; (4) that losses associated with given variations in B and H become difficult to measure and very different from those in the same iron under simple alternating current conditions. Yet makers of communication apparatus must know what results they may expect from the material that they purchase, so that some method of specifying and of testing the quality of steel for these purposes is badly needed.

This was pointed out by Dr. J. G. A. Sims at a meeting of Section G (Engineering) of the British Association at Norwich (1935), and he added that the British Standards Institution specification for transformer steels (No. 601), which had been published that year, would not serve for these new purposes. Section G, recognizing the importance of the matter, asked Dr. Sims to ascertain what was being done both in England and abroad and to report at the Blackpool meeting in the following year. As a result, a questionnaire containing eleven questions was sent out from the University of Birmingham, and an analysis of the replies was presented at the British Association meeting of 1936, representatives of the British Standards Institution being present. On seven of the questions world opinion was sufficiently unanimous to enable Section G to ask that tests should be begun upon silicon steels based upon an alternating current method of test, sinusoidal variation of induction at 50 cycles per second and with samples in the form of a ring.

In February 1937 the British Standards Institution formed a committee to consider the drafting of a specification based upon these tests and the extension of such tests to cover the much wider conditions occurring in practice The experimental work has been proceeding at both the University of Birmingham and the Northampton Institute Clerkenwell London and substantial progress has been made by the British Standards Institution Committee At the Nottingham meeting of the British Association (1937) when papers embodying the results to date were read it became evident that methods of defining and measuring the harmonic content of a distorted wave were needed and that there were difficulties in connexion with symbols Two methods of measuring the wave distortion were given and the experiments by Greig and Parton proved that this factor could be determined either by a filter bridge or by an alternating current potentiometer

The papers presented at the Cambridge meeting of the British Association before a joint meeting of Section A (Mathematics and Physics) and Section G showed a great extension of the experimental work by the teams in Birmingham and London and in addition Mr D C Gall gave an account of the manner in which academic instruments could be adapted to commercial requirements while Mr C E Webb outlined the rapid advances that are being made in alloys suitable for transformers and communication apparatus

The subsequent discussion was remarkable for the comments by makers and users of the steels under test it is a pity that more time could not be allotted for valuable contributions of this kind which the British Association and perhaps the British Association alone can evoke In the matter of symbols and definitions little progress was made the only helpful remarks coming from Prof G W O Howe who showed that in Germany both definitions of distortion factor suggested by Sims and Greig were used rather indiscriminately with little inconvenience The official view of the British Standards Institution was expressed by Mr J F Stanley He emphasized the role of that Institution as a body holding a balance between research and utility and therefore bound to search for a practical specification He remarked upon the fact that the research work in this instance was unique in that it is in the hands of educational institutions and not commercial research organizations He welcomed as a guide the broad discussion at the British Association but held that actual decisions must be left to the Institution Committee Many references were made to the new materials mentioned by Mr Webb More than one speaker commented upon the amazingly high permeabilities which he had disclosed On the other hand doubt was expressed as to whether such values would be found under polarized conditions for Parton and Glazier have shown that there is an actual reversal of the usual order of permeability of annealed and unannealed specimens when they are polarized Again in connexion with the effect of impurities in alloys one speaker (Mr W Randall) said that atomic order has been found very important especially in the case of molybdenum and of chromium and that the direction of the crystal axes also must not be overlooked Others warned the investigators that results obtained on silicon steel would not apply to nickel iron alloys and as Mr Ronald Sankey reminded the meeting the new cold rolled silicon steels may call for special attention

Two general suggestions of great value emerged from the steel makers and users who were present The first stressed by Mr Ronald Sankey and Mr K Macfadyen was to the effect that tests suitable for quality control and acceptance—routine tests in fact—should be kept separate from tests devised to determine the exact properties of the materials This of course is bound up with the question of apparatus suitable for routine work in which connexion as an addition to Mr Gall s proposals both the disk magnetometer and the Ferrometer were mentioned It is one thing to deal with a few ounces in the laboratory quite another to deal with tests on 50 tons of stampings and no doubt the industrialists were right to direct attention to this question of perspective Dr F H Rayner of the National Physical Laboratory thinks that it might be advantageous to put forward a temporary specification that could be tried and revised after a year or so

The other suggestion was a plea that any specification should so far as possible be international Section G has from the first kept this in mind as is shown by the wide dissemination of the Birmingham questionnaire but the duty of seeing that British steel makers are not penalized in the world s markets is a new aspect of this question which the British Standards Institution must not neglect

The discussion very properly laid bare the great difficulties both academic and practical with which this subject bristles It is clear that progress is being made and nothing but good can result from such an open and free debate At the same time the whole development shows a section of the Association moving in a new and useful direction For not content with recording the advancement of its science for the benefit of the public it has pointed out to an industry a region in which scientific advance is needed Further with the friendly co operation of that industry it has initiated a movement which will help manufacturers to specify and to test the magnetic qualities of their most important raw material

Organic Chemistry of the Metals

A DISCUSSION on recent advances in the organic chemistry of the metals, which had special reference to the transitional metals was held in Section B (Chemistry) during the Cambridge meeting of the British Association It was opened by Dr F G Mann, who said that recent advances in the organic chemistry of the metals are so numerous and cover so wide a field that any attempt to deal comprehensively with them in the brief time available would become a mere catalogue of individual investigations The most important advance which in his opinion was the investigations (mainly by Hans Fischer and his co workers) into the structure and synthesis of the porphyrins, was however, too specialized and too complicated for suitable treatment on that occasion, he therefore limited his own contribution to an account of certain polynuclear metallic compounds since this work was largely carried out in Cambridge and its discussion which followed logically from Prof C S Gibson s presidential address to Section B involved certain questions of chemical linkage which are of fundamental and therefore general interest

It has been known for many years that when spongy platinum and phosphorus pentachloride are heated in a sealed tube, two compounds, of empirical formulæ $(PCl_3)_2PtCl_2$ and PCl_3PtCl_2 respectively are formed These compounds when treated with an aliphatic alcohol ROH give the corresponding ester derivatives $\{(RO)_3P\}_2PtCl_2$ and $(RO)_3PPtCl_2$ Molecular weight determinations on the latter compound show, however, that it has the molecular formula $[(RO)_3PPtCl_2]_2$, and Werner suggested in 1909 that the parent compound had the structure (I) or (II) Similar results have been obtained with the corresponding palladium derivatives

(I)

(II)

Decisive evidence for this bridged linkage of metallic atoms through acid radicals has, however only recently been obtained when its existence in gold compounds was proved by Gibson and Powell (cf the sectional presidential address) and in palladium compounds by Mann, Purdie and Wells

The non ionic derivatives of the tertiary phosphines and arsines with palladium dichloride, of general formulæ $[(R_3P)_2PdCl_2]$ and $[(R_3As)_2PdCl_2]$, were known to have the *trans* uniplanar configuration Mann and Purdie showed that these compounds in hot alcoholic solution readily react with ammonium palladochloride giving derivatives, for example, $[(R_3P)PdCl_2]_2$, similar to (I) and (II) These 'bimolecular' derivatives should theoretically exist in three

$$[(R_3P)_2PdCl_2] + (NH_4)_2[PdCl_4] = [(R_3P)PdCl_2]_2 + 2NH_4Cl$$

forms, the unsymmetrical form (III) and the *cis* and *trans* symmetrical forms (IV) and (V) In the crystalline state they occur in only one form which is the same in both the phosphine and arsine series since the corresponding members in the two series are isomorphous This form has been shown by Mann and Wells to be the *trans* symmetric form (V)

There is abundant evidence however, that these compounds in organic solvents give a tautomeric mixture of the three forms (III) (IV) and (V) This is shown partly by their anomalous dipole moments,

(III)

(IV)

(V)

which have been measured by Dr Finn at Oxford, and partly by their chemical reactions Thus strong evidence in favour of the unsymmetric form (III) is provided by αα dipyridyl (symbolized by dpy) which splits the phosphine compound thus

$$[(R_3P)_2PdCl_2PdCl_2] + dpy \quad [(R_3P)_2PdCl_2] + [dpy\ PdCl_2]$$

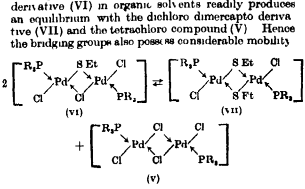
Moreover the dichloro oxalate which presumably has also the unsymmetric structure gives a similar reaction

$$[(R_3P)_2PdCl_2PdC_2O_4] + dpy \quad [(R_3P)_2PdCl_2] + [dpy\ PdC_2O_4]$$

On the other hand, a monacid base such as *p* toluidine (represented as B) splits the compound in its symmetric form

$$[(R_3P)ClPdCl_2PdCl(PR_3)] + 2B \quad 2[(R_3P)(B)PdCl_2]$$

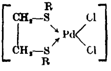
The formation of this equilibrium from the homogeneous crystalline compound shows that the unbridged groups in these molecules must readily interchange their positions This mobility is not however limited to the unbridged groups Chatt and Mann recently showed that the trichloro monomercapto derivative (VI) in organic solvents readily produces an equilibrium with the dichloro dimercapto derivative (VII) and the tetrachloro compound (V) Hence the bridging groups also possess considerable mobility



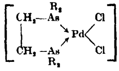
(VI) (VII) (V)

Prof N V Sidgwick had pointed out that the symmetric forms (IV) and (V) differ from the unsymmetric form (III) inasmuch as they possess the ring (VIII) and might be expected to have greater stability than the unsymmetric form (III) The chelated di sulphide and di arsine compounds (IX), (X) and (XI) have consequently been prepared by Chatt and Mann If these compounds reacted with ammonium pallado chloride, the resulting bridged compounds must have the unsymmetric structure of type (III) Actually no 'bridged' derivatives were obtained from these three compounds, and it appears therefore that the unsymmetric compounds are too unstable to exist in the solid state On the other hand, Mellor, Burrows and Morris prepared two isomeric cupro cupric compounds, of formula $[(R_3As)_3Cu_2Cl_2]$, and suggested that these isomerides have the constitutions (XII) and (XIII), the cuprous and the cupric complexes having the tetrahedral and the uniplanar configuration respectively The former compound possesses a ring structure electronically similar to that in (III), and decisive evidence for the structure of these isomerides would be of great interest Reference was also made to the cuprous and argentous compounds $[R_3As \rightarrow CuI]_4$ and $[R_3As \rightarrow AgI]_4$ investigated by Mann, Wells and Purdie

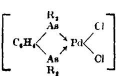
(VIII)



(IX)

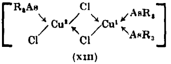


(X)



(XI)

(XII)



(XIII)

Prof L O Brockway pointed out that investigations of the structure of organic derivatives of the noble metals now afford definite information with regard to the number and length of the bonds by which the metallic atom is linked to other groups, as well as the characteristic inter bond angles, the number of such bonds is 2, 4, 5 or 6 in the compounds of various metals The 4 covalent metals in the copper and nickel groups have a planar configuration in the divalent state (for example, the above palladium compounds, the cupric and argentic picolinates, and the nickel, palladium and platinum aldoxime derivatives) and a tetrahedral configuration in other valency states (for example $[Cu(CH_3CSNH_2)_4]Cl$, $Ni(CO)_4$ $(CH_3)_3PtCl$) The 2 covalent metallic complexes have a linear configuration (for example, $[Ag(\overline{CN})_2]$) the 5 covalent a trigonal bipyramid (for example, $Fe(CO)_5$) and the 6 covalent an octahedral configuration He emphasized however, that the work of Mann and Wells on the bridged palladium compounds shows that the co ordinate and co valent links (as represented in the above formulæ) are identical in length and that it is impossible to make a clear distinction between these links in complex metallic compounds As an example of the variation of bond length with the number of bonds per atom, he cited the series $Ni(CO)_4$, $Co(NO)(CO)_3$, $Fe(NO)_2(CO)_2$ $Cr(CO)_6$ The metallic atoms in these compounds are isoelectronic, but whereas the observed bond length to carbon in the first three compounds is 1 82–1 84 A in the fourth compound it is 1 91 A

A very interesting example of the application of complex metallic compounds to the study of nuclear physics was given in a preliminary announcement by Dr B C Saunders Dr Goldhaber and he have used the non ionic cupric derivative of ethyl aceto acetate to effect the separation of the active isotope of copper ($^{64}_{29}Cu$) The copper aceto acetate is irradiated by slow neutrons and its activity measured it is then dissolved in chloroform and shaken with aqueous copper acetate Some of the active isotope is thus transferred to the aqueous solution, from which it is precipitated by zinc, and its activity is measured The chloroform layer gives copper aceto acetate of much reduced activity F G MANN

Recent Research in Seismology

UNDER the chairmanship of Dr C G Darwin in the morning, and of Mr R S Whipple in the afternoon of August 23, a symposium on seismology covering a very wide field of topics was held at Cambridge in Section A (Mathematics and Physical Sciences) of the British Association At the outset, a very warm tribute was paid by Dr F J W Whipple to the pioneer work of Dr C Davison, who was the secretary of the earth tremors committee in 1895, when Prof. John Milne returned to England from Japan The work of these and others has led on to the present work on the International Seismological Summary, now being carried on by Miss E F Bellamy and Mr J S Hughes There are now 439 observatories in the northern hemisphere and 59 in the southern hemisphere sending seismological readings to Oxford, from which it has been possible to locate 2,865 different epicentres between 1913 and 1935 It is hoped that more stations will be initiated in the southern hemisphere, especially in South America and South Africa

In pure seismology, the discussion was continued by Miss I Lehmann of Copenhagen, who described and explained the characteristic seismograms obtained on instruments at different epicentral distances, the differences being due to reflections and refractions of the various pulses in the interior of the earth The suggestion by the late Prof H H Turner of the occurrence of especially deep focus earthquakes had been confirmed by the work of Dr R Stoneley, Mr F J Scrase and others, and this led Dr H Jeffreys to suggest that the hypothesis of Barrell was probably correct when he attributed finite strength to the earth down to a depth of about 700 km Further, the work of Dr D W Phillips helps to explain the existence of aftershocks, in that it has been shown that rocks may possess several strengths according to the method of application and duration of the forces The intensive study of deep focus earthquakes is likely to lead to solutions of some difficult seismological problems, including the depth of the core, the nature of the 20° discontinuity, and the times of transmission of the transverse wave up to epicentral distances of about 25°

In continuation Dr R Stoneley showed that, as the result of considerable labour, Turner's readings of the *L* phase of earthquakes corresponding to 0 48 mm /degree could be identified with long Rayleigh waves, and that the readings corresponding to 0 41 mm /degree could be assigned to the arrival of long waves first theoretically predicted by Prof A E H Love The former are usually designated *LR* waves and the latter *LQ* waves It is suggested that the difference between these two types of waves is due to differences at the origin *LQ* and *LR* are well separated at distances greater than 50°

Of interest to pure seismology is the work of Prof J D Bernal, who concludes that there may be, at the pressures and temperatures existing at some depth within the earth, a denser and less compressible form of olivine, $(MgFe)_2SiO_4$, than occurs normally on the surface This would possibly explain the 20° discontinuity Crystallography should also be considered when discussing the structure of the earth's core

Interesting on account of its application to both pure and applied seismology is the work of Dr D W Phillips, who described experiments he has performed in compression, bending and torsion on coal measure sandstones siltstones, mudstones, shales and coals, and also on some samples of marble These experiments show up very clearly the imperfect elasticity of the rocks, which behave as perfectly elastic under stresses applied for a short time, but give hysteresis loops, possibly with complete recovery only after a very long time, when a stress is applied for a longer time An interesting phenomenon found is that a stress large enough to give irrecoverable deformation may at first give only continuous deformation and yet lead to fracture if it is maintained long enough Dr Jeffreys showed later how this may account for the occurrence of continuous folding and fracture in the same arch a common geological phenomenon The fracture would cause an earthquake

In the realm of applied seismology, Mr T F Gaskell described the method of working and the results of the work of Dr Bullard and himself The method is to fire a small amount of gelignite and record automatically the seismic waves set up, by means of geophones at 200 ft intervals up to 1,000 ft, recording the initial time of the shock by a radio signal From the resulting seismograms the shape of the palæozoic floor of part of eastern England has been determined, the process being facilitated by the fact that the wave velocities in the palæozoic rocks are high, whilst those in the chalk and overlying strata are low

Educational Significance of the Cinema and Wireless

A JOINT discussion at Cambridge on August 23 between Section J (Psychology) and Section L (Educational Science) on the cinema and wireless in education was opened by Mr R C Steele, who dealt mainly with broadcasting

Pointing out the remarkable growth in the use of broadcast methods since they were first introduced in schools fifteen years ago, especially in the last two years, Mr Steele referred to the difficulty of evaluating their effects He suggested that with dull or backward children the broadcast lesson is probably more effective in proportion to their ability than with the brighter pupils It also offers a change from ordinary routine, presenting new material in a new and vivid way, which appeals to the imagination He considers that with the backward child it is a further advantage that the broadcaster, though he may ask questions, does not expect answers, and the dull child may thus gain confidence instead of being made conscious of inferiority to others Mr Steele stressed the importance of personality and, discussing the use which could be made of broadcasting in education, suggested that where detail is of prime importance, as in a science lesson, the film is likely to be supreme Where perfection of detail is less important and immediacy is the first consideration, broadcasting and television may give the best results, and he predicted a great future for television in school teaching

Mr Steele's paper was supplemented by a paper by Miss L M Holt giving some statistical results of tests made with children who had been having wireless and ordinary lessons alternately, which were designed to determine the characteristic contributions of this new aid to teaching The spontaneous contrasting of the facts in their possession was slightly higher in essays based on wireless lessons than in essays based on oral lessons, while a fine perception of specific or significant detail also characterized the wireless essays, indicating a good grasp of the subject

Dr P B Ballard, discussing the effect of wireless and the cinema on the life of the school child, emphasized the experimental nature of the educational film as part of the school programme It cannot be assumed that the child always prefers a talking to a silent film There is direct evidence to the contrary, and for educational purposes the evidence indicates that the film should be short—for example, five to ten minutes—and unless the commentator speaks slowly and clearly and in simplified language appropriate to the audience, a silent film with printed captions is preferable Reference was made to the bad influence of the ordinary cinema on children, particularly through displaying life not as service and quiet happiness but as self indulgence and the mad pursuit of pleasure Dr Ballard was emphatic that ordinary broadcasting should not be allowed to curtail a child s necessary quota of sleep or to interfere with his homework

Though broadcasting as compared with the educational film is comparatively mature, both methods have certain common characteristics and drawbacks They are not complete educational units, there is no give and take between teacher and taught They belong to the passive side of school work rather than the active—the impressional rather than the expressional Both also have their affinity with mass instruction rather than with individual study The capital virtue of the film is that it enriches the pupil's experience, while that of the radio talk is that it can do for the teacher what he could not do for himself Dr S J F Philpott suggested that both methods may tend to diminish the gap between the dull and the brighter pupils

The closeness with which a crowded audience followed the discussion bore witness to the deep interest in the possibilities of this new technique, and also to the realization of the dangers which attend its abuse in adult life as well as in childhood and adolescence

Professionalism in the Modern World

IN a highly suggestive paper on Professionalism read before Section F (Economic Science and Statistics) at Cambridge on August 19, Mr T H Marshall reviewed the development of the professions and discussed their place and inference in society to day According to Herbert Spencer, the history of the professions can be traced back to primitive societies From the first they were non manual, and Mr Marshall pointed out that their second characteristic was that they were not commercial, an ethical distinction clearly stated by the Greeks Payment must not be the motive in professional work The third characteristic of professionalism, the association follows from the first two It serves to maintain the power of brain work to command the produce of manual labour, and it ensures that men who must not work in order to be paid are nevertheless paid enough to support them at the right social level The official aim of a professional association is the preservation of a high standard of efficiency among its members This is achieved by training and examining all candidates for admission and by obtaining privileges as against all non members, which may amount to a legal monopoly Such rights can only be claimed where the profession is based on a body of special knowledge or on a scientific technique which can be imparted in training colleges and tested by examinations The typical professional association is a body that controls the application of science to the service of society

In spite of this corporate responsibility to society, the professions are by tradition intensely individualistic, and the close personal relation of trust between the professional man and his client has proved an obstacle to the enlistment of the professions in the service of the State Under the growth of science, the evolution of capitalism and the advance of democracy towards the social service State not only have many new professions been developed but also the part played by personal character and tradition in the older professions has diminished Capitalism requires professional men to work for impersonal corporations and may make him an employee Democracy is leading the professional men to study the whole social background of the problems confronting him, and the professions are being transformed from strongholds of narrow individualism into most hopeful agencies for scientific social planning

Simultaneously Mr Marshall pointed out the antithesis between commerce and the professions has been greatly weakened While the professions have been enlisted in the service of trade the administration of trade is becoming professionalized The salaried employees of big businesses are like the professional man, neither capitalists nor wage earners Mr Marshall suggested that they might become merged into a homogeneous social group, working not for profit, but for economic security, and out of interest in the job, a group favouring rational planning in public life, and individual freedom in private life, a group opposed to war whether between nations or between classes There is much in common between professionalism in its modern form and some parts of the theory underlying Fascism Moreover if this new class is to be effective, either its tactics must be Fabian in the extreme or it must seek allies Mr Marshall suggested that the vital question is the attitude this new class is inclined to take up towards the conflict between capital and labour, or whether it is likely to evolve a system of its own differing from that advocated by either of the two contending parties

Research Co-ordination Committee

An account of the work carried out by the Research Co ordination Committee during the past year was given at a meeting of the Group held in Cambridge on August 22 The work included (1) a list of essential statistics, on which the views of bodies utilizing statistical data (Political and Economic Planning, Engineers' Study Group, New Fabian Research Bureau), the Institute of Statistics and several leading statisticians have been obtained, (2) co ordination of work on South Wales problems including a résumé of industrial proposals, bibliography on South Wales, report on land improvement, and on family budgets of employed and unemployed workers, (3) information on numerous societies and sources of information, which it is hoped will be published in the form of a directory of associations The Research Co ordination Committee has also been active in bringing together editors of scientific and other periodicals to consider co ordinating publications and has gathered material which is to be put before the new Division of the Social Relations of Science of the British Association

Safeguarding Unpublished Research

During the recent period of uncertainty in international relations, the Research Co ordination Committee approached several organizations having valuable unpublished data with the view of securing co operation for their safety in case of war The microfilm technique of duplication was considered, since it is relatively inexpensive (about 0 1*d* per page) when the necessary apparatus, which can be hired for a minimum period of one year, is available This could be arranged if a sufficient number of bodies co operate The response has been satisfactory, and others interested should communicate with the Hon Secretary, Research Co ordination Committee, 35 Gordon Square, London, W C 1

Memorandum on Smallpox

During the last three years, Great Britain has enjoyed comparative freedom from smallpox, and the Ministry of Health has therefore considered it appropriate to issue a memorandum in order to direct the attention of local authorities to the possibility which now exists of limiting the spread of smallpox by prompt and vigorous action as soon as it is reported to have appeared (Memo 215 (Med) London H M Stationery Office 2*d*) The memorandum contains an account of the incidence of, and mortality from, smallpox in England and Wales since 1901, and a summary of the procedure which should be adopted should the disease appear in a district

Suggested Science Museum for Cambridge

A large exhibition of historic scientific instruments and specimens was arranged under the auspices of the Cambridge Philosophical Society for the meeting of the British Association last August It was most gratifying to see the long series of instruments associated with the great masters of the Cavendish Laboratory—with Wollaston, Clerk Maxwell, J J Thomson, Rayleigh and Rutherford—but the older periods were also well illustrated by loans from the colleges At the final meeting of the General Committee in Cambridge, it was resolved that an expression of hope that the scheme for a permanent exhibition of historic scientific instruments in Cambridge would be brought to fruition, should be communicated to the University authorities, and this has been done

Electrified Omnibuses

Mr A E Wiseman, 21 Hanbury Road, Acton London W 3, writes stating that on boarding an omnibus recently, he felt a distinct electric shock on grasping the metal handrail with one foot on the step and the other on the pavement The effect was also observed by others, particularly on crisp mornings He suggests that the electricity may be caused by the friction of the tyres on the ground, which incidentally insulate the body of the bus It is of interest to note that this effect was described in a letter in Nature of June 29, 1929, p 981, by Sir Charles Boys, who observed it on a hot dry day and ascribed it to the scuffling of the tyres on the polished asphalt

A Naked-Eye Sunspot

A giant sunspot easily visible to the naked eye, is crossing the sun s disk in latitude 17° north from October 5 until 18, the time of central meridian passage being October 11 9 The area of this spot on October 6, corrected for foreshortening, was nearly 2,500 millionths of the sun s hemisphere and on October 8 its area measured 2,800 millionths, the measurements being made at Greenwich Observatory The spot on the latter date extended in solar longitude for about 125,000 miles Sunspots as large as this one are usually associated with terrestrial magnetic disturbances commencing about one day after the time of central meridian passage On October 7, a small magnetic storm was recorded at the Greenwich magnetic observatory at Abinger the disturbance reaching a maximum between 16^h and 20^h U T The ranges of the magnetic elements were in declination 51′ in horizontal force 200 γ, and in vertical force 260 γ It seems uncertain, however, whether this magnetic disturbance can be linked to the big sunspot, the most probable time of one related to the disturbed area of the sun containing this sunspot would be about October 12–13

Colonial Service Appointments

The following appointments in the Colonial Service have recently been made W D I Corby, agricultural officer, Nigeria, T N Greeves, agricultural officer, Nigeria, D G Jones, agricultural officer, Malaya, H T Measure, agricultural officer, Kenya, R J S Waddington, inspector of mines, Nigeria, D Luke, veterinary officer, Uganda, L D Branch, inspector of plants and produce, Gold Coast, C L Crosse, sleeping sickness control officer, Nigeria, J H C Hicks, sleeping sickness control officer, Nigeria; R Patterson, inspector of plants and produce, Gold Coast, B E V Parham (temporary assistant agricultural officer), agricultural officer, Fiji, J D Tallantire (agricultural officer, Nigeria), agricultural officer, Gambia (seconded), H E Hornby (director of veterinary services) director of tsetse research, Tanganyika Territory, D A Donald (temporary assistant agricultural officer), agricultural officer, Fiji, D L Foster (temporary assistant agricultural officer, Jamaica), junior agricultural instructor British Honduras, L W Harwood (temporary assistant agricultural officer), agricultural officer, Fiji

Biology in Education

UNDER the auspices of the Educational Advisory Board of the British Social Hygiene Council, a conference of principals and biology lecturers in training colleges will be held on October 22 at the British Medical Association House, Tavistock Square, London, W C 1 Prof J B S Haldane will speak on How to Make Biology Alive, and his remarks will be followed by discussion Dr Philippa Esdaile will speak on 'The Place of Field and Practical Work in the Biology Course" A discussion on The Concept of Human Biology will be opened by Mrs E J Hatfield and Dr H C Squires A selection of biological films will also be exhibited Further information can be obtained from the Secretary, Educational Advisory Board, British Social Hygiene Council, Tavistock House South, Tavistock Square, London, W C 1

Announcements

PROF B W HOLMAN assistant professor of mining in the Imperial College of Science and Technology has been awarded the Gold Medal of the National Bureau of Scientific and Industrial Research by the French Minister of Instruction and Fine Arts The award of this medal to a British subject is very unusual

DR ALBERT E QUINE, a medical officer of the Ministry of Health, has been appointed inspector of anatomy in England and Wales

SIR HENRY BASHFORD chief medical officer of the General Post Office, and Sir Kenneth Lee, chairman of Tootal Broadhurst Lee Co, Ltd, have been appointed to fill vacancies in the membership of the Industrial Health Research Board of the Medical Research Council

THE Council of the Iron and Steel Institute confirms that, in accordance with previous announcements, the joint Autumn Meeting of the Iron and Steel Institute and the Institute of Metals in New York and the tours in Canada and the United States of America have been cancelled The Autumn Meeting of the Iron and Steel Institute will be held at the Institution of Civil Engineers, Great George Street, Westminster, S W 1, on October 26, at 10 a m and at 2 30 p m The Institute of British Foundrymen has accepted an invitation for members to take part in the discussion on the third report of the Steel Castings Research Committee which will be presented during the afternoon session

THE Council of the Iron and Steel Institute has accepted an offer from Captain C A Ablett to present a prize of £50 for the best paper on steelworks engineering submitted to the Institute, written by a junior engineer employed in a British iron or steel works, irrespective of whether or not he is a member of the Institute Competing papers should be marked "Ablett Prize Paper' and sent to the Secretary of the Iron and Steel Institute, No 4 Grosvenor Gardens, London, S W 1, not later than January 31, 1939

THE fifth biennial conference of the National Council of Mental Hygiene will be held at the Central Hall, Westminster, on January 12–14, 1939 Further information can be obtained from the Secretary of the Council, 76 Chandos Street, Palmer Street, London S W 1

APPLICATIONS are invited for the Eunice Oakes research fellowship at the Hospital for Sick Children, Great Ormond Street, London, W C 1 Candidates must be less than thirty five years of age The salary will not be less than £750 per annum Further information can be had from the Secretary of the Hospital

THE Middlemore Prize for 1939 in medical and surgical ophthalmology, consisting of a cheque for £50 and an illuminated certificate, founded in 1880 by the late Mr Richard Middlemore of Birmingham, is offered by the British Medical Association for the best essay on the underlying causes of glaucoma with suggestions as to future research in clinics and laboratories The essay should be sent to the Secretary, B M A House, Tavistock Square, London, W C 1, before December 31, 1938

THE Council of the Ophthalmological Society of the United Kingdom has established a Treacher Collins prize of £100 to be awarded triennially for the best essay submitted upon a subject selected by the Council The subject for the first award is "Cerebrospinal Disease in Relation to the Optic Nerve' Essays should be sent before December 31, 1938, to the Hon Secretary, Ophthalmological Society of the United Kingdom, 5 Racquet Court, Fleet Street, E C 4

IT has been decided to form a medico-historical museum in Berlin after the model of the Wellcome Museum in London

AN unusually large number of cases of infantile paralysis in Holland this summer has caused German authorities in some districts to forbid Dutch children crossing the frontier

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 721.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Discovery of an Additional *Pithecanthropus* Skull

DURING the systematic search for fossil man in Java one of us (G. H. R. von K.) discovered, in 1937, in the Trinil formation of Sangiran (Central Java) an almost complete brain case of *Pithecanthropus*[1].

Amongst the material recently collected (July 1938) from the same area, a large fragment of an additional *Pithecanthropus* skull came to light. The fragment consists of the complete right parietal bone with the adjoining part of the left parietal bone and a small piece of the occipital bone. The three bones embrace in their original and entirely undisturbed arrangement a stone core composed of sandy tuft mixed with lapilli. The sagittal suture reaching from bregma to lambda is completely preserved. The right parietal bone also exhibits all the other sutures, only the sphenoidal angle being broken off. The coronal contour of the parietal bones is characterized by a very pronounced sagittal crest. Laterally there is a distinct depression reaching to the temporal line, from which the contour runs steadily outwards down to the squamous suture. The temporal line runs strikingly close to the sagittal suture.

These conditions entirely correspond to those which are characteristic of the Sinanthropus skulls. The pronounced flattening of the cap so specific for the two *Pithecanthropus* skulls known hitherto, is completely missing in the case of this new *Pithecanthropus* skull. On the other hand, this skull has the following peculiarities in common with both *Sinanthropus* and *Pithecanthropus* skulls: the lowness of the entire cap and the position of the greatest breadth, the latter having undoubtedly been situated above the origin of the zygomatic arch, as is the case with all *Sinanthropus* and *Pithecanthropus* skulls.

According to the state of the sutures the new skull belongs to a juvenile individual, in spite of the fact that the parietal bones show a thickness of more than 10 mm. near the bregma, and that the temporal line is well developed. The region of the occipital torus is preserved only to a very small extent, revealing only a faint swelling, apparently in correspondence with the age of the individual.

All the new *Pithecanthropus* finds demonstrate how important and promising it is to search for fossil man in Java, and to continue the work which has been made possible thanks to the generous support of the Carnegie Institution of Washington, D.C.

Two Stellar Systems of a New Kind

SOME months ago an extremely faint, widely extended stellar system in the constellation Sculptor was reported from the Harvard Observatory[1]. In many respects it appeared to be unlike any known stellar organization. The finding more recently of a similar system in Fornax, on photographs made with the telescopes at the southern station of the Observatory, suggests that a description of these objects may be of general interest.

The two objects are separated in the sky by a little more than 20° and both are in the south galactic polar cap[2]. The following tabulation, in which some of the quantities are clearly provisional, compares the two systems:

	Sculptor Cluster	Fornax Cluster
Right Ascension	0h 57.8m	2h 37m
Declination	34° 2.5	34° 4
Galactic latitude	−83	64.5°
Angular diameter	80	60 +
Total magnitude	9.0	9.5
Magnitude of brightest stars	1[illegible] 8	18.0

The distribution of stars is very similar in the two systems. There are no irregular nebulosities, no clumping of stellar images, no sharp or bright nuclei—only smooth and essentially symmetrical concentration to the centre with approximately 10,000 stars to magnitude 19.5. In uniformity and radial symmetry they resemble globular star clusters.

The occurrence within the areas covered by the clusters of numerous faint external galaxies of the usual types and abundance, shows that space absorption within the clusters is negligible and also permits the close comparison of their members with faint spheroidal galaxies. It is thus determined that these two systems are not supergalaxies (rich groups of galaxies) but are composed of stars.

The distances and linear dimensions could be readily determined if we knew the absolute magnitudes of the brightest stars. Colours and spectra may be procured eventually and assist in evaluating the luminosities; but at present we hope to find the distances through the discovery and measurement of Cepheid variables among the stars of magnitude 19.5 and brighter. Appropriate plates are being taken with the 60-in. reflector at Bloemfontein.

It is probable that the resemblance to globular clusters also holds for the distribution of absolute magnitudes and that the distance modulus, $m-M = 5(\log d - 1)$, for these two objects is not greater than 19.5. The corresponding distance of eighty kiloparsecs implies that they are of galactic dimensions and places them well within our local supergalaxy, three times the distance of the Magellanic Clouds and but a third of the distance to the Andromeda

Nebula At the distance of the Andromeda system these objects would, in fact, have long escaped discovery There may be several others in the local group of galaxies, such objects may be of frequent occurrence in intergalactic space and of much significance both in the census and the genealogy of sidereal systems

The new objects have some properties in common with globular clusters, others with spheroidal galaxies, and still others (nearness and complete resolution into stars) with the Magellanic Clouds If intermediate forms connecting them with one of these standard types were found, a correct interpretation would be facilitated

Within the large area covered by the Virgo super galaxy (distance two to three megaparsecs) is a number of seventeenth magnitude objects which are of low surface brightness and about one minute of arc in diameter, they are possibly clusters of the Sculptor Fornax type, associated in this super system with the two hundred or so typical galaxies that have magnitudes from 11 0 to 13 5 Details of the examination of this possibility will be reported elsewhere

Nature of Extensive Cosmic Ray Showers

THE counter experiments of Auger, Maze and Grivet Meyer[1], and those of Kolhörster, Matthes and Weber[2], indicate the existence of very large cosmic ray showers, extending over an area of many square metres, and consisting of several thousand particles In order to obtain information about the constituents of these showers, a cloud chamber with a 2 cm lead plate across its centre, situated in a room with a light roof, has been used in a magnetic field of 800 gauss The chamber was controlled by the five fold coincidences of counters distributed so that the outer counters were separated by 5 metres With this counter arrangement the chamber took, on the average, 0 2 photographs per hour

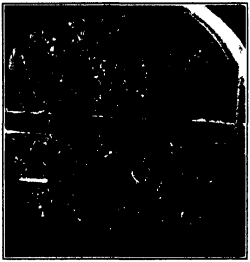
The twenty two successful photographs obtained show in all, about 250 incoming tracks, all of which can be interpreted as electron tracks Some of them produce small showers in a 2 cm lead plate in the chamber, and there is no indication of the presence of particles other than electrons One of the photographs obtained is reproduced herewith This is a part of the large shower which caused the five fold coincidence in counters separated by 5 m The photograph shows a typical cascade process, several particles, apparently energetic electrons, enter the lead plate and produce at least seven centres of multiplication

According to these photographs, it seems very likely that, if penetrating particles are present, they constitute only a small fraction of the shower particles, and are certainly insufficient in number to account for the penetration found by Auger, Maze and Grivet Meyer It is thus possible that the large air showers are in fact ordinary cascade showers A similar conclusion for the narrow air showers has been reached by one of us[3]

The distribution of the numbers of incoming tracks over the individual photographs is as follows

					Total
No of photographs	11	9	9	4	33
No of incoming tracks	0	1	2 10	>10	250 above the plate 300 below the plate

The average number of tracks per photograph given by the number in the above table is 8 It can easily be shown, however, that in order to calculate the mean density of tracks, this number must be reduced to about 5, because of the selective effect of the counter arrangement The area of collection for the chamber can be taken as the area of the lead plate in the chamber, which is 75 sq cm The mean density of tracks is then 700 per square metre This value is about twenty times that estimated by Auger, Maze and Grivet Meyer[1] from counter observations The discrepancy, however can be explained as follows



CLOUD CHAMBER PHOTOGRAPH OF AN EXTENSIVE COSMIC RAY SHOWER IN A MAGNETIC FIELD OF 800 GAUSS

A counter discharge takes place regardless of the actual number of particles passing simultaneously through the counter provided there is at least one Thus with counter observations it is not possible to differentiate between the passage of one or more than one particle, incident simultaneously on the counter Therefore the average number of particles incident on a counter can only be estimated by assuming a certain distribution law The calculations of Auger, Maze and Grivet Meyer assume inherently a Poisson distribution, that is, statistical fluctuation of the number of simultaneous tracks per unit area But since the average number of tracks per photograph is 5 the probability of finding due to statistical fluctuation, 150 incoming tracks on a single photograph (as has been observed once) is about 10^{-30} and is thus negligible Hence it may be seen from the data in the table above that the distribution of the numbers of tracks on individual photographs differs widely from a Poisson distribution The comparatively low density estimated from the counter experiments can then be understood as due to the assumption of only statistical fluctuations

Auger, Maze, and Grivet-Meyer found that one eighth of the shower particles penetrate more than 10 cm of lead Assuming these particles are electrons, the cascade theory shows that their energy must be greater than 5×10^{10} e v If we assume an area of 400 square metres for some of the showers, then *according to our new estimate of the mean density* of shower particles, some of the showers contain 30,000 particles ($\frac{1}{8} \times 400 \times 700 = 35,000$) of this energy The total energy of these particles would amount to nearly 2×10^{15} e v and the total energy of the whole shower taking into account also the particles of lower energy, would be still higher, perhaps as much as 10^{16} electron volts

Magnetic Anisotropies and the Valencies of Paramagnetic Atoms in Crystals

Studies on the magnetic anisotropies of paramagnetic crystals are of interest because of the variety of information one can obtain from them under favourable conditions, on such widely different topics as (1) the magnitude and the asymmetry of the internal electric field acting on the paramagnetic ion in the crystal, (2) the geometry of distribution of the negatively charged atoms immediately surrounding the paramagnetic ion, and hence the co-ordination number of the ion, (3) the magnitude of the Stark separation of the energy levels of the ion in the above field (in the special case when the paramagnetic ion in the crystal is in the *S* state, the Stark separation of its levels is naturally feeble, and it plays an important part in determining the thermal behaviour of the crystal at very low temperatures, in the neighbourhood of 0·1° K), (4) the strength of coupling between the orbital and the spin angular momenta of the electrons in the incomplete shell of the ion, etc In some recent papers[1] we have dealt with these various aspects of paramagnetic studies on single crystals In the present note we wish to direct attention to another useful application, namely, to questions concerning the valency of the paramagnetic atom in the crystal

We shall take, for example, the well known crystal manganite, the chemical composition of which corresponds to that of hydrated hemitrioxide of manganese On the basis of the available chemical evidence, the manganese in the compound is sometimes regarded as trivalent, corresponding to the formula,  $Mn{=}O(OH)$, and sometimes as half divalent and half tetravalent, corresponding to the formula,  A measurement of the magnetic anisotropy of the crystal should enable us to decide readily between these two alternatives The Mn^{++} ion is in the *S*-state (^6S), and should therefore be almost isotropic The Mn^{++++} ion, which is in the ^4F state, and resembles Cr^{+++}, should also have very little anisotropy On the other hand, the Mn^{+++} ion, the ground state of which is ^5D, should have a relatively large anisotropy in the asymmetric crystalline field A measurement of the anisotropy of the crystal, that is, the difference between its maximum and minimum susceptibilities to find whether it is of the same order of magnitude as in manganous and chromic salts namely 10^{-5} per gram atom of manganese at room temperature or is very much greater, will therefore decide whether the manganese atoms in the crystal are half of them divalent and the other half tetravalent or all of them trivalent

The crystal is monoclinic, and at 31° C its maximum anisotropy, namely, $\chi_c - \chi_a$ is found to be $4{\cdot}0 \times 10^{-6}$ per gram atom of manganese which shows that the manganese atoms in the crystal cannot be trivalent

The mean susceptibility of the crystal does not give us similar information The susceptibility of Mn^{+++} lies almost midway between those of Mn^{++} and Mn^{++++} and further the exchange interaction between the spin moments of Mn which should be large in this crystal owing to the large concentration of manganese affects the mean susceptibility considerably and to an uncertain extent whereas its influence on the anisotropy is almost nothing

Relativistic Motion of a Radiating Mass

In 1926, Prof F W Brown[1] raised the question whether the usual equation

$$m\frac{dv}{dt} = F \tag{1}$$

is rigorously true for a radiating star and in a letter to Nature, Sir Joseph Larmor has advanced from considerations of momentum that (1) is true

The motion of a radiating star, according to general relativity, does not seem to have been discussed in any of the standard treatises on the subject Granted that a non-radiating small mass describes *approximately*[2] a geodesic in the space-time field, the question is whether a radiating small mass also does the same just as, in classical mechanics, equation (1) holds good whether a mass radiates or not To settle this question we may write the equation of conservation of momentum, for the particle and the outgoing radiation, as the former traces its world line as

$$(mv^\mu)_{,\nu}v^\nu + \lambda v^\mu = 0 \tag{2}$$

in the usual tensor notation Hence

$$v_\mu(mv^\mu)_{,\nu}v^\nu + \lambda v_\mu v^\mu = 0$$

and, as $v_\mu v^\mu = 1$ it follows that

$$\frac{dm}{ds} + \lambda = 0 \tag{3}$$

substituting for λ in (2)

$$(mv^\mu)_{,\nu}v^\nu - \frac{dm}{ds}v^\mu = 0,$$

or

$$m\left(\frac{d^2v^\mu}{ds^2} + \Gamma^\mu_{\alpha\beta}v^\alpha v^\beta\right) = 0 \tag{4}$$

It is clear, therefore that a radiating small mass will also trace a geodesic

Another point[3] arises here which is of considerable theoretical interest For a non radiating mass equation (3) gives a constant m and the equation of conservation of momentum (2) thus splits up into the two

$$(i)\ \frac{dm}{ds}\quad 0, \qquad (ii)\ m(v^{\mu})_{\nu}v^{\nu} = 0 \qquad (5)$$

The corresponding classical equation of conservation of momentum does not imply the constancy of inertial mass as in (5i) and Mach had to supplement therefore the Newtonian laws by his theory of the inertial mass determined by the ponderable bodies of the universe

Infra-Red Absorption Spectrum of Sulphur Trioxide

The infra red absorption spectrum of gaseous and liquid sulphur trioxide has been determined by us, in the laboratory for physical research at the Sorbonne, in the region extending from 7μ to 14μ, with the help of the self registering rock salt infra red absorption spectrometer developed and described by Lambert and Lecomte[1]

In the final experiments, the absorption of the vapour at ordinary temperature was measured in an atmosphere of air in a tube of about 10 cm length—closed at both ends by plates of rock salt—forming part of an all glass apparatus possessing a reservoir filled with liquid sulphur trioxide, separated from the absorption tube by a glass wall which was broken immediately before the beginning of the measurements The apparatus was filled at Amsterdam by the technique developed by Smits Owing to a small quantity of water vapour present in the air, some fog was sometimes formed, but in such a small concentration that it did not give any trouble It is of great importance, but not easy, to avoid this formation of fog, which causes a rapid attack on the plates of rock salt Some preliminary experiments on the absorption of concentrated sulphuric acid in a layer of some microns thickness, between plates of fluorite, have shown that its absorption is very weak

For the vapour two infra red absorption bands were found, at 8 9 μ and at 7 5 μ, with the latter the stronger, corresponding with frequencies of about 1120 and 1330 cm^{-1} The Raman spectrum of gaseous sulphur trioxide shows with certainty only a frequency shift of 1069 cm^{-1}, while from experiments with the liquid at different temperatures and mixed with sulphur dioxide, the vibrational frequencies 531, 1068 and 1389 (double, in reality 1379 and 1404) for the simple molecule in the *liquid* may be inferred[2]

The complete absence of the intensive Raman shift 1068 in the infra red absorption in the vapour proves that the *free* molecule of SO_3 has a plane, practically symmetrical configuration[2] For such a molecule the symmetrical pulsatory vibration is not combined with a change in the electric moment of the molecule, so that in infra red absorption it is inactive

The number of fundamental modes of vibration of such a molecule amounts to four, probably corresponding with frequencies of about 530 and 560 (symmetrical and anti symmetrical deformation vibration respectively)—the latter inferred from the absorption band at 1120 cm^{-1} supposing it to be a first harmonic—and further, 1069 and 1330 (Owing to the much larger mass of the sulphur atom in SO_3, compared with the central atoms in the related groups CO_3'' and NO_3', the frequency of the vibration (560) whereby the central atom moves fairly strongly perpendicular to the plane of the O atoms, may be expected to be considerably smaller for SO_3, than for the groups mentioned, where 870 835 respectively have been found)

For the liquid, several absorption bands corresponding with frequencies (in cm^{-1}) of about 795 (12 6 μ), 860 (11 6 μ), 940 (10 6 μ weak) 1065 (9 4 μ strong) 1205 (8 3 μ, moderately strong) 1330 (7 5 μ, moderately strong) have been found without doubt belonging to different kinds of molecules present in this partially polymerized liquid[3] The strong appearance of the frequency 1065 in absorption in the *liquid* proves that in this state the single molecule SO_3 is considerably deformed from the plane symmetrical configuration it possesses in the vapour state

No sign of absorption in the neighbourhood of 1390 cm^{-1} (7 2 μ) has been found in the vapour or in the liquid

It is a curious fact that the absorption bands at 12 6 μ and 11 6 μ are in their intensity dependent on the circumstances of the experiments For example in a mixture of sulphur trioxide with about the same volume of carbon disulphide the intensity of the band at 12 6 μ diminishes considerably, while that of the other increases

Our hearty thanks are due to Prof A Cotton for his hospitality and to Prof A Smits for permission to construct the apparatus at Amsterdam

CH Bands in the Night Sky Spectrum

So long ago as 1934, we observed in the night sky spectrum, radiations characteristic of the nuclei of the comets, at about λλ 4300 and 4050 A[1] Their origin was then unknown The recent identification[2] of cometary radiations near λ 4300 with a band of the CH molecule induced us to search systematically for the CH bands in the sky spectrum For this purpose we used unpublished tables of wave lengths measured by Gauzit in the ultra violet and by Cabannes and Dufay in the blue and violet regions of the visible spectrum

Band λ 4300 The dispersion of the spectrograph is too small to allow us to find in the sky spectrum all the details observed by Dufay in cometary spectra Nevertheless, the correspondence between the sky radiations and the first rotational lines of each branch of the band is satisfactory We find in the sky the $R(3)$, $R(2)$ and $R(1)$ lines at λλ 4291, 4295 and 4299–4303, a stronger emission at λ 4312 5 can be identified with the two Q branches, we find $P(3)$ and $P(4)$ at about λ 4330, $P(5)$ at λ 4338

When we observe the spectrum of the sky near the horizon, the strong Vegard Kaplan band of nitrogen at 4316, degraded towards the red, hides the last two CH lines, but, at the zenith, while the whole Vegard Kaplan system weakens, these lines become very visible therefore there is something more in this spectral region than a Vegard Kaplan band

Since the intensity of the CH band does not obviously vary from the zenith to the horizon, it is not impossible that the CH molecules are outside the atmosphere and that a part of the night sky luminescence has an interplanetary or an interstellar origin It is interesting to recall that Swings has already proposed to identify the λ 4300 interstellar line, observed as an absorption line in stellar spectra with the $R(1)$ line of interstellar CH molecules[3]

Group of lines near λ 4050 These radiations of cometary nuclei occur also in the sky Cabannes and Dufay have shown that the lines of the 4050 and 4300 groups correspond to each other with a constant difference of frequency[4], which is about 1500 cm^{-1} In agreement with Baldet s observations, we cannot therefore identify the 4050 band of cometary nuclei and of the night sky with the weak Raffety band which, according to Grenat[5], is similar to the 3900 band It is possible that the group at λ 4050 represents a new CH band similar to the 4300 band

Band λ 3900 The 3800–3900 region is one of the least known in the spectrum of the sky Flint prisms are not transparent enough while quartz prisms do not give sufficient dispersion On the other hand, the 3889 Vegard Kaplan band coincides with the Q branches of CH The P branch only appears distinctly, the $P(2)$ lines at λ 3897 and the $P(3)$ lines at λ 3902

Band λ 3143 The very prominent maximum of this band is found in the sky at λ 3144 We have observed also the weaker maximum at λ 3157 No other origin has been suggested for these two sky radiations

Hence we conclude that the known CH bands probably exist in the spectrum of the night sky The radiations near λ 4050 form perhaps a new band similar to the 4300 band and certainly distinct from the Raffety band The emission occurs at a very high altitude or even outside the atmosphere We intend to compare again the intensities at the zenith and near the horizon in order to decide whether the emission of the bands that we attribute for the present to CH molecules is or is not connected with the earth s atmosphere

Fatty Acids from Yeast as Respiratory Factors

A NUMBER of papers[1] from this laboratory have reported the preparation from yeast and malt combings of fractions which stimulate the respiration of yeast and of animal tissues, particularly of skin A study of these fractions appears to indicate the existence of a multiplicity of respiratory factors The fractions studied thus far have been water soluble and thermostable They have all contained nitrogen and phosphorus but the fractions have been manifestly impure and it has been difficult to correlate the respiratory activity with chemical properties except to indicate that protein probably plays no part On the other hand it has been possible to correlate the proliferation promoting activity of preparations from yeast with nucleic acid like materials containing guanine, adenine, phosphorus and pentoses and having a maximum in ultra violet absorption[2] at 2600 A

We have now found that the steam distillation of a crude concentrate prepared by extracting yeast with aqueous alcohol yields about 0 05 per cent (based on the yeast) of a light coloured water insoluble substance having an indefinite melting point near room temperature and an unpleasant odour suggestive of isovaleric acid It does not contain nitrogen or phosphorus It is soluble in alcohol, ether, benzene, and alkali It has an iodine number of 5 5 by the Hanus method The high neutralization equivalent of about 295 is probably accounted for by the presence of contaminating fat soluble materials From the steam distillate can be obtained a nearly colourless potassium salt which is unmelted at 300° C but darkens at 210° and dissolves in water to form an alkaline solution The material gives a negative Liebermann Burchard reaction These properties point to a mixture containing saturated fatty acids

The material causes as much as a 350 per cent increase in oxygen uptake of a yeast suspension in concentrations of 0 5 mgm per c c, but higher concentrations are less effective and 10 mgm per c c is inhibitory In nearly all concentrations, the material is markedly inhibitory to the respiration of rat skin, although in low concentrations (1 mgm per c c) a slight stimulation is observed This behaviour is duplicated qualitatively by pure saturated fatty acids such as capric and undecanoic Thus the respiratory activity of the distillate appears to be related to its fatty acid content

The steam distillate, in proper concentrations, markedly stimulates the growth of epithelium in tissue cultures In the concentrations thus far investigated, the material appears to be inhibitory to yeast growth and fermentation

A detailed account of this work will appear later

Blood Ammonia and the Deaminases of Adenosine and Adenylic Acid

THE characteristic value of the general blood ammonia in man was shown to be either zero or below the analytical level[1] This has been confirmed for the rabbit and by H Kropowski for the dog, using the technique of this laboratory[2]

After shedding the ammonia develops from three sources The first or alpha ammonia (about 40 γ ammonia N/100 ml) forms immediately after shedding whether the pH of the blood be maintained or not, but does not form in the presence of carbon dioxide The amino compound involved may be adenosine protected by carbon dioxide (though the complex formation does not appear to be readily reversible) and deriving in turn from one or other of the adenylic acids Plasma has been shown to deaminate adenosine with great specificity leaving unattacked more than fifty other substances of biological significance and with amino or volatile amine groups This plasma deamination of adenosine and its great specificity was shown by one of us[3] prior to the communication of Drury *et al* to the Physiological Society in January 1937

The second or beta formation (about 1 mgm N/100 ml in the rabbit) comes from adenylpyrophosphate in the red corpuscles, breaking down mainly through the following stages adenylpyrophosphate → adenyldiphosphate + 1 phosphate → adenosine + 2 phosphate → inosine + 3 phosphate + ammonia (The phasic formation of ammonia previously reported[4] appears to be associated with the re esterification of adenylic acid) Adenylpyrophosphate disappears practically quantitatively in rabbit blood with the appearance of free ammonia The chief reason for supposing the final stages is that muscle adenylic acid in *high* concentration is freely deaminated by laked red corpuscles and vegetable adenylic acid also, but only at a small fraction of this rate As the concentrations of the acids are diminished so also is the deamination rate, but to a lesser degree for vegetable adenylic acid At a concentration of 0 05 per cent of the nucleotide they are deaminated at about the same rate This can be interpreted satisfactorily only on the basis of an initial dephosphation—at the low concentrations—followed by a deamination of the formed adenosine

The third or gamma ammonia (about 100—200 γ N/100 ml for man, and a mean of about 350 γ N/100 ml for the rabbit, judging from the twenty four hours formation) appears to derive largely if not entirely from vegetable adenylic acid, this being first dephosphated and then deaminated The following evidence exists for this supposition

(1) Vegetable adenylic acid is deaminated at the required rate, muscle adenylic acid and adenylpyrophosphate being excluded by the fact that the action of striped muscle extract has no effect in raising the plasma ammonia

(2) The rate of the gamma ammonia formation in plasma plotted against the pH shows two peaks, one in the region of 6 8 and the other at about 8 6 This double peak is characteristic of a phosphatase action signifying a preliminary dephosphation When vegetable adenylic acid is added to plasma, the extra ammonia formed after 24 hours shows a similar double peak and in the same position

(3) A large number of other possibilities has been excluded , for example, guanylic acid, guanosine, cytydylic, cytidine, etc , but not the adenyl compounds of desoxyribose, which remain as possible but unlikely precursors

Concerning the adenylic acid and adenosine deaminases of blood and tissues, it may be noted that adenylic acid in laked blood (and five other tissues similarly examined) is deaminated in proportion to its concentration beyond a certain critical value of 0 1–0 2 per cent of the nucleotide The activity of the deaminase also per unit volume of blood increases markedly with the dilution On the other hand, the ferment in striped muscle (about forty times greater in the mean than that of any other tissue) acts independently of the substrate concentration The indication is that the ferment in the red corpuscle and other tissues—except voluntary muscle—is reversibly bound to some inhibiting substance, which may be described as a protector substance for adenylic acid Comparative values of the adenosine and adenylic acid deaminases (adenylic acid in 1 per cent concentration) were studied in thirty six tissues of the rabbit With regard to the adenosine deaminase, it is a curious fact that the *appendix showed the highest concentration in the body*, having a mean value of 55 6 units of enzyme concentration (the unit being γ N/minute/gm tissue) compared with about 6–8 for whole blood, ileum and cæcum The values for duodenum and jejunum were also high but not so high as the appendix Of the eleven types of glandular tissue studied it is noteworthy that the liver came second lowest with 3 7 units (it contained the lowest amount of adenylic deaminase, namely, 2 2 units) The muscle group contained the least amounts of adenosine deaminase, the muscle of the auricle being highest in the series with 6 8 units and voluntary muscle lowest with 0 9 The content in adenylic acid deaminase followed to some extent that for adenosine, with many marked differences, the most extreme being voluntary muscle, which contained in the average about 1,000 enzyme units This enzyme also is greatly in excess of the adenosine deaminase in conducting nerve, cerebral cortex and pituitary gland , and in the alimentary distribution we have the proportion reversed No pure adenylic acid deaminase was found in plasma

The above research was supported by a grant from the Irish Medical Research Council

Application of the Feulgen Method to the Study of Viruses

'NUCLEOID' bodies giving a positive Feulgen reaction have been shown to be integral constituents of various kinds of spore bearing bacilli[1] and also of *Bact Coli* and '*Bact paratyphosum*'[2] Photographed in ultra violet light, these bodies proved to possess the specific absorption characteristic of nucleic acid

So far as we are aware, Haagen is the only investigator who has applied this reaction to a virus He has stated[3] that the inclusion bodies of vaccinia give a positive Feulgen reaction, but that the elementary bodies are negative We have been able to confirm Haagen s findings so far as concerns the elementary bodies and the small inclusions which characterize the early stages of infection, but we have invariably obtained a negative result with the large irregular type of inclusion present during the later hours

The Feulgen negative inclusion bodies of vaccinia and the elementary bodies stain red with Giemsa s stain The small Feulgen positive inclusions stain deep reddish purple, while bacteria stain a deep bluish purple Both the elementary bodies and the large forms of psittacosis virus stain a purple rather than a red colour with Giemsa s stain This circumstance induced us to test the various developmental stages of this virus with the Feulgen technique Positive results were obtained both with free elementary bodies in smears made from the spleens of mice which had died of the disease, and with all the various intra cellular stages found in tissue cultures infected with the virus

Through the kindness of Dr G M Findlay, we have also been able to examine smears of lympho granuloma inguinale virus As Findlay, Mackenzie and MacCallum have shown[4] this virus, like psittacosis, produces both large forms and elementary bodies and stains with Castañeda s stain With Giemsa s stain the elementary bodies are stained a colour intermediate between the purple of psittacosis and the red of vaccinia Both elementary bodies and large forms gave a negative result in our hands

Some investigators (for example Herzberg[5]) are doubtful whether psittacosis should be included among the viruses because of the ease with which it stains with dilute Victoria blue and with Castañeda's stain The fact that it is Feulgen positive appears to strengthen this distinction, but on the other hand in lymphogranuloma we have a virus which is at once Castañeda positive and Feulgen negative thus forming an intermediate link between psittacosis on one hand and vaccinia on the other

It will be of interest to apply the Feulgen method to as many viruses as possible and this we propose to do

Points from Foregoing Letters

THE discovery of a large fragment of an additional *Pithecanthropus* skull (consisting of the complete right parietal bone with the adjoining part of the left parietal and a small piece of the occipital bone) is reported from Java by Dr G H R von Koenigswald and Dr Franz Weidenreich This was found in the Trinil formation of Sangiren where an almost complete brain case of *Pithecanthropus* was found last year

A type of sidereal system heretofore unknown is reported by Dr Harlow Shapley, who has based his investigations on long-exposure photographs made with various telescopes at the South African station of the Harvard Observatory The two examples now described resemble globular clusters in uniformity and radial symmetry, numerous faint external gal axies seen through them give them the appearance of supergalaxies, but they are probably members of the local supergalaxy

Dr L Jánossy and Dr A C B Lovell have obtained cloud chamber photographs of cosmic ray showers which extend over several square metres They conclude that the showers consist mainly of electrons, and that in some cases the total energy of the shower may exceed 10^{15} electron volts

The magnetic anisotropy of manganite crystals (monoclinic) is found by Prof K S Krishnan and S Banerjee to be $4 \cdot 0 \times 10^{-6}$ per gm atom of manganese This value, the authors state, shows that the manganese atoms in the crystal cannot be trivalent, but are probably half divalent and half tetravalent

Prof V V Narlikar submits a proof, using the equation of conservation of momentum, that a *radiating* small mass describes a geodesic He also points out that the constancy of the inertial mass is implicit in the equation of momentum itself when the body is not radiating

The infra red absorption and Raman spectra of liquid and gaseous sulphur trioxide have been investigated by Dr H Gerding and Dr J Lecompte who deduce that in the vapour state the molecule of sulphur trioxide has a plane practically symmetrical configuration while in the liquid state the molecule is considerably deformed

A reconsideration of the wave lengths observed in the ultra violet and visible spectra of the night sky by Prof J Cabannes Prof J Dufay and J Gauzit lead the investigators to the conclusion that CH bands probably exist in the spectrum of the night sky at 4300, 3143 and possibly 4050 A

A substance obtained by the steam distillation of yeast extract and apparently containing a mixture of saturated fatty acids is found by Prof E S Cook and C W Kreke to increase by 3½ times the respiration factor (oxygen uptake) of yeast suspensions when added in suitable concentration Capric and undecanoic fatty acids were found to have similar properties In the concentrations thus far investigated the yeast distillate appears to be inhibitory to yeast growth and fermentation, but stimulates the growth of epithelium in tissue cultures

The free ammonia formed in blood after shedding, arises from three sources according to Prof E J Conway and R Cooke These sources are (1) adenosine, (2) adenylpyrophosphate in the red corpuscles and (3) vegetable adenylic acid The authors indicate the probable stages by which the ammonia is formed, and point out that probably the ferment in the red corpuscles and other tissues, except voluntary muscle, is reversibly bound to some inhibiting substance

Research Items

Craniology of African Pygmies

SKELETONS of four African pygmies, acquired for the Musée de Congo of Terveuren by Dr P Schebesta and J Jadin in their expedition to the Ituri Forest in 1934–35, have been examined by Prof J Mateigka and Prof J Maly The first instalment of their report, dealing with the crania, appears in *L Anthropologie* (**48**, 3–4, 1938) Of these skeletons, two are male and two female Of the males, one was of about forty years of age, the female from the same locality was about fifty years of age The skulls were well preserved, and the distinctive sexual characters well marked There was a marked atrophy of the maxillaries, possibly due to the loss of the teeth, which may also have caused a certain facial asymmetry Partial caries and alveolar pyorrhea were present The sutures generally were simple Head length varied from 165 mm to 176 mm, breadth from 128 mm to 136 mm This measurement in the male crania (135 mm and 136 mm) approaches the mean for Spanish skulls and exceeds that recorded for Australian, Vedda and Bushman Head height 122–130 mm is a minimum figure The dimensions of the skull taken together, however, point to the classification of these pygmy skulls with other groups below the mean The cephalic index of 73 56–80 47 ranges from dolichocephalic to brachycephalic They may be classed generally as orthocephalic, with a tendency to metriocephaly The horizontal circumference ranges from 475 mm to 498 mm This indicates that the pygmies do not touch the absolute minimum, as smaller dimensions are found among both primitive and white peoples

Undulant Fever in France

IN a recent *Bulletin of the Health Organization of the League of Nations* (7 Extract No 9) R M Taylor, M Lisbonne L F Vidal and R H Hazemann who made a study of 869 *Brucella* strains isolated from man and animals in France, came to the following conclusions All the classified strains of *Brucella* fall into one of two types, namely, *Br melitensis* and *Br abortus* Of 507 strains isolated from man, 477 (94 per cent) were *Br melitensis* While the *melitensis* type was definitely dangerous to man, *Br abortus* was a relatively unimportant cause of undulant fever, and was essentially an economic and veterinary problem Cases of undulant fever of the *melitensis* type were usually multiple and tended to occur in localized epidemics, while those of the *abortus* variety were almost invariably sporadic The incidence of undulant fever in France reached a peak in the early spring, which is the period of parturition and abortion among domestic animals such as sheep and goats As regards age and sex, clinical undulant fever was found to be rare below the ages of fifteen years and was two or three times more frequent in males than in females Infections in goat and sheep were almost always of the *melitensis* type, whereas cows were the principal hosts of the *abortus* variety The disease was found to occur chiefly among the rural population and in those who were brought in contact with the animals or their carcasses The writers' studies indicated that the risk of infection through contact with animals was decidedly greater than through consumption of raw milk or fresh cheese Sanitary conditions were of little importance in the transmission of the disease

Aerial Vision in Freshwater Grey Mullet

AERIAL vision in fishes, demanding a modification of the under water eye, is a rare development, so that the notes by Dr S L Hora upon the freshwater grey mullet of northern India and Burma (*Mugil corsula*) are welcome, although they do not carry the problem very far (*J Bombay Nat Hist Soc* **40**, 62, 1938) The species habitually moves at the surface of the waters in which it lives with both its eyes well elevated above the surface That it can see in this position is indicated by its active capture of caddis flies, the swarms of which it seems to follow at the surface Yet the stomach contents of some consisted mostly of large numbers of copepods, and others devoured aquatic algæ, so that the fish can apparently see under water as well as in the air Hora also noted that in both media the eye balls showed movements in all directions, as if they were in active use But no experiment has been made to test the efficiency of the organ in either medium, and except that the grey mullet has no structural adaptation like that of the South American 'four eyed fish, *Anableps*, with its bifocal vision, no information is given about the minute structure of the eye itself, to suggest the direction of the aerial modification Information on these points would be of value

Genetics of Millet and *Sorghum*

MILLET (*Panicum miliaceum*) has been grown from the earliest times in India, Africa southern Europe China and Japan Its home may have been in central Asia, where nomad peoples found it useful because of its short period of maturation Mr Rangaswami Ayyangar and his colleagues have studied its genetics (*Madras Agric J*, **26**, 195, 1938) at Coimbatore They find a dominant factor P for purple pigmentation and an intensifier, I, which makes the purple darker The hairiness is governed by at least three factors H_1, H_2, H_3, which are cumulative in effect In grain colours of Madras varieties, a dominant factor O changes buff to olive grey A dominant factor L lightens the glume colour An inhibitor I lightens it further to ivory A third grain colour, reddish orange is recessive to buff, while another dominant factor suppresses the red in reddish orange, making it buff A number of species of *Sorghum* are found (*Current Sci*, **6**, 556) to have varieties with green and others with blue green seedlings, the latter tillering more This colour disappears after forty days and behaves as a dominant to green The African species of *Sorghum* and their hybrids appear to be the origin of the blue green type, which is also found to occur in many other grasses In broom corn, a *Sorghum* with long stalks to the panicle branches, a form occurs with neither auricle nor ligule to the leaves It is a simple recessive to the auriculate ligulate condition (*Proc Indian Acad Sci*, **7**, 286), and also differs in having no basal pulvini and a short spikelet-free area in the panicle branches This makes the earhead very compact with many sterile seeds It presumably represents a mutation from the ordinary broom corn condition

Constitution of the Great Barrier Reef

The Reports of the Great Barrier Reef Committee, 4, Pt 3, Nos 7, 8, 9 (Brisbane Gov Printer, 1938) contain a preliminary account by Prof H C Richards on the boring made in 1937 on Heron Island (lat 23° 26′ S, long 151° 57′ E) at the southern end of the Great Barrier Reef This bore followed on a previous boring made in 1927 on Michaelmas Cay some 700 miles farther north west along the reef The Michaelmas Cay boring failed to reach the underlying old rock platform after a depth of 600 ft It was hoped to bore to 1,200 ft on Heron Island Unfortunately, layers of rock were encountered below 510 ft which necessitated reductions in the size of the casing, and the extreme depth reached was 732 ft Once again the bed rock was not reached Comparison of the two borings shows a remarkable similarity In both it was found that loosely coherent coralline material extends to a depth of approximately 450 ft In both this was succeeded by non coralline material of loosely coherent quartz sand with abundant foraminifera and littoral shell fragments In the Heron Island bore eight siliceous foraminiferal limestone bands were met below the coral of which the thickest was 78 inches, four were of the order of 18 inches to 2 feet and the others quite thin

Oxidation and Reduction

In an article in *Scientia* of September 1938, Prof J R Partington reviews the early history and modern outlook upon the processes of oxidation and reduction, and in particular the application of the oxidation reduction potentials, now generally known as 'redox' potentials, to modern problems Incidentally, he points out the curious resemblance between the electronic theory of oxidation and the ancient theory of phlogiston Metals are now believed to be combinations of positively charged ions and negative electrons, of which the former persist in oxides and cations The process of oxidation involves then the removal of electrons instead of phlogiston It may be noted in this connexion that those metals which are most readily oxidized are those which most readily emit electrons when exposed to light of short wave length In applying the well known thermodynamic equation to the evaluation of the redox potential of an electrode of the quinhydrone type, it was assumed by Ostwald that every reducing or oxidizing agent could be replaced theoretically by hydrogen or oxygen under an appropriate pressure, and Nernst obtained some experimental support for this supposition by pumping hydrogen gas from a thin bulb of palladium immersed in a solution of a reducing agent But since reversible cells giving redox potentials can be set up with solutions of metallic salts in anhydrous solvents like pyridine or acetonitrile, which are unable to furnish hydrogen, some other mechanism must be found, and it is reasonable to postulate the presence of low concentrations of free electrons not only in these but also in all cases, to establish the potential Increasing use of redox indicators is being made with marked success in analytical chemistry, since they undergo reversible changes which are very similar in type to those of the quinhydrone electrode and are accompanied by colour changes at definite potentials, corresponding with definite electron concentrations in the redox system Even more interesting is the field opening up in the study of biological processes, which involve oxidation and reduction and are catalysed by specific enzymes It is hoped that it may be possible to extend the use of 'potential mediators' in order to overcome the difficulty presented by the thermodynamic irreversibility of many of these important reactions Much remains to be done in developing the study of one of the oldest known types of chemical reaction

Search for Super-Novæ

F Zwicky (*Phys Rev*, 53, 1019) has published a preliminary account of a systematic study of super novæ The basis of the work was a photographic survey with an 18 in telescope of aperture *f*/2 Three super novæ were discovered, corresponding to a frequency of occurrence of one nova per galaxy per six hundred years It was shown that the spectra are distinct from those of all other stellar objects and that the absolute brightness may often be far higher than that of any other star It is concluded that the existence of two classes of temporary stars, the ordinary and super novæ, is established beyond doubt

Draining the Cambridge Fens

The greater part of the fenlands of northern Cambridgeshire were drained during the first half of the seventeenth century The enterprise was very successful at first, but difficulties soon began to become evident, some of which have continued to be prominent right up to the present day, as was shown in a paper read at Cambridge before Section E (Geography) of the British Association by Dr H C Darby These permanent difficulties are associated with the lowering of the peat level and with the outfalls of the fen rivers As the peat was drained, it rapidly sank in level partly owing to shrinkage and partly to the wasting away of its surface by bacterial action, so that in time its level became lower than that of the drainage channels This difference of level may be seen to day along many of the fen rivers, which are now higher than the land through which they flow In the eighteenth century, wind mills were introduced, but as the surface level continued to subside, their limitations made them inadequate to the requirements In 1800 steam pumping was discussed, but it was not until 1820 that a steam engine by Watt was set up to work a scoop wheel at Bottisham Thirty years later it is estimated that sixty four steam plants were in operation Difficulties have also arisen at the estuaries of the fenland rivers, which have not a sufficient current to carry their silt out to sea The most recent effort to deal with this problem is the large scale working model of the Wash and its estuaries constructed by the Great Ouse Catchment Board Another type of problem is presented by the sluices which are necessary to prevent the tidal waters from passing up the rivers A case in point is Denver Sluice immediately below which the Hundred Foot River drains directly into the tidal Ouse When there is much upland water passing down this river, the level in the Ouse does not fall sufficiently to admit of the sluice gates being opened, with consequent risk of flooding

Function of Education

THE discussion on Education for a Changing Society' arranged by Section L (Educational Science) of the British Association on August 19 and 22 was maintained at a high level well worthy of the crowded audiences which it attracted

In opening the discussion, Mr W H Robinson dealt with the senior school, which he described as pre eminently the school of the people, the vast majority of the electorate Most of the pupils of the senior school would receive no further organized education but would be educated by their environment, both physical and mental He suggested that the essential function of school in a changing society is to teach pupils the art of self education to be continued through life, and to give them a conviction that education is not a thing of school alone The school should provide a connecting thread running through the educative influence of the cinema, radio, picture paper and environment generally Accordingly, the school must be related at all points to the community and as the Hadow Committee insisted, the curriculum must be thought of in terms of experience and activity rather than of knowledge to be acquired and facts to be stored

The years from eleven to fifteen Mr Robinson urged, should be used to consolidate the training already given by taking into full account the psychology of the adolescent of this age By becoming leaders of the school community by experience of the organization of school activities by discussion and attempts at agreement, they would learn by experience the basic facts on which our democracy is based and the lines along which it must develop In this way they would learn the necessity for patience persuasion and compromise, respect for the opinions and form of action of others, and that toleration is better than coercion This learning through experience, Mr Robinson considers is more important than lessons, and the great need appears to be for the development of a technique for developing the active co operation of the pupil in the work of self education for life

The second paper by Miss Ruth Dawson, also dealt with the senior school and emphasized the importance in view of the background and environment of the modern child, of giving an education designed not to accumulate facts but to train the mind to make right judgments Once again reference was made to the aims set forth in the Hadow Report and the importance of all subjects in the curriculum contributing to the formation and strengthening of character, the training of tastes which would fill and dignify leisure, and to the awakening and guiding of intelligence Miss Dawson referred in illustration to the use and opportunities of physical training, domestic science, arts and crafts, drama, etc

The part of the secondary school was discussed in papers by Dr P T Freeman and Miss Muriel Davies which presented two opposite, but not necessarily opposed, points of view and were afterwards rather severely criticized by Mr H G Wells Dr Freeman stressed the importance of discipline and urged that it is necessary not only to arouse interest but also to demand effort He deplored the recent agitation against homework and said that, in spite of the independence of the modern child, there is a lack of vitality and willingness to tackle difficulties Dr Freeman urged the value of Latin and Euclid in training particularly as teaching children not to accept statements without adequate evidence He advocated a three year course in biology as a means of conveying information about sex and, while supporting an extension of the teaching of civics and economics, considers that over-emphasis on apparatus in physical training is dangerous Although he was severely taken to task by Mr Wells for his advocacy of Officers Training Corps, his opinion of the value of such training in developing not only discipline but also self reliance will certainly find strong support

Miss Muriel Davies, on the other hand, devoted much of her time to an analysis of social conditions and of the way in which inequalities are perpetuated in our present educational system She pleaded eloquently for a unification of our educational system particularly in the ranks of the teacher, the abolition of distinctions in salary scales between elementary and secondary school teachers and the evolution of a system of education for social progress rather than for individual advancement Miss Davies s address contained many almost startling suggestions, designed to promote co operation rather than competition and to break down class distinctions such as the abolition of formal hours and holidays the education of rich and poor together, the requiring of all teachers to spend some time in elementary schools, but the vision and idealism of the address warmly commended it to the large audience, not the less because it was constructive and forward looking She deprecated the use of prizes and marks for stimulating effort, but although she advocated more freedom of choice for children in their actual work both in and out of the school, her insistence on the encouragement of the community spirit and suggestion for a group system in place of the house or house prefect system should have safeguarded her from Mr Wells s stricture

Continuing the discussion on August 22 Mr J Paley Yorke dealt with the functions and work of the junior technical school, the importance of which is enhanced by the decay of the apprenticeship system He laid particular stress upon the importance of the staff possessing adequate industrial experience in view of its bearing on the content and presentation of the training Dr W A Richardson discussed the place of the technical college Pointing out the disparity between our knowledge of the material world and our knowledge of mind and social relations, he stressed the need for research in the latter field Social conditions profoundly affect the work of technical colleges, as of all education and educational ideals, and Dr Richardson instanced the danger that the rearmament programme will have untoward effects in the educational field There are wide differences between technical colleges, and the voluntary system has a serious defect in the leakage of students, many of whom do not stay the course Moreover, difficulties also arise because often the students attend primarily for training in occupations other than that which they are following at the moment There is less leakage of students entering technical colleges from the junior technical schools than of students of any other type

Dr Richardson considers that the raising of the school age would assist the work of the technical colleges, but if education is to be effective, it must be compulsory until the age of mental maturity—at least until eighteen The idea of the local college, which is a community of students whose main purpose in attending is educational, and not social, but for whom the authorities must provide facilities for social and physical development in the fullest sense is gaining ground Such colleges would necessarily continue to have a vocational and industrial bias endeavouring to develop skill as well as to impart technical knowledge and training in administration both in the industrial and the civic sphere

Mr F Pick whose paper drew the warm approval of Mr H G Wells, criticized education for failing to give to the new subjects of an industrial civilization the breadth and quality which is given to the older subjects bred in the classic ages He argued for a new type of university of the eye and hand as distinct from that of the voice and the pen It should be possible to illuminate the accumulated knowledge of trade and industry with a wisdom and understanding which would make it a suitable medium for a liberal education The trained and broadened mind should be applied to the building up out of the mass of knowledge which they embody, human sciences to rank with ethics, politics, economics and sociology

Prof Winifred Cullis followed with a final paper in which she dealt with some questions confronting the universities in the changing world With regard to the aims of university education there is a great consensus of opinion as expressed both by staff and by students, and the stress is laid on training for living rather than for a livelihood She referred to a number of particular problems raised in recent reports such as the question whether a specialist training for particular careers is the best for developing leaders of informed public opinion, for men and women who are to be politicians, administrators, journalists or teachers Again there is the question whether post graduate teaching should be concentrated in particular universities, in which connexion Prof Cullis referred to the backward position of post graduate education in medicine in Great Britain compared with that in other countries The extension of the system of individual tutorship to all universities, and increased facilities for short term exchanges of staff between different universities both in Great Britain and abroad, and the provision of increasing numbers of residential halls are all matters requiring consideration

Prof Cullis laid particular stress on the importance of greater attention to the question of the health of students and strongly supported the demand for physical education and health services at the universities She is in favour of compulsory medical examinations at regular intervals pointing out that it is often the students who can least afford medical advice who most need it and that such examination could often prevent serious illness developing later She outlined a number of health insurance schemes both optional and compulsory, which have been developed for students in Great Britain or abroad, and finally stressed the importance of including training for the responsibilities of citizenship

Lord Stamp, who opened the discussion was decidedly more critical than Mr H G Wells of Mr Pick's paper He pointed out that we cannot say what changes in education are desirable until we have decided what is the right direction for such changes to take what is the optimum speed at which they should be made, how they can be made with the least waste and what should be the correct agencies for bringing them about Some account must now be taken of the changes in the rate of growth of the population and of its possible physical obsolescence, and Lord Stamp referred particularly to the importance of considering training which would give the right outlook and background to those occupying the intermediate executive positions since they have so much influence on the selection from the younger men and women of those who in later life will occupy the positions of highest responsibility He strongly supported the idea of refresher classes and post graduate courses for those already occupying business or professional posts Sir Richard Livingstone criticized the teaching of history and philosophy at an age too early for adequate appreciation, and expressed his regret that adult education had not been included in the discussion

New Science Buildings at Shrewsbury School

ON September 24, Sir William Bragg president of the Royal Society, opened the new science building at Shrewsbury School Charles Darwin was at the School from 1818 until 1825, and the building, hitherto used for science teaching, erected in 1903, was named after him It has been considerably re modelled and improved for chemistry teaching under the present building programme The new building was dedicated "in thankful commemoration of the life and work of Charles Darwin"

The new science building comprises two floors, the ground floor being devoted to physics, and the first floor to biology The latter floor is some two thirds the area of the ground floor and is masked on three faces by roof slopes, it being the desire that this new building should conform to the general style of adjacent buildings which are mostly of one story The construction is of brick with hollow tile fire resisting floors, and tiled roofs with asphalt flats between All rooms are fully plastered and floors generally are of teak blocks Heating is by low pressure hot water radiators

The ground floor (physics) has two large elementary laboratories, each for 26 students, with a common preparation – store room, an advanced laboratory for 16 students, two lecture rooms to seat 26 each, a large store room and a photographic dark room Both elementary laboratories are alike in fitments, long fixed double sided table type benches, having gas and electric services, occupy the middle of the room Enclosed balance cases in groups are disposed around the walls, and two large sinks are conveniently situated in each room The advanced laboratory is fitted with a service shelf 15 in wide around three sides of the room (having gas water and electric services thereon) which when used in conjunction with the four strong loose tables gives considerable flexibility

The elementary laboratories and lecture rooms contain fully equipped demonstration benches and a certain amount of local storage is provided in all rooms All rooms have dark blinds Free wall space is fitted with battens for fixing and hanging apparatus and the laboratories have beams suspended from the ceiling for the usual physical experiments Built in slate galvanometer shelves are provided in convenient positions those in the lecture rooms having measuring leads and 12 volt light leads connected to the demonstration benches for demonstration work with mirror galvanometer and ground glass scale

Large yellow glass boards (in place of the more usual blackboards) have been used throughout Experimental electrical services consist of switch plugs to all working spaces which in the elementary laboratories can be used on the 230 volts A C supply or alternatively on 12 volts A C one pair of leads only being used (designed to avoid varying voltage drops) Voltage reduction is by step down transformer and change over switch under the supervision of the master Direct current supplies for the advanced laboratory and all demonstration benches at 24 volts is provided from a battery of cells and an oxide cathode rectifier interchange of voltage being carried out by plug and socket distribution board arrangement All the D C equipment is located on one wall of the advanced laboratory and is available for instructional purposes

The first floor (biology) consists of two very large well lighted laboratories a common preparation room store room greenhouse and a small private research room for the masters use Except for incubator accommodation in one room and aquaria in the other both large laboratories are identical in fitments one portion of each room being laid out with flat topped tables and seats for 24 students (for theoretical work) with fully equipped demonstration bench projection screen and yellow board the other portion fitted with low benches (for 26 students) for microscope and dissecting work These latter benches have gas points and microscope light points fitted and are designed to accommodate microscopes and their lamps when not in use There are two large wash up sinks and drainers in each laboratory with provision for draining and storing dissecting boards and around all walls one continuous shelf allows of the display of natural history specimens and specimens in embryo North east top lights are provided over that part of each laboratory devoted to practical work and dark blinds are provided throughout Storage and preparation rooms provide accommodation graded to suit all sizes from small stain bottle racks to large diagram charts

The old building has been considerably re modelled internally to provide the necessary accommodation exclusively for chemistry comprising two, large elementary laboratories (one for fifth form work) two large lecture rooms an advanced (specialist) laboratory for 14 two balance rooms the usual store and preparation rooms and a small science library Existing fittings have been modernized new chemistry working benches provided where necessary and new ranges of fume cupboards in the fifth form laboratory and advanced laboratory have been installed ventilated by a centrifugal fan and acid resisting ducting New roof lights have been added to improve the natural lighting of the rooms

The architects for the work were Messrs Munby and Smith of 9 Old Square Lincoln s Inn London

---

Effect of Inbreeding of Physiologic Races of Rust

THE recognition of the + and − strains in rust fungi and the way in which the bi nucleate aecial condition must be preceded by mycelial fusion of + and − strains or the introduction of pycniospore containing nectar of the opposite strain has led to the possibility of the study of inbred physiologic races Johnson and Newton (*Can J Res* 16 1938) have made a study of the effects produced in *Puccinia graminis Tritici* Erikss and Henn Cultures have been started from a single urediospore and these have been followed through their cycle selfing being brought about by mixing pycniospore containing nectar of pustules of the isolated race

It is found in several of the isolated races when selfing has been repeated for several generations that new features are liable to appear Thus races which originally had the normal red uredial colour have produced types with greyish brown orange or white uredia—features which are of extremely rare occurrence in Nature The proportions in which these abnormalities of uredial colour appear suggest a genetic relation in which greyish brown and orange are dominant to white and the normal red to the other three

Also in such inbred races types have appeared with decreased vigour of uredia as evidenced by a tendency towards or failure of the uredial pustules to break through the host epidermis other types have shown a weakening of pathogenicity as compared by inoculation of named varieties of wheat and still others have failed to produce aecia and instead formed urediospores or teliospores on the barberry

The authors point out that mutations have been reported several times for the rusts and the evidence from the present work suggests that certain physiologic races are in a mutable condition Owing to the multiplicity of physiologic races and the heterothallic nature of the rusts in Nature the mutants will *seldom occur in the homozygous condition* When inbreeding is maintained for several generations it is probable that homozygous recessive types are segregated (or possibly additional mutations occur during the selfing stages on barberry)

In the group of the rusts short cycle forms are of relatively common occurrence and may tend towards the production of autoecious species In this connexion it is of interest to find in *Puccinia graminis* a mutant in which the aecial stage is eliminated though the urediospores produced on the barberry are only capable of infecting wheat seedlings so that the physiologic race is still heteroecious

Science News a Century Ago

Fermentation an Act of Vegetation

'M Turpin has lately published his observations upon certain phenomena, which he considers sufficient to show, that the act of fermentation, concerning which chemists have been so much embarrassed, is owing to the rapid development of infusorial plants He states, that all yeast, of whatever description, derives its origin from the separation from organic tissues, whether animal or vegetable, of spherical particles of extreme minuteness, which particles, after a certain time, rise to the surface of the fluids in which they are immersed, and there germinate No doubt the yeast of beer consists of minute molecular matter, the particles of which are globular, and that these particles produce, from their sides, other particles like themselves, which eventually separate from the parent, but we do not know that they are *therefore* plants (*Athenæum*, October 20, 1838)

Smoke Abatement

The *Mechanics' Magazine* of October 20, 1838, when describing a plan by Iveson for effecting the combustion of smoke, which had been tried in the steamer *Royal Adelaide*, remarked Smoke has always been regarded as a nuisance As the age of steam advanced, and as its benefits were extended over, and enriched the face of the earth, so did the concomitant evil, smoke, throw a cloud abroad which bade fair to obscure the face of the sky So great became the evil, that in process of time every one not directly interested in its cause complained aloud, and seemed willing to forego the grand effects of the steam engine rather than put up with its smoke Petition after petition poured into the Houses of Parliament praying the legislature to compel the manufactories to put out their fires or swallow their smoke Learned societies offered premiums to incite their members to search for an antidote A parliamentary committee was appointed to examine into the subject An Act was the result of this inquiry rendering manufacturers indictable for a nuisance if the smoke of their chimneys annoyed their neighbours "

The Transatlantic Steamship *Liverpool*

On October 20, 1838, the S S *Liverpool*, the largest vessel built on the banks of the Mersey up to that time, sailed from Liverpool on her maiden voyage to New York Her length was given by the Surveyor of Lloyd's Register of Shipping as 218 ft 4 in , her breadth 31 ft 4 in , her tonnage by builders' measurement $1{,}042\frac{3}{94}$ tons, and her steam boat tonnage $559\frac{1}{4}$ tons She was not originally intended for work on the Atlantic, and to strengthen her for the passage she was fitted with iron beams over the engine and boiler rooms, and these beams were braced together with fore and aft iron rods Other iron rods were used to strengthen the paddle boxes She had a two cylinder side lever engine of 468 horse power, the steam pressure being about 5 lb. per sq in Leaving Liverpool on October 20, when six days out it was realized that her coal would not last the voyage, so she returned to Cork to refill her bunkers Sailing again from Cork on November 6, she reached New York in 16 days 17 hours, her best day's run being 242 miles. Between October 1838 and the end of 1840, she crossed and recrossed seven times

Concepts of Human Progress

A FORTNIGHT ago, in an article entitled The Promotion of Peace", we referred to events which claimed the interest of the whole civilized world and upon the settlement of which depended the lives of millions of people We were able to record that as the result of consultations between statesmen an agreement was reached which though its justice may be disputed prevented nations from being thrust wantonly over the precipice into a world war Thanks to the facilities of rapid transit and world wide direct communication which science has placed at the service of statesman and press, the full weight of the world's judgment was brought to bear as the hour of crisis drew near until perhaps—who can say?—it turned the scale Had such rapid and extensive means of making plain the judgment and trend of opinion among peoples been available in 1914, actions which resulted in the Great War might have been averted

In the first flush of enthusiasm at the recent preservation of peace, it seemed that the crisis through which we had passed had quickened perception of values in the essentials of life, to most of which we had been prepared to bid a long and perhaps an eternal, farewell Hope, founded on the promise of the Anglo German pact, looked forward to the removal of the menace of war to set mankind free for the pursuit without distraction not merely of enjoyment of the advantages which the advancement of scientific knowledge holds out for the future, greater even than the wonders with which it has endowed mankind in the past generation, but also of real and substantial progress, in a healthier atmosphere, in the scientific study and resolution of the problems which lie at the root of world economic and social unrest

Disillusion has been rapid complete and painful The first task to which we are now bidden to turn of necessity and at redoubled speed is armament and provision for defence So much the more then are energies and resources withdrawn from the advancement of what we had come to realize were the essential needs of future development in human life The sole palliation is that our aim is the preservation of the freedom of the spirit which alone consorts with the dignity of man

Let there be no illusions as to the character of the struggle which will be involved in modern warfare It is a reversion to the methods of savagery In the scale of development of human society war has played a useful and, biologically speaking, a necessary part The society which at a certain stage of development depends upon the prowess of heroes pitted against their like breeds heroes to ensure qualities essential to its survival in the struggle for existence But the day of heroes in war is past Modern war, which will be waged from the air, is the warfare of the primitive head hunter, in which the raider returns triumphant from his raid after the slaughter indiscriminately of man, woman or child The principles of warfare are unchanged— 'Find the forces of the enemy and destroy them" , but those forces are no longer armed forces , they are the whole people, whose morale must be destroyed Could any parallel be closer to the head hunter, who brings back with each head something of the spiritual force of the enemy he has slain ?

In the development—evolution in the popular sense—of progressive human societies, the line of advance has been towards ever increasing aggregations of individuals—from family to tribe and from tribe, through a regular gradation of political units to empire If the warlike qualities have played their part in each of these forms of human association in securing that independence of existence which is essential for internal development there has been an equal and parallel development of those qualities in the individual which make for just and harmonious association between the members of a social group—the qualities of justice of capacity for co operation of consideration for others and care for the weak It is these qualities which give solidarity to the group and are no less conducive to its survival than the warlike qualities which preserve it from aggression from outside

Such social characters are however not only the essentials of internal peace and advancement but also they react on those higher qualities of the human mind in the exercise of which man approaches most nearly to exhibition of his specifically human characters unaffected by cultural divergence These higher manifestations of his spirit if in origin based upon a tradition peculiar to his group nevertheless in their highest development transcend such limitations Of such are literature art and scientific knowledge which when they attain their highest powers speak a universal language

At the same time with each advance in social gradation the system of social and religious ethics is extended to embrace a wider circle until in certain of their concepts they too approach a universal appeal to mankind at large rather than a restricted cultural group No one has ever questioned that in these higher manifestations of the spirit man attains and will attain his highest development whatever may be his advancement in the field of the material Further it is a matter of experience no less than a postulate of reason that for their full and complete expansion and growth free intercourse and exchange of experience and thought are essential without barriers of race or political frontier to exclude any form of intellectual development as alien While similarly the ethical system in the long run whether it be bound to a specific form of religious belief or not will come to recognize the claims of ethical concepts common to humanity at large irrespective of creed

In the intercourse between national groups which is become an essential condition of the development of the activities of the higher faculties civilized man has transcended the group to embrace humanity as a whole As men bend their minds to the problems which arise in this extended outlook if advancement is to continue it will demand more and more a scientific approach to these problems which however much they may depend upon conditions within the group are world wide in application or in effect

In an increasing degree these problems will arise in connexion with the backward no less than with advanced peoples An ever growing sense of the responsibility of Western civilization to protect primitive races from the more harmful and disintegrating effects of its own impact on their culture and institutions will by the logic of circumstances carry conviction that both wisdom and justice demand that this state of tutelage no longer susceptible of exploitation for national advantage or prestige should carry with it an obligation to develop in these peoples not only the capacity to deal with the special problems of their own government but also to co operate with the white man in the solution of questions of wider import Events of the last decade more especially in the economic field have driven home forcibly the lesson that there are few peoples so remote so self sufficient—in short so primitive—as to escape the repercussions of the major crises at the heart of civilization Pursuit of the material benefits conferred in the spread of Western civilization has led to the assumption all too readily that ultimately Western ways of thought Western beliefs will set the world standard In the reaction which is at hand—nay which has already begun in Africa and in the East—understanding tolerance and breadth of view can alone bring about the adjustment which will avert conflict

Unfortunately man s political and economic advancement has lagged behind his intellectual and material progress The League of Nations which represented an attempt to attain an aggregation transcending the national group has accomplished much valuable work in the study of problems in which scientific and intellectual co operation was possible without regard to national grouping Nevertheless it has failed in its main object because in the international sphere its approach to political problems has been upon a national rather than an international basis If the Anglo German pact were in fact the first step towards a policy of discussion and conciliation in which discussion proceeded to each specific problem with a scientific outlook and the aim of human and not national advancement and be it added without the accompaniment of the rattle of arms we might indeed look for the approach of an era of which the League of Nations was but the false dawn

The Critic Triumphant

Retrospect
an Autobiography By T A Rickard Pp xi+402+5 plates (New York and London McGraw Hill Book Co Inc 1937) 12s 6d

MAINLY this retrospect is the story of the author s life the life of a man who successively was mining engineer and editor retiring then to enter with no less success upon a wider scholarship Of less sustained interest it includes stories of travel of contact with American presidents and of selections from speeches made and addresses given

Born in the mining tradition and trained in an *alma mater* the Royal School of Mines London of which he remains throughout a loyal son this life story is of a man high principled and sensitive who became eminent in the profession and practised world widely but principally in the United States of America until his particular contact with financial methods provoked such distaste that the opportunity offering he turned aside to concentrate upon technical literature for which he had a liking and an already widely exercised gift

Becoming then successfully editor of the two principal mining periodicals in the United States and one leading periodical in London Rickard served the profession greatly by frank criticism of current events and tendencies never one who trembled to think he courageously ventured to speak sometimes in mordant manner of mock humility His editorials were instinct with his individual and challenging personality If nothing he ever wrote was uninteresting nothing uninformative these editorials were nevertheless his excellencies To them his readers on both sides of the Atlantic looked forward and remembering now look back The driving force behind his fluent pen was a burning almost an explosive exasperation with sloppy thought loose expression and dubious ethics To him careful writing shaped the mind as the tool shapes the hand He encouraged mining engineers to be frank and honest with themselves for

> This above all to thine own self be true
> And it must follow as the night the day
> Thou canst not then be false to any man

The flag of frank and noble criticism Rickard flew gaily Independent and subservient to none criticizing the thing and not the person he was happy in the work of creating a sound public opinion in the mining world Approval was not often expressed it was not his line if doings were left alone it might be taken that they had a measure of his approval or were not worthy of his pen Nevertheless Rickard in addition to admirers had a host of personal friends his sparkle and radiant alertness making him an enjoyable companion in spite of a pardonable egotism With this happiness there came however a growing lament that personal hurt was occasionally felt though not intentionally given But his criticism being impersonal there was no bitterness and being effective his work became complete So again he opportunely turned aside now to enter the paths of the wider scholarship

Carrying his critical faculty and his knowledge of metals into archæological and anthropological research and offering them in that field with real humility Rickard has been of signal service in correcting some assumptions made on incomplete metallurgical knowledge and in making a scholarly contribution in his Man and Metals the impulse to writing which lay in the provoking lack of appreciation by Wells in his Outline of History of the important part played by metals in man s development and history

All these services the profession on both sides of the Atlantic has recognized by its highest awards and appreciative citations the occasions receiving some description in this retrospect An editor lives in his editorials an author in his books and Rickard having been both there might remain little beyond episodes and names for an autobiography to disclose But into this retrospect a new interweaving of personal emotion with a universal theme is brought the love of a man for his country Gradually the story is unfolded of a cultured Englishman living long in the United States and becoming there almost a public character finding himself with the entry of America into the Great War at last in such completeness of sympathy with the country and the people as to feel that in all spiritual essentials that country and his England were as one with the natural consequence that to remove the last barrier to those around him he became an American citizen only then in deep disappointment and dismay to find himself, or so he thought, not accepted as a 100 per cent American not to be until he shed his English culture That being impossible he crossed into British Columbia, where with great contentment he became British again

Dominant personalities have their foibles it is as though the finite were necessary to preserve infinity from nothingness and it is all in keeping that in this retrospect occasional trivialities appear and that in places the straining for impressiveness is too evident But such foibles are part and parcel of a man the profession holds in honour and friends hold in esteem and affection Englishmen too will be proud of this stalwart countryman of theirs Accordingly this lively and most interesting story of the critic in action and of the man in intimacy makes a wide and informative human appeal

S J TRUSCOTT

Elementary Work in Zoology

Laboratory Studies in Comparative Anatomy By Dr W C Senning (McGraw Hill Publications in the Zoological Sciences) Pp ix+188 (New York and London McGraw Hill Book Co Inc 1937) 10*s* 6*d*

HERE is the method of conducting the first year course in comparative anatomy at Cornell The student is to provide himself with a text book drawing materials and specified dissecting instruments Then he is to have a set of outline plates some filled in for use with this manual—and he is told precisely how to fill up the outlines These are to present to the student readily available summarised information Three animals namely the shark a newt (*Necturus*) and the cat are chosen to supply a structural framework for subsequently acquired knowledge the student by his careful studies to absorb as much information as can be grasped The student is also indulged in oral discussions by the laboratory instructor and oral and written quizzes and dissection checks Let us say at once that the author has carried out his ideas admirably and the student is to draw figures of what he has learnt from his dissections on fifty four plates He will be an encyclopædia of facts about his three animals and presumably he will have learnt a little dissection and some elements of drawing his chief asset will be that he has learnt to observe and record topography with accuracy his memory is improved and he has acquired much information

But we deduce from the preface that the author aims to prepare his students to do independent work The reviewer has prepared or edited more than a dozen such laboratory manuals for laboratory notebooks are the same thing spaced to leave sheets for drawings He had produced some with as detailed instructions as here—and he found them very useful for instructing large classes especially useful for students who happened to be supplied with indifferent demonstrators such produced the note books in an almost verbally perfect manner for examiners who wanted facts alone Many of his most elementary students were medicals and they desirous of putting behind them a disagreeable first M B were happy Their joyous life continued for they kept the same compartment of mind for anatomy and only had to develop a second chamber for physiology the two not provided with communicating doors until much later when the students learnt that their business was with a living animal

To the real student of science such manuals were fatal and from the commencement the reviewer began to whittle them down To be of any subsequent use or to employ his knowledge for his own pleasure a student must acquire independence and be allowed considerable latitude in choice of interests and methods The anatomy of this manual is not science—this remark applies also to most text books—and indeed is boring to the young The latter centres his interest on the living animal how it lives moves and reproduces in other words is adapted to its place in the world He then demands how the functions consequent on this life are performed and what sort of organs produce them The interest of comparative anatomy is not closed but the approach is from the living to the dead for the latter can only be understood in the life of the former

The laboratory instructor has not the function of driving facts into dull minds but to encourage his pupils to inquire for themselves and to help them to do so Zoology will be killed by the use of such methods as suggested in this manual methods in vogue when the idea of evolution was very young but completely past to day Huxley was a great teacher of comparative anatomy but his most used book was his Comparative Physiology which can profitably be read as an introduction to anatomy even to day

Are the methods of this manual those which are commonly adopted in American universities ? If so the reviewer understands why he has repeatedly had to place trained American students in his most elementary classes

The Teaching of Chemistry

(1) A Higher School Certificate Inorganic Chemistry

By G. H. J. Adlam and Leslie Slater Price. Pp. viii+624. (London: John Murray, 1938.) 8s. *6d.*

(2) Inorganic Chemistry for Schools and Colleges

By Leonard A. Coles. Pp. 384. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1938.) 6s.

(3) A Modern School Chemistry

By A. J. Mee. (Dent's Modern Science Series.) Pp. ix+500+9 plates. (London: J. M. Dent and Sons, Ltd., 1938.) 4s. *6d.*

(4) Elementary Inorganic Chemistry

By Sylvanus J. Smith. Pp. viii+400. (London: Macmillan and Co., Ltd., 1938.) 4s. *6d.*

THE teaching of science to-day forms an important part of the curriculum of our public and secondary schools. The standard of teaching in chemistry was probably never higher than it is now and the number of pupils passing through the advanced courses in science is greater than ever. There is, therefore, a need for really sound elementary and intermediate text-books of chemistry like the four now under review.

All are intended for use in schools with pupils taking the matriculation and higher school certificate examinations. Each possesses qualities that will commend it to the discerning science master. They all appear to cover the subject fully, they are well illustrated and contain plenty of questions. Indeed, there are no fewer than 800 in Mr. Mee's book, whilst Mr. Smith not only includes a selection after each chapter but also gives a series of complete test papers at the end of the text. The fact that all these authors have included carefully graded exercises for the pupil to work through is an indication of the importance they attach to this essential part of schoolwork in chemistry. Suggestions are also made for further reading and these will doubtless attract the keener pupils, but it should not be overlooked that the study of chemistry in schools is a comparative one, and even the best pupils will find their memories taxed unduly if they are not guided in their reading.

The universities obtain their science students from the pupils who have passed through the courses for which these books have been written. Students who have used such books with care and understanding should enter the university with a sound foundation of knowledge in chemistry.

(1) The high standard now attained in chemistry as taught in secondary schools is demonstrated in the first of the books under notice. This might well be expected since one of the authors is the experienced editor of the *School Science Review*. It is arranged in three parts and altogether extends to fifty-nine chapters. The two major parts deal respectively with general and theoretical principles, and a detailed description of the elements and their commoner compounds. The third part gives a short account of the chemistry and physics of the atom, radioactivity and related phenomena.

Among the more noteworthy features of this work are the lucid accounts of recent developments, such as the preparation and study of heavy water and the modern views on valency and atomic structure. The references to physical chemistry are adequate, whilst those organic compounds of which a knowledge is essential for an understanding of the general properties of carbon are also described.

(2) Mr. Coles's "Inorganic Chemistry," he says, 'deals only with the material side of chemistry' and leaves physical chemistry to be studied elsewhere. It does, however, cover the subject concisely and fully, giving a comprehensive account of the metals, following a scheme based upon the periodic classification of the elements and describing the latest industrial and laboratory practice. The order of treatment is unusual. Chapters on hydrogen and water precede those on the inert gases, the alkali metals, the coinage metals, etc., as the author proceeds through the groups of the periodic table. In his hands the result is very successful.

(3) Mr. Mee has aimed at providing a complete text-book of chemistry for schools as far as the standard required for the school certificate examination. Actually he has gone rather beyond his original intention, for he includes a good deal of higher work (for example, the chapters on the hydrocarbons and "Some Important Carbon Compounds") as well as sections dealing with simple qualitative and volumetric analysis. The practical experiments selected for classwork are designed for completion within a working period of forty-five minutes.

(4) Conciseness and completeness characterize Mr. Smith's "Elementary Inorganic Chemistry",

which follows well tried lines in its manner of treatment, upon which much thought has evidently been spent in order to produce an up to date and accurate text book The early chapters give the methods and principles of chemistry and are followed by others dealing in detail with the non-metallic elements and their compounds The metals, about a dozen of which are described are dismissed in sixty pages Thus the book meets the requirements of those who wish to proceed further with chemistry and also of those who will discontinue the subject after leaving school These latter should however be able to take away an impression of chemistry that will be of use in after life For the teacher, this book has a convenient three page index to experimental work in addition to a full general index

The Ways of the Weather

Weather Science for Everybody
By Prof David Brunt (Changing World Library) Pp xii+170 + 6 plates (London Watts and Co 1936) 2*s* 6*d* net

APTLY was meteorology described half a century ago as the Cinderella of the Sciences" in those days it was a humble study indeed, attractive in the main only to amateurs and scorned by the majority of physicists But Cinderella, as we know, could not be kept in the background , eventually she triumphed over her elder and more ambitious sisters Is it to be the same with meteorology ? From the utilitarian point of view the answer must surely be Yes Having regard, in particular, to the future development of weather forecasting and to the potentialities of stratospheric flight it is indisputable that meteorology has the major part of a very important career still ahead

Realization of this rather obvious fact seems to have come earlier to Germany, the United States and several other nations than to Great Britain For here and, indeed, throughout the entire Empire, there is still but one professorship of meteorology—at the Imperial College of Science and Technology, London Prof D Brunt, who now holds that solitary post, is known to meteorologists all over the world for his valuable treatise Physical and Dynamical Meteorology", first published in 1934 Having thus catered for the more learned brethren—those mathematical physicists who seek to solve the many obscure problems of the atmosphere—Prof Brunt has wisely turned his energies to instructing the laity Wisely, we say, because educational authorities, like business chiefs, are necessarily guided in the provision of their supply by consideration of the demand If meteorology is to take its proper place among the sciences taught in our universities, there must be the requisite plea from the younger generation for facilities for tuition This plea is most likely to be incited by popular books of the kind that Prof Brunt has written

The little work before us is one of the best of its type in the English language Tersely, simply and unpretentiously it sets forth as much of its subject as can be understood by the ordinary reader not at all heavily equipped with mathematical and physical training Doubtless in the knowledge that many people have the habit of glancing at the beginning and end of a book before deciding to read it through the author starts and finishes with chapters certain to have a wide appeal— Weather and Human Affairs in Peace and War and How Climate and Weather Affect Health and Comfort It is safe to say that few potential readers thus caught by Prof Brunt's wiles will fail to follow him through the remaining twelve chapters While all fourteen are meritorious those on radiation and the world's climates may be singled out for special mention

Among the occasional slips noted are a misleading account of the methods of infra red photography on p 40, an erroneous specification (temperature for pressure) of the ordinates in the diagram on p 98, and the assertion on pp 142 143 that the winters from 1930-31 to 1935 36 were all fairly mild in London Actually, the winter of 1933-34 was the third coldest of the present century at Greenwich Observatory, with a mean temperature about 2° F below the average Surely too, the English spring repeatedly refutes Prof Brunt's statement on p 65 that snow can reach the ground only when the temperature even at the ground is down to freezing point, or at most a degree or two above it ' There are numerous records of true snow flakes (as distinct from soft hail) having been observed during March and April on occasions when the surface air temperature exceeded 40° F

In view of its modest price, Prof Brunt's book is very well produced and most generously illustrated, not only with line-diagrams but also with several excellent photographs **E L HAWKE**

Annals of the Solar Physics Observatory, Cambridge Vol 5, Part 1 The Spectrum of Fe II By Dr J C Dobbie Pp v+59+4 plates (Cambridge At the University Press, 1938) 7s 6d net

PART I of vol 5 of the 'Annals of the Solar Physics Observatory Cambridge (by Dr J C Dobbie under the direction of Prof F J M Stratton) is a complete account of our present knowledge of the spectrum of ionized iron (Fe II) in the region 2150 6228 A

Previously to this work, the classification of the spectrum of Fe II was in the main that of Prof H N Russell, who in 1926 identified some two hundred lines and sixteen terms

The material used by Dr Dobbie was initially that obtained by Prof H F Newall and the late Bryan Cookson and largely extended by many new plates taken by Mr W Moss on the 21 ft Rowland grating of the Solar Physics Observatory, Cambridge and some confirmatory plates in the ultra violet taken by Prof H Dingle at the Imperial College of Science and Technology London In the photographs the lines run from pole to pole of the iron arc and the principal method of picking out lines due to Fe II was to note the lines that were only present at the poles or that were stronger at the poles than in the central part of the arc Dr Dobbie has extended the number of classified lines to some 1 700 and has identified 73 terms involving 218 levels The spectrum presents several peculiar features of interest, in many multiplets the intensities are anomalous and attention is directed especially to the line at 2272 719 A $(a^4D_{\frac{7}{2}}-z^4D_{\frac{7}{2}})$ which has an intensity of 1 only on the scale used, instead of 9 as was to be expected

Several years patient and skilful labour have gone to the production of this achievement For progress in astrophysical research, and in certain branches of physics proper there is great need of the classification of more spectra, and of more detailed or extensive classification of many already partially classified Few in Great Britain devote much attention to this type of work the results are perhaps not very spectacular and in addition to the great consumption of time, considerable skill has to be acquired before the solution of this kind of physical cross word puzzle' can be profitably attempted It is probably only in institutions with a permanent research staff that such work is likely to be done, and we welcome warmly this successful extension of the work of the Solar Physics Observatory

J A C

British Rainfall 1937

the Seventy seventh Annual Volume of the British Rainfall Organization Report on the Distribution of Rain in Space and Time over the British Isles during the Year 1937 as recorded by over 5,500 Observers in Great Britain and Ireland (Air Ministry Meteorological Office M O 427) Pp xx+293 (London H M Stationery Office, 1938) 15s net

THE rainfall of 1937 over the British Isles as a whole was 104 per cent of the average, being 110 in England and Wales 91 in Scotland and 103 in Ireland This distribution was remarkably similar to that of 1936 The main features of the map showing the distribution of the rainfall as a percentage of the average are the large area in the north west of Scotland with less than 80 per cent, and the areas in the south east of England with more than 130 per cent—with more than 150 per cent at Southend Clacton and Boston There was a great excess of rain up to the end of May, greater than in any similar period since 1870, but owing to subsequent dry months the total excess for the year, as indicated above, was small

March and December were outstanding as snowy months Among heavy thunderstorm downpours of the year those of August 13 in the London district and of July 15 over a belt of country stretching from Somerset to Lincolnshire may be cited Approximately 6 inches of rain fell at Boston for the third time since 1930, the other occasions being on July 11, 1932 and August 8, 1931 —a remarkable cluster seeing that the previous greatest fall in a day in that town half a century or so ago was only 3 inches

This year s special articles comprise one by Miss L F Lewis on wind velocity measurements at the level of the rim of the rain gauge at Holyhead, and two by Dr J Glasspoole on the wet and dry periods of 1937 referred to above and on rainfall over the British Isles during the period 1901 1930 in which a comparison is effected with the period 1881–1915 still employed as a standard

Handbuch der Vererbungswissenschaft

Herausgegeben von E Baur und M Hartmann Band 2F Genmutation 1 Allgemeiner Teil Von Hans Stubbe Pp iv + 429 + 1 plate (Berlin Gebruder Borntraeger 1938) 60 gold marks

THIS extensive and thoroughgoing account of gene mutations begins with a historical survey of 43 pages which contains many early records of mutations in plants and animals A full account is given of *Chelidonium majus laciniata* which appeared in 1590, also accounts with photographs, of the Ancon sheep the Manx cat laciniate leaved syringa and alder and many others

The main part of the book is taken up with a record and analysis of the modern work with gene mutations This includes accounts of polygeny heterogeny pleiotropy, dominance etc

The section on the quantitative study of mutation phenomena includes the determination of spontaneous mutation rates, the experimental production of mutations by X rays and other methods with a detailed analysis of the processes by which X ray mutations are produced

The short concluding section on the nature of the gene includes not only a historical background, with the views of Darwin, Naegeli Weismann and de Vries, but also the most recent ideas of gene structure by Koltzoff, Demerec, Muller Wrinch Timoféeff-Ressovsky and others

An extensive bibliography is appended and also a large chart classifying all the known types of somatic and gametic mutations While there are omissions, it will nevertheless be a very useful work of reference man of such a primitive type can surely be considered as obeying the same laws of migration as the higher mammals If now the pre Columbian distribution of the major races (Negro Mediterranean and Alpine) be plotted in a block diagram (Fig 1 *C*) we find a series of *zones and strata* closely resembling the two already charted It is difficult to escape from the conclusion that the centre of Asia is the common cradleland where evolution progressed most actively in the case of primitive man—just as Matthew has shown it progressed most actively here to produce new types of the earlier mammals Indeed we can almost exactly parallel the spread of the rhinoceros from Asia with the spread of the negroes while the spread of the Pleistocene Equidæ is the same as that of Alpine man

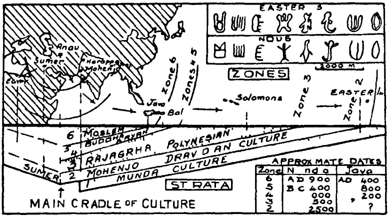

Fig 2

The spread of cultures from India eastward showing the Munda Australoid culture at the bottom covered by Dravidian Polynesian Aryan Buddhist and Moslem strata

In the inset are compared some signs from the Mohenjo and Easter Island scripts All much generalized

The centre of stimulus in Fig 1 *A* was the commercial progress in the city In the case of the mammals and man it was the stimulating climate of south central Asia

We may use as an illustration of the value of the zones and strata concept that complex of races and cultures which characterizes the Indian and Pacific areas I have had the advantage of travelling widely in Eastern Asia and in the Pacific and this has focused my attention on the general principles underlying dispersion in this area It is quite obvious that every widespread characteristic in Polynesia has migrated from west to east—and that any cultural contacts with America can be completely ignored in a general study Let us examine the data in Easter Island—the farthest of these isolated groups from Asia (Fig 2) It is almost 14 000 miles from the Caspian area to Easter Island yet I hope to demonstrate a culture sequence stretching across all this vast expanse

Two remarkable features in Easter Island are the well known stone statues and the undeciphered script incised on wooden tablets There is no reasonable doubt (as the Routledges have shown) that the statues with their bird man decorations are of the same culture complex as is common in the Solomon Islands some six thousand miles to the west (Fig 2) Hevesy and Hunter are satisfied that the script the only one used by Polynesians is connected with the remarkable Mohenjo culture which flourished in the Indus region about 3000 B C It is true that objections have been raised by Métraux that the script was not understood by any living Polynesian and that the tablets of mimosa wood etc are not likely to be many centuries old some indeed being modern in origin I think that these objections are not very relevant Our own alphabet is said to originate from not very similar signs used by miners in Sinai though all the links are not yet clear The question surely is to determine the origins of the remarkable Easter script —and to my mind the Mohenjo theory is plausible and indeed probable Moreover it offers a good illustration of clues which may be furnished by an ecological approach

Let us consider some of the major culture changes in the Indus region Gordon Childe has given data as to the races which have been discovered at Mohenjo Australoids Mediterranean Armenoids and Mongoloids were all present There can be little doubt that the first settlers (before 3000 B C) were the aboriginal Australoids who spoke a Munda language Many members of this zone of peoples are now found pushed to the margin in the East Indies and in Australia It is represented by stratum 1 in Fig 2 The general belief is that the Mohenjo culture was due to the later Mediterranean races who spoke Dravidian languages This constitutes stratum 2 and in my opinion is to be linked with Dixon s Caspian race in the Polynesian area

We have little knowledge of the period 2500 B C 1500 B C in India when the great Aryan migrations overwhelmed North India But it is significant that the earliest stone monuments in India which are found at Rajagrha (Rajgir) near Patna are of a cyclopean character quite unlike the work of the later Aryan builders and rather resemble the mysterious early stone monuments of the Pacific. For example, the Jarasandha monument (of unknown date) is a square truncated pyramid 85 ft. wide and 28 ft. high. It is built of large uncemented blocks of stone 5 or 6 ft. across. It resembles the truncated pyramids and Maræ of Polynesia. I have suggested that this culture complex spread out as stratum 3. The Aryan Sanskrit complex (stratum 4) never reached Polynesia, but was carried to Java and dominated that region for several centuries after 200 B.C. In North India Buddhism (stratum 5) flourished after 500 B.C. and was carried to Java about the eighth or ninth century of our era. It did not displace the older Hindu pantheism—but flourished alongside. Around A.D. 1400 the Moslems (stratum 6) conquered Java and the Indian religions found a refuge in the island of Bali farther east, where they still flourish. It is not, of course, suggested that the Polynesians migrated from India, for they probably lived originally in south-east Asia. But their culture probably followed the same route as that used by the Buddhist and Moslem teachers in historic times.

We may dwell for a few minutes on the recent discoveries in the vicinity of Persia. In Mesopotamia the earliest culture of Sumer is known as 'al Ubaid', and this contained copper tools and is younger than cultures from Susa and the adjacent Persian plateau.

To the north near Nineveh is the Tell Halaff culture with wheeled vehicles but with no metal. This is much older than anything discovered in Sumer near the Persian Gulf. Still older are the lowest cultures of *Samarra* in the same region, where they occur in debris seventy feet below a temple dated about 2450 B.C. Childe has corroborated my statement as to the cradleland of man with his comment that the early cultures of China resemble those of Anau in Turkestan (Fig. 2). It is significant that Zoroaster, the first great religious teacher, lived in this same vital region. Thus we see that the centre of the zones of the *races* of man in Turkestan is also likely to be near the cradle of civilization.

We may use the stage diagram to correlate our scanty knowledge as to the early wave fronts of the Aryan languages. There are three fairly definite subdivisions of Aryan: (1) the early *Kentum* or *K* speeches like Gaelic and Latin; (2) the Intermediate *P* languages like Welsh (with which we may associate Teutonic and Greek for convenience); (3) the later *Satem* languages like Slav and Indian.

Turning to Fig. 3 some idea of our knowledge of the language distribution in Sumerian times is given in the lowest map of the series. At this time Hamitic languages were used by the Pharaohs in Egypt, akin to those still spoken by the Berbers in the Atlas Mountains. Semitic languages characterized Arabia and Syria, as they still do. Sumerian itself has some resemblances to the Altaic, though its affinities are not yet clearly understood. In Europe at this early date there were racial allies

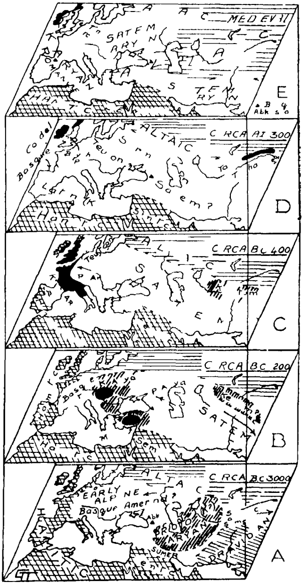

Fig. 3

A STAGE DIAGRAM GIVING A TENTATIVE RECONSTRUCTION OF THE DISTRIBUTION OF EUROPEAN LANGUAGES AT VARIOUS EPOCHS.

Black areas are the Primitive (marginal) *K Aryan* languages. It is suggested that the early Mediterranean race spoke *Hamitic* and that the early Alpines spoke languages akin to *Basque Abkasian* (and Amerind ?). Aryan developed near the Caspian Sea and spread out in waves. The outer ripple (*K*) was akin to *Gaelic*, the second (*P*) akin to *Welsh*. The latest type was the *Satem* group.

of the present day Hamitic speakers—all of Mediterranean race—living in the western regions who probably spoke Hamitic according to Rhys and Jones Central Europe was occupied by early migration of Alpine Brakephs (broadheads) of whose language we know nothing It was almost certainly not Aryan and something akin to Basque seems most likely In view of the important corridor linking Turkestan with China by way of the Tarim Basin I have ventured to suggest that a linguistic kinship between early Chinese (Sinitic) and Sumerian or early Aryan is only to be expected

In the second map (Fig 3 at *B*) for the period around 1200 B C we are on surer ground Vast migrations of Satem speakers had poured into India from Turkestan The Hittites who seem to have spoken an Aryan tongue somewhat akin to the Kentum Group were in control of Anatolia Semitic was now the chief language of Egypt and Mesopotamia

In Central Europe (if we adopt the suggestions of Peake) Kentum languages were spoken in the regions east of the Alps while Brythonic (one of the Intermediate *P* type) was that used by the Cimmerians of the Ukraine and Caucasus areas It seems logical to assume that many Satem speakers still remained in Turkestan and were perhaps allied to the Sarmatian tribes

In the next map (for 400 B C) we see the first great Aryan conquest in the Near East that of the Persians They spoke a Satem language and it is probable that their Sarmatian kin were occupying the European steppes about this time The latter may have been the ancestors of the Slavs who already seem to have settled in the Vistula Basin Meanwhile the marginal *K* speakers (Gaelic etc) had reached Britain and Ireland and still occupied parts of France The distribution of place names in Central and Western Europe clearly shows the migration of waves of Gaelic and Welsh speakers across much of these areas

The conditions some seven centuries later (A D 300) are shown in the next map which deals with Europe during the zenith of the Roman Empire The marginal primitive Aryan language Latin had been carried far and wide so that it later gave rise to Italian French and the other Romance tongues—which are clearly offshoots of the *K* group of Aryan Brythonic (Welsh) was spoken in England South Scotland and Wales at this time and probably in parts of the continent besides Brittany Possibly some Hamitic dialects still persisted in the Scottish Highlands as suggested by some of the Ogam inscriptions Gaelic (a *K* language) was spoken in Ireland and in most of Northern Scotland

Of great interest is the discovery that a Kentum language called Tocharese was still in use north of the Tarim Basin in Central Asia about this time (Fig 3 at *D*) Tocharese seems however to have some affinities with the Intermediate and Satem groups also Hence it may well be fairly close to the *generalized* Aryan ancestor from which all three groups of Aryan have descended It is suggested in the diagrams that this Kentum speech had been continuously used east of Turkestan since early Aryan times

The medieval distribution of languages and of the three subdivisions of Aryan is shown in the top map To day Gaelic is almost the sole representative of a little altered primitive Aryan speech —though the much evolved derivatives of primitive Latin are still very important languages (Jespersen 1894) Hamitic has died out in Europe Altaic has encroached in Hungary and Finland and displaced Hittite and Greek in Anatolia Semitic has driven out Hamitic in much of North Africa Satem Aryan in the form of Russian is in turn displacing Altaic throughout much of the U S S R

The conclusion to be drawn from this tentative geographical approach to the Aryan problem is that the waves of language have spread from Turkestan towards India Persia and Europe There seems to be no support for the origin of Aryan in the German or Lithuanian regions a theory which has been strongly upheld by a number of notable continental philologists

During the twentieth century the trend of geography has been away from the belief of Ritter in providential control and from environmental control as expounded by Ratzel towards the possibilism concept of Vidal de la Blache and his school The latter geographers picture any particular region as offering almost innumerable possibilities of exploitation to man Our material evolution in their opinion is essentially a matter of our own choice depending on which of the possibilities *we* choose I have come to a different conclusion no doubt primarily owing to my experience in pioneer countries like Australia and Canada where the possibilities offered by Nature to man are more meagre than in Great Britain or the United States Indeed of these three schools which we may label the theocratic the geocratic and the we ocratic I definitely belong to the second However I propose to illustrate by the correlative method first in a pioneer country like Canada and secondly in the old established culture complex of Europe that man is not really a free agent—but definitely a product of his environment

A generalized economic map about 1750 shows that fish farms and fur had expanded to Saskatchewan Some sixty years later by 1810 farming had spread approximately to Detroit while Mackenzie was exploiting for furs the river basin named after him By 1870 mining was becoming of some importance and gold silver and iron mines were being exploited both near the St Lawrence and on the Fraser River Still more important Selkirk had more than fifty years earlier settled his isolated band of farmers on the silts of Lake Agassiz in the heart of the continent About 1880 the modern migration to the wheat fields of the prairies began In 1930 the whole north of the Dominion is being exploited not only for furs but also for metal mines the latter in part by air transport Agriculture has covered most of the inland prairies and will extend north (and into the clay belt) Manufactures have spread along the St Lawrence from Montreal to Ottawa and Windsor in large part owing to the bountiful water power

But while there have been these striking advances and changes in the type of industry man has not really been a free agent His advance from fur hunting to wheat growing is only possible where rain and sun and soil are satisfactory *All* the fur country cannot be utilized for wheat even if man so wishes Using a foreign example we shall never see hydro electric power or coalfields leading to the development of factories in that half of the southern continent known as empty Australia however much man may wish to replace the sparsest of pastoral occupation by better paying industries On the other hand it seems clear to me that in the future the immense coal resources of Alberta must inevitably be utilized as the more accessible coalfields are used up elsewhere Man may very probably some day choose (as the possibilist school would say) to give up ranching in the drier parts of Alberta and turn to manufacturing based on the almost inexhaustible coal But he is none the less controlled by his environment

Exaggerating somewhat I feel that man s part in the programme of a country s evolution is not unlike that of a traffic policeman He can accelerate slow or halt the traffic but he does not alter its direction This stop and go determinism has no supporters among the historians and not many even among geographers But it expresses something of the conclusions that I have arrived at from my lengthy study of the difficult environments of Australia and Canada

Sense Perception and the Evolution of Colour and Pattern

THE recent symposium* and discussion on Sense Perception and the Evolution of Colour and Pattern held under the auspices of Section D (Zoology) of the British Association at Cambridge directs attention to a field of inquiry where the artist the naturalist and the psychologist may meet

In the interrelationships between animals of the same or of different species—as between predator and prey between rival males or the opposite sexes between parent and offspring or between members of the group—characters which exert their influence from a distance by sound by sight or scent and the sensory equipment with which such stimuli are perceived each play a vital part

The study of such characters to which Dr J S Huxley has applied the term allæsthetic[1] involves various questions of wide interest How far has the evolution of vision gone parallel with the development of characters serving as visual stimuli ? What is the functional significance of the elaborately evolved stimulating equipment on one hand and of the highly specialized sensory apparatus possessed for its appreciation by other animals ?

The phenomena may be approached from various points of view the nature of the allæsthetic characters themselves the public in relation to which they have evolved the ecological significance of the relationship between the organisms concerned Broadly speaking the phenomena of adaptive coloration fall into three main classes according to the visible results achieved—namely concealment advertisement and disguise The biological function of such elusive attractive or deceptive features varies widely according to circumstances Through reduced visibility they may facilitate the capture of food or escape from the aggressor Through increased conspicuousness they may serve as a warning to enemies or a threat to rivals as a courtship display or a recognition mark Through deceptive or mimetic effects they may mislead the observer as to an animal s whereabouts attitude or identity

Studies of adaptive coloration and visual perception have shown that there exists a close correlation between allæsthetic characters and the sensory equipment of the animals towards which they are directed and in relation to which they have evolved Such characters therefore assume a new interest in the indirect light they throw upon questions of comparative psychology and sense perception On these grounds it may be concluded for example that the rarity of bright colours among mammals below the primates is evidence of colour blind vision in these forms while conversely the varied and saturated hues exhibited by different fishes and birds and by entomophilous flowers postulates a colour sense in the vertebrates and insects concerned Such conclusions are borne out by the evidence of experiments upon colour vision in these groups

---

* Speakers at the symposium were Dr J S Huxley Dr H B Cott, Mr D Lack and Mr L H Birkill

The optical properties of the structures displayed also permit deductions as to the differential reception of light rays by different animals The limits of the visible spectrum for man and for animals do not necessarily coincide Bees for example are blind to red but have a range of colour vision extending far into the ultra violet and it is significant that many bee flowers reflect ultra violet light On the other hand red is an efficient stimulant to diurnal birds and it is more than a coincidence that red finds a dominant place in bird advertisements whether their function is attractive—in the form of ornithophilous flowers or fruit or repellent—in the shape of aposematic insect prey

Allæsthetic characters may also throw light on higher faculties It is to be noted that where visibility from a distance is required as in characters subserving the functions of warning threat or recognition crude colours and simple patterns have been developed On the other hand characters which are employed solely or mainly in epigamic display and used at close range like the plumes of birds of paradise tend to be detailed delicate and beautiful rather than merely conspicuous advertisements and as such they suggest powers of æsthetic appreciation in the species which display them Similarly in the field of concealment the extraordinary degree of perfection attained by many insects and other animals in their special resemblance to bark lichen leaves and other objects—achieved by the combined effect of colour pattern and posture—almost presupposes in birds (their natural enemies) those exceptional powers of visual acuity and form perception which on other grounds we know them to possess

Viewing the relationship in a somewhat different light it is becoming increasingly clear from an investigation of their nature and occurrence that the so called adaptive appearances are in fact to be interpreted in terms of visual perception—that their end is an appeal to the eye Thus in the sphere of concealment it is significant that the particular arrangements of colour and pattern which for optical reasons are those best adapted to reduce visibility and which include special optical devices for obliterating the visible characters upon which recognition depends—such as differences of colour of light and shade continuity of surface outline and shadow—are those actually employed in the coloration of different cryptic species Moreover various patterns especially those of the coincident disruptive type[2] contradict and frequently cut right across separate structural elements—underlying anatomical features becoming subordinate to the illusionary appearance superimposed upon them Further such colour schemes are largely independent not only of anatomy but also of affinity—a point which was effectively stressed by Sir Edward Poulton forty years ago[3] Equally convincing is the evidence to be derived from the general habits resting attitudes and special reactions of cryptic sematic or mimetic animals when considered in relation to their conditions of life

Modern knowledge demands considerable modification of Darwin s theory of sexual selection While the Darwinian doctrine almost confined the effects of epigamic display to the sphere of psychology—to the female choice of mates—and as such was applicable only to displays of unmated males before pairing up recent research has pointed on one hand to the prevalence of displays by one or both sexes during later phases of the breeding cycle and on the other to the far reaching physiological effects of these and other visual phenomena in stimulating and regulating reproductive functions

It is now recognized that displays by one or by both sexes subsequent to pairing up and leading to coition have a profound influence in serving to promote ovulation or to synchronize physiological rhythms connected with the readiness to mate[4,5,6] These effects depend not merely upon epigamic display they may be decided by such characters as the population density of a breeding colony[7] the presence of correct nesting material or of a suitable nesting site[9] On the other hand mutual displays during the post nuptial period in such birds as grebes and divers where both sexes share family duties seem to serve as an emotional bond between the pair throughout the breeding season[10]

A distinction is not easily drawn between characters evolved in relation to epigamic display and those serving other functions involving conspicuousness Many display characters whether of colour or posture have no direct bearing upon courtship In some species such as the Bishop bird (*Euplectes h hordeacea*) the display apparently has to do solely with territorial claims[11] Or again the same conspicuous characters may in different circumstances take on different functions as of recognition or warning threat or courtship Thus the ruff of the great crested grebe is employed in different ways for threat against rivals of the same sex and for display towards members of the opposite sex The complex nature of the phenomena has been demonstrated by Mr David Lack, who has shown that the robin, while able to distinguish its mate from other individuals, will yet sometimes attack the headless remains of a stuffed specimen in which little more than the breast is visible

In conclusion, it is to be noted that the study of all æsthetic characters is not devoid of application to everyday matters Just as the form of fishes and birds has in the past been invoked to assist the marine architect and the aircraft designer, so, it may be hoped, will the coloration of cryptic animals read a much needed lesson on the principles and practice of concealment to those responsible for the applications of camouflage in time of war

Obituary Notices

Cavaliere Filippo De Filippi, Hon. K.C.I.E.

Cavaliere Filippo De Filippi, who died at his home near Florence on September 23 at the age of sixty nine years, is probably best known in England as the leader of the Italian Scientific Expedition to the Himalayas, Karakorum and Chinese Turkestan in 1913–14

This Expedition, probably the largest and best equipped that has ever visited Central Asia, was the conception of, and entirely organized by, De Filippi His basic idea was the connexion of the gravimetrical surveys of India and Russian Turkestan by a chain of stations across the mountain ranges—the Himalayas, Karakorum and Kuen Lun—which separate them This involved the accurate determination of the astronomical and geodetic co ordinates of the stations, necessitating the use of instruments and methods of much greater accuracy than those normally used for survey work in such areas The use of wireless time signals for the determination of the differences in longitude was the pioneer experiment in this method, and was highly successful The anomalies of gravity deduced from the determinations made by the Expedition confirm the general conclusions drawn from those made by the Survey of India and the Russian Geodetic Service

Complete sets of magnetic observations were made at each gravity station, and in addition, throughout the period November 1913–August 1914, full meteorological records were taken three times daily These were extended to hourly readings from 6 a m to 8 p m during June 1914 and for the whole 24 hours during July, during which time the observers were on the Depsang Plateau Observations for solar radiation and of the velocity and direction of the higher air currents were also made when weather permitted

The geology of the whole area traversed was thoroughly examined by the two eminent geologists who accompanied the Expedition, and at the same time anthropological and ethnological studies were made. A topographical survey of the country was also carried out and the very interesting geographical discovery made that the Rimu glacier divided on the Central Asian watershed The main branch forms the source of the Shyok the largest tributary of the Indus River, while a large but subsidiary one, extending to the north, is the source of the Yarkand River, which eventually loses itself in the deserts of Central Asia

Dr De Filippi was responsible for all the preliminary organization of the Expedition, and during it, in addition to his work as leader and medical officer, took charge of the transport and supply work, thus leaving the scientific officers free to devote their whole energies to their own special work All his arrangements worked without a hitch, and the success of the Expedition was undoubtedly due to his great forethought and organizing abilities, and his tact in handling all sorts and conditions of men He had a most charming manner and made friends with every one he met, who must all deplore his death

The results of the Expedition have been published in Italian in seventeen large volumes, but only the general narrative has been translated into English

Dr Josef Rosenthal

Dr Josef Rosenthal, formerly of Munich, died at Hampstead on August 7 last As a young physicist, Rosenthal was one of the first to recognize the importance of Röntgen s discovery to medicine, and he devoted his life to the development of the X ray tube, with special regard to its medical use

Rosenthal's first experiments were reported to the Deutscher Naturforscher und Aerzte Tag in Braunschweig in 1897 in a paper "Ueber Röntgenbilder" In the same year, he began to work with H Rieder, the medical radiologist, and this collaboration, which lasted for more than thirty years, led to many important results One of Rosenthal s constant aims was to reduce the exposure time necessary for X-ray photography This made possible two of the outstanding results of his work with Rieder, namely, the first X ray photograph of the human thorax in a living subject (1899 , later frequently improved), and the first successful attempt at X ray cinematography of the movements of the human stomach (1909) Jointly with Rieder, Rosenthal was editor of the first Lehrbuch der Röntgenkunde (first edition 1913 , second edition 1924)

In later years, Rosenthal took an active interest in the development of the Deutsches Museum in Munich, especially in its Department of Radiology, an activity which found its official recognition on the occasion of the laying of the foundation stone of the new Museum, in 1928, when he was awarded the 'Goldene Ring of the Museum A popular lecture, given in the Museum, entitled 'Das Jahrhundert der Strahlen appeared as a pamphlet in 1930

We regret to announce the following deaths

Sir Henry Fowler K B E , formerly chief mechanical engineer of the London, Midland and Scottish Railway on October 16, aged sixty eight years

Dr Willis R Gregg, chief of the United States Weather Bureau known for his work in aeronautical meteorology, on September 14, aged fifty eight years

Dr Thomas C Hebb, professor of physics in the University of British Columbia on August 13, aged fifty nine years

Prof Maurice d Ocagne, free member of the Paris Academy of Sciences known for his work on the application of geometrical methods to the calculus, and author of the Traité de Nomographie (1919) on September 23 aged seventy six years

---

News and Views

Sir Daniel Hall, K C B , F R S

The impending retirement of Sir Daniel Hall from the directorship of the John Innes Horticultural Institution will presumably close his very long connexion with agricultural administration and research From the time when he was the first principal of the South Eastern Agricultural College Wye, and throughout his directorship of the Rothamsted Experimental Station his tenure of office as principal scientific adviser to the Ministry of Agriculture and Fisheries and lately as director of the John Innes Institution, Sir Daniel has impressed all by his knowledge, his sound judgment and tact, and not least by his great ability as a writer and speaker Like the late Lord Ernle, and his successor at Rothamsted Sir Daniel excels in the art of exposition, and British scientific agriculture has indeed been fortunate in commanding the services of men of this type Now that he has passed the stage when, in the pursuit of duty, it is no longer necessary to "rise earlier than virtue and go to bed later than vice", we hope that Sir Daniel will find occasion to continue his great interest in the social contacts of science , but no one will grudge him time to devote to oriental art and other "digressions of a man of science" Science needs men like him who can write and speak, as well as think and do in order that its voice may be heard amidst the disharmonies of a world torn by political turmoil and social strife

International Study of African Problems

The Volta Foundation Congress, which met in Rome at the beginning of October under the auspices of the Italian Royal Academy for the discussion of questions relating to Africa, was attended by delegates from fourteen European countries, including representatives of Great Britain and Germany The delegates appear from the reports of the proceedings to have appreciated to the full both the joint responsibility of the nations of Europe for the future development of Africa, which was stressed by Prof Orestano in his address at the opening of the Congress, and the desirability of international co operation on a broad basis in the study of conditions which is a necessary preliminary in the approach to the problems, upon the solution of which advancement of Africa and her peoples must depend Among the topics discussed on these lines were such matters as tropical diseases, native education, European settlement, anthropological studies, communications, and the like In view of the attitude of the delegates on these matters, it is not surprising that in the final session strong expression was given to the opinion that some permanent organization should be formed for the promotion of international co operation in further inquiry , while it was also urged that nations other than those at present interested directly in Africa, should be invited to participate in the interests of civilization at large While any proposal is welcome which aims at promoting study of the problems of Africa as a whole, and seeks to attract collaboration from as wide a field as possible, it may not be out of place to recall that there are already in existence international organizations, which in certain fields are doing excellent work, and are capable of ready extension,were funds available It would, however, be premature to offer comment before the present proposal takes more definite shape

Boundaries for University Teachers

Any action which affects the positions of members of scientific staffs of universities or similar institutions concerned with the promotion of natural knowledge, or restricts fields of research, or is in conflict with the spirit of internationalism in science, commands the attention of scientific workers everywhere It is on this account, and as an indication of the restrictions imposed upon the movements of university teachers by State authority, that we print the following translation of a decree issued for information and action in August last in Vienna by the Ministry for International and Cultural Affairs

Invitations to positions in foreign countries issued to Austrian university teachers who are non Aryan married to a non Aryan or politically unreliable

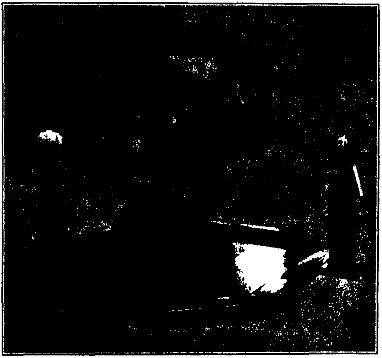
To the Rectors of the Austrian universities and to the Dean of the Theological Faculty in Salzburg also to the Academies of Fine Arts and to the Rector of the World Trade College

At the instance of the Minister of Education the attention of the Rectors and Dean is drawn to the fact that the decree of April 23rd 1938 Zl 12822 forbidding all university teachers to negotiate about a call to a university outside the German Empire without previously obtaining the consent of the Ministry of Education applies also to university teachers who have retired and to others who for other reasons have ceased to occupy their positions

Should the Rectors or Dean learn of an Austrian university teacher, retired or dismissed who is non Aryan, married to a non Aryan or politically unreliable who is trying to obtain a call to a foreign university or already preparing to occupy such a position, they must report the case here at once —The State Commissar Plattner

A Geological Globe

A TERRESTRIAL globe, believed to be the largest yet prepared to show both orographical detail and the distribution of the main geological formations was formally installed in the Geological Museum at South Kensington on October 10 by Sir Frank Smith secretary of the Department of Scientific and Industrial Research The globe was modelled by Mr C d O Pilkington Jackson, of Edinburgh, from data compiled by Mr D L Linton It consists of a sphere of fibrous plaster, 5 ft 11 in in diameter, strengthened internally by steel stays arranged around a steel tube which forms an axis from pole to pole and is tilted at 23½° from the vertical The globe is supported by a steel spindle which is electrically rotated at a rate of one revolution in 2½ minutes The linear scale is approximately 1 7,000,000, and relief is exaggerated twenty times The geological colouring has been carried out in the Museum by Mr C Keefe under the direction of Mr A J Butler The colour scheme is designed to demonstrate the broad outlines of the geological structure of the continents in a fashion sufficiently simple to appeal to the non geological visitor and at the same time to reveal on closer inspection sufficient detail to render the globe of special use to teachers and students of geology and geography Six distinct colours are used to indicate the sedimentary deposits of the geological eras and the systems formed during each era are distinguished by graduated shades of the appropriate colour the lightest shade represents the newest system the darkest represents the oldest A system of stipples is used to show the age limits of rock groups which cannot be divided into systems Igneous rocks appear in scarlet and orange and ice caps rivers and lakes are also marked Provision is made for corrections and additions as new information comes to light The geological globe bears no lettering or symbols Two small physical globes which are mounted near it act as geographical indexes, and a sphere some 19 inches in diameter and 60 yards away demonstrates the relative size and distance of the moon



GEOLOGICAL GLOBE AT THE GEOLOGICAL MUSEUM SOUTH KENSINGTON

Decibels and Phons

WE owe it largely to the public interest in the abatement of noise that two hitherto unfamiliar, but now international, units—the decibel and the phon—have come into common use The decibel, which arrived from America via the telephone engineer represents approximately a 5/4 geometrical increase in acoustical energy or intensity This forms the basis of a logarithmic scale of energy levels which advance by increments of one decibel, starting from a zero which is arbitrarily fixed near the threshold of hearing The phon which was imported from Germany, is the unit of loudness or, more precisely, of equivalent loudness It is derived through the medium of a pure tone of 1000 cycles per second which is set up as a standard of reference Where the reference tone is stimulated by an energy level equal to n decibels above the zero its loudness level is declared to be n phons If further the reference tone has been regulated so that as heard by an average ear under specified conditions its loudness is assessed as equalling that of some other sound or noise then the equivalent loudness of the latter is also declared to be n phons

In this way we overcome the difficulty that energy and loudness do not necessarily keep in step when the frequency is changed and so through the intermediary of a device akin to the standard candle of the photometrician we can link the phon level with the decibel level which latter is measurable by physical instruments called noise meters Mr Ll S Lloyd feeling that all this is too difficult for a musician to comprehend has based a simple explanation of it on the parallelism of the decibel to the musical interval of a major third (5/4) and has published it in an attractively written pamphlet (Decibels and Phons A Musical Analogy London Oxford University Press 1s 6d net) The major third can naturally serve as an increment to build up a scale of pitch which is of course no less a logarithmic scale than any other musical scale such as that of the more familiar octave To interpret pitch as intensity apparently comes naturally to a race of selectively gifted monsters whom the author amusingly creates for his purpose Even those to whom the analogy may seem somewhat circuitous will find the treatment pleasant reading while there will no doubt be others besides monsters and musicians to whom Mr Lloyd's method of approach will commend itself

Science and the Welfare of Animals

A Scientific Investigations Committee has been formed by ULAWS (University of London Animal Welfare Society) which is in the course of being incorporated into the newly formed Universities Federation for Animal Welfare The committee will concern itself with the acquisition of knowledge calculated to benefit animals in their own interests as distinct from the interests of the human species Its functions will be to define problems for inquiry to advise as to the allocation of funds for the purpose and to collect and communicate any new knowledge which may be of value for increasing the well being or diminishing the sufferings of animals A small grant has been made in aid of an ecological investigation relevant to the control of wild populations which is frequently carried out by methods considered by many to be inhumane Among the other topics in which the committee is interested are the widespread failure to utilize existing knowledge of dietetic principles the problem of bait poisons the destruction of sea birds by oil waste and the use of an electric goad as a substitute for the stick in droving cattle The members of the committee are Capt C W Hume (chairman) Dr S Graham Brade Birks (hon secretary) Dr Paul Haas Mr H R Hewer and Dr W R Wooldridge Men of science who are in sympathy with the objects of the committee are invited to communicate with Dr S Graham Brade Birks South Eastern Agricultural College Wye Kent

London Scientific Film Society

The proposed formation of a scientific film society which would give shows of scientific documentary films to its members and their guests was announced in Nature of June 4 Such a society has now been formed under the name of the London Scientific Film Society and its inaugural meeting was held on October 14 at the Conway Hall At the meeting Mr L V Chilton explained how the formation of the Society was a direct result of the work of the Association of Scientific Workers on scientific films One of the functions of the Association is the promotion of a proper understanding of science by the general public and of what science can do for society the Association is therefore interested in the teaching of science and in the proper treatment of science on the screen Mr Arthur Elton referred to the London Film Society which was formed eleven years ago and has had a broadening influence on the æsthetic film He said that if the London Scientific Film Society is to be successful it must reveal to the public both the achievements of science and the potentialities of the scientific documentary film Such a society can do much to raise the standard of scientific accuracy of the films shown in public cinemas and also to increase the number of scientific films shown The first show of the Society will be held at 2 30 p m on Sunday November 13 at the Academy Cinema Particulars of the Society and forms of application for membership can be obtained from the Secretary at 28 Hogarth Road S W 5

Faiths and World Fellowship

The World Congress of Faiths was founded several years ago by Sir Francis Younghusband to promote a spirit of fellowship among mankind through religion The object of the organization is to awaken and develop a world loyalty while allowing full play for the diversity of men nations and faiths There have been three congresses in London Oxford and Cambridge respectively in 1936 1937 and 1938 and the proceedings have been published in volumes obtainable from the Secretary World Congress of Faiths 36 Victoria Street London S W 1 Owing to the tension in the international situation the committee of the Congress has decided to postpone the holding of the next congress at the American University Beirut and arrangements are being made for the 1939 Congress to be held in Paris A meeting will be held in the Kensington Town Hall at 8 30 p m on October 31, at which Lord Gorell will take the chair and Hindu Jewish Muslim and Christian speakers will deliver addresses on The Crisis through Faiths to Fellowship

Air-Raid Precautions

Two publications recently issued by the British Steelwork Association, Steel House, Tothill Street London, S W 1, are of permanent value, although happily the international crisis is over The first of these, entitled "Steel for A R P", suggests ways in which standardized steel products can be used for air raid protection One of these standard products is corrugated steel sheets and it can be used for overhead cover Similarly the steel arches used to support the roadways of collieries are applicable to construct shelters in basements, railway embankments and cuttings The booklet dwells on the advantages of steel frame construction from the point of view of its ability to resist explosive shock These frames withstand stresses in any direction A frame is not dependent for its strength upon the walls, and it can easily be repaired Various types of wall and floor construction are described and so also are the customary brick panels The latter are considered to be able to deal with blast and splinters when well tied up to the supporting structure The use of pressed steel window sub frames can increase their strength In existing buildings the most appropriate site for a shelter is the basement, and some useful hints are given of the best way of using existing steel products to strengthen it The second book deals with the Everyman trench shelter, and will be of interest to many It describes with the help of drawings how a householder can build a shelter capable of holding four persons and sufficient to afford protection against blast and splinters For the roof curved sheets five feet long are used and standard flat corrugated iron sheets six feet long for lining the walls A bill of the quantities required is given It has been suggested that now that time is not important, there will be many who will consider it worth while to build such a shelter in their leisure hours As the roof will be covered with the excavated soil, it might be sown or planted in such a way that the amenities of the garden would not greatly suffer

Protecting Airships Against Fire

SOME of the problems that have to be solved when protecting airships against fire, due to electric sparks in the neighbourhood of free hydrogen, are discussed in an article in *The Times* of October 18 The latest German airship, the LZ 130, which inherits the name of *Graf Zeppelin*, is denied the use of helium, and so uses hydrogen gas Dr Hugo Eckener and his colleagues are engaged in experiments during flight to test a project for making the potential of the static electricity within the airship frame equal to that of the electrical field outside The experiments are based on the use of a new instrument which records the nature and intensity of the static charge in the airship and of the electrical conditions in the atmosphere surrounding the hull Its function appears to be that of warning the captain of conditions in which it would be dangerous to 'valve gas or to have an appreciable leak of gas There is little danger even when the aircraft passes through a field of opposite charge, unless there is a gap in the bonded structure across which a spark may jump If the new instrument works satisfactorily, it would give a warning when the conditions were dangerous and special precautions could be taken It would enable the captain to see whether or not it was desirable to earth a positive charge when in the neighbourhood of a negatively charged cloud Such stations have been made in miniature and experiments on a small scale have been carried out Experiments will shortly be made in full scale under natural conditions

Excavation of a Neolithic Barrow in Kent

SIR EDMUND DAVIS's excavation of Julaber's Grave, Chilham Hill Kent, under the direction of Mr R F Jesup, in continuation of the investigations of 1937, after a brief interruption during the recent crisis, owing to the absence of the director, has been brought to a close, after being carried to a point at which it was proved conclusively that the barrow is of neolithic age Reports of the result of the excavation (*The Times*, October 1 and 12), state that a polished flint axe about six inches long, with flattened sides, curved edge and made of creamy white flint, was found in a layer at a depth of four feet six inches, in which were also rough sherds, a human tooth, pointing to a burial, and a number of flint flakes, such as are found only in the area of the mound in the adjacent cultivated soil Traces of charcoal in the core of the mound, particularly in the neolithic turf layer, support the theory that the area was cleared by burning The polished flint axe which substantiates the neolithic dating of the mound, is of Scandinavian type, and, it is suggested, allies the mound with the megalith builders of the Baltic, rather than with the long barrow peoples of Dorset and Wiltshire It is certainly significant that, as the report points out, Julaber's Grave in relation to the other long barrows of Britain, stands in a position of isolation Further investigation of the Roman burial containing the skeletal remains of three individuals which was found in 1937, has revealed a remarkable, and at first sight puzzling, construction of flint at the southern end of the grave This has proved to cover the burial of a man and a horse The head of the horse, however, is missing, and the usual platter and bowl are in fragments Apparently the burial had been disturbed, while the flint structure had been placed there to prevent the remains, buried in the side of the mound, from slipping into the ditch

Reduction of Maternal Mortality

THE Minister of Health has communicated with local supervising authorities on methods that may be adopted in order to secure that the best obstetric aid is available to expectant mothers on occasions when midwives have to call in a doctor (Ministry of Health Circular 1705 H M Stationery Office 1*d* net) The recommendations are that a panel of doctors who will be available for this service should be drawn up for the area of each authority, and that a small advisory committee should be set up to advise the authority in regard to the operation of the arrangements and on any alteration that may be deemed necessary in order to secure and maintain a high standard of obstetric practice It is hoped that the adoption of arrangements on those lines will help in reducing the present maternal mortality rate

Conference of the National Union of Teachers

A BOOKLET has been issued containing eight of the addresses delivered at sectional meetings of the Annual Conference of the National Union of Teachers held in Margate in June last (London National Union of Teachers, 6*d* net) Exemptions and Beneficial Employment , in connexion with the Factory Act, 1937, which has just come into operation was the subject of addresses by Major Evan Davies Mrs Alderman Wainwright and Mr F A Ring, who all foresee considerable difficulties for the authorities and administrators who have been given the task of working the Act The subject of handicraft in schools was dealt with by Mr F Potter, who considers that the prestige of handicrafts and of handicraft teachers never stood higher and continues to increase He expressed the hope that, in the future, room would be found for promotion to headships in the newer senior schools of the really educated and skilled craftsman

London Lectures for Teachers

THE L C C *Handbook for 1938 39 of lectures* and classes for teachers gives particulars of 114 courses distributed over a wide field Nearly half (52) relate to art and crafts music and physical education, 19 are listed under pedagogy and 7 under science Among what may be called the star turns are lectures on food production by Sir John Russell on recent advances in physics by Prof J D Cockroft and Prof F K Rideal on vitamins, hormones and stimulating substances by Dr J Needham and on astronomy by Sir Arthur Eddington There are three courses which should prove useful on how to make use of museums (British, Victoria and Albert and London) Four deal with the important, but too often neglected, subjects of speech training, speech therapy and backwardness in reading Another often neglected subject will be dealt with under the title Thinking and Writing by Mr R W Jepson at Mercers School on lines designed to help in the training of children of 11–14 years of age to use language as a medium for clear and exact thought and expression—to understand its structure and working and the meanings it conveys, to realize its potentialities for enlightenment and confusion, and to apply the knowledge thus gained to their own writing The equally neglected science and art of cookery find no place in the programme except by implication in the syllabus of a course on domestic subjects

Australian Journal cf Science

THE first number of the *Australian Journal of Science* has recently been issued This journal is published by the Australian National Research Council under the auspices of the Australian and New Zealand Association for the Advancement of Science, and six numbers will appear each year Scientific work in Australia has developed greatly in recent years, and the need for a means of publishing short advance summaries of research has become more and more apparent The new journal is designed to satisfy this need and also, in line with other well known scientific journals, to publish reviews, news and views, reports of proceedings of various scientific institutes and correspondence The first number now to hand augurs well for the success of the project The substance of the inaugural lecture by Prof Eric Ashby, newly appointed professor of botany in the University of Sydney, on "The Place of Biology in Australian Education" is purposely provocative and should be read with interest and profit by all biologists, but especially by those responsible in some way or another for the teaching of biology in Australia Sir Douglas Mawson has an interesting short article on research in the antarctic *Australian Science Abstracts* are in future to be incorporated in the *Australian Journal of Science* as a supplement Subscription for the *Journal* is 12*s* for one year Further information can be obtained from the Australian National Research Council, Science House, 157–161 Gloucester Street, Sydney N S W

Institution of Civil Engineers Awards

THE following awards of the Institution of Civil Engineers have been made *for session 1937–38* *Telford Premiums* to Sir George Lee, M G J McHaffie, jointly to W C Parker and Hubert Clarke jointly to William Hudson and J K Hunter, George Ellson, jointly to F J Buckton and H J Fereday R W Mountain W A Tookey, F C Vokes, Prof A H Gibson, J F Hay, Frank Fancutt, T H Seaton , *Coopers Hill War Memorial Prize* to William Hawthorne and F H Williams (jointly) , *Trevithick Premium* to R G Knight , *Manby Premium* to Dr H J Gough and W A Wood (jointly) , *Indian Premium* to M R Atkins and D H Remfry (jointly) For papers published in the *Journal* without oral discussion *Telford Premiums* to Prof F C Lea and J G Whitman (jointly) , Dr C F Colebrook and Prof C M White (jointly), Herbert Addison, Thomas Donkin , *Trevithick Premium* to G C Blofield *Crampton Prizes* to J R Daymond, Serge Leliavsky For students papers read in London or at meetings of local associations *James Forrest Medal and a Miller Prize* to John Hayes , *Miller Prizes* to I S Chisholm, A R Collins, A L Arnold, F F Humphries, Jack Mercer, J M P Hooley

Australian and New Zealand Association

THE twenty-fourth meeting of the Australian and New Zealand Association for the Advancement of Science is to be held at Canberra on January 11–18, 1939, under the presidency of Prof Ernest Scott, emeritus professor of history in the University of Melbourne This meeting is regarded as the jubilee meeting of the Association, the first meeting having been held in Sydney in August 1888 under the presidency of the late Mr H C Russell Six men of science from Great Britain have accepted invitations to attend this meeting they are Prof F T Brooks Sir John Flett, Dr Julian Huxley, Sir John Russell, Dr N V Sidgwick and Mr H G Wells It is hoped that the practice thus introduced of welcoming a group of scientific workers from overseas will be continued at all future biennial meetings The presidents of the sections are as follows Section A

(Astronomy, Mathematics and Physics), Prof T Parnell, Section B (Chemistry) W Russell Grimwade, Section C (Geology) Prof R Speight Section D (Zoology), E J Goddard, Section E (History) Prof S H Roberts, Section F (Anthropology) F F Williams, Section G (Economics Statistics and Social Science) L G Melville Section H (Engineering and Architecture) Sir Henry Barraclough Section I (Medical Science and National Health) Dr E Sydney Morris, Section J (Education, Psychology and Philosophy) J R Darling Section K (Agriculture and Forestry) Dr W I Waterhouse Section L (Veterinary Science) Dr L B Bull Section M (Botany) Prof J G Wood Section N (Physiology) Prof W J Young Section O (Pharmaceutical Science) Dr E M Watson Section P (Geography and Oceanography) G A V Stanley

Announcements

THE Duke of Kent will preside at a meeting called by the Duke of Devonshire (chairman of the Society for Extending the Rothamsted Experiments) and the Earl of Radnor (chairman of the managing committee of the Station) to consider arrangements for celebrating the approaching centenary of the Rothamsted Experimental Station at Harpenden The meeting will be held in the rooms of the Royal Society on November 1 at 3 p m

DR ROBERT COURRIER professor of medicine at the Algiers Faculty of Medicine, has been made professor of experimental morphology and endocrinology at the Collège de France

THE Twelfth Annual Radiological Congress and Exhibition will be held on December 7 9 at the Central Hall Westminster London S W 1 The nineteenth Mackenzie Davidson Memorial Lecture will be given by Dr G Shearer and the twenty first Silvanus Thompson Memorial Lecture by Dr R Ledoux Lebard

A COURSE of ten lectures and demonstrations on tropical hygiene for men and women outside the medical profession proceeding to the tropics, will be given by Mr H H Clay Prof R T Leiper and Sir Malcolm Watson on November 28 December 9 at the London School of Hygiene and Tropical Medicine Further information can be obtained from the Secretary, London School of Hygiene and Tropical Medicine, Keppel Street Gower Street W C 1

THREE meetings of the Association of Scientific Workers open to the public have recently been announced On October 25 Prof A Ferguson, Prof H Levy and others will speak on 'Scientists and War, on November 3, Prof J D Bernal will speak on The Finance of Scientific Research', and on November 23, Prof Winifred Cullis will discuss "The Film in Education Further information can be obtained from the Secretary at Kelvin House, 28 Hogarth Road, South Kensington, S W 5

A CONFERENCE on Child Guidance will be held at the Royal Sanitary Institute on November 17 at 2 30 p m under the chairmanship of Sir Henry Brackenbury The discussion on What can local authorities do for the maladjusted child? will be opened by Dr C J C Burns Special School medical officer and director of child guidance Birmingham Further information can be obtained from the Secretary Royal Sanitary Institute 90 Buckingham Palace Road S W 1

THE programme of the Sex Education Society for 1938–39 includes lectures on sex in prison, by Mr Wilfred Macartney on masturbation, by Dr Wilhelm Stekel on female homosexuality, by Dr Adrian Stephens on sex and the adolescent by Mr A S Neill and on problems arising out of the new divorce law by Mrs M L Seaton Tiedemann Further information may be had from the Secretary 127 Harley Street W 1

THE sixty seventh annual meeting of the American Public Health Association will be held at Kansas City Mo on October 25 28 There will be ten sections devoted respectively to health officers laboratories vital statistics public health engineering industrial hygiene food and nutrition child welfare education in public health public health nursing and epidemiology Further information can be obtained from the American Public Health Association 50 West 50th St New York

SMALL POX has become an extinct disease in Poland owing to the strict enforcement of the law on compulsory vaccination and re vaccination

THE October issue of the *British Journal of Dermatology and Syphilis* is a jubilee number (1888–1938) containing retrospective articles by Drs J M H Macleod James H Sequeira and Sir Ernest Graham Little with portraits of the editors of the journal and celebrated British dermatologists of the past fifty years

THE present issue of the *Nederlandsch Tijdschrift voor Geneeskunde* the organ of the Dutch Medical Association, is a Boerhaave number containing the addresses delivered at the Boerhaave celebrations at Leyden on September 23 (see NATURE September 17) of which the following are in English Boerhaave s influence upon American medicine by Prof Henry E Sigerist Boerhaave and the early medical school at Edinburgh by Dr J D Comrie the influence of Boerhaave s Institutiones medicae on modern physiology, by Prof J F Fulton, and Boerhaave as a botanist by Mr T A Sprague

WE regret to find that the name of S Abdul Aziz was inadvertently omitted from the letter entitled Raman Spectra of Compounds with Three Benzene Rings published in NATURE of September 10, p 477 The letter was a joint one from Prof S K Mukerji and S Abdul Aziz

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P 758

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Mechanism of Light Flicker Fusion during the Course of Dark and Light Adaptation

IT follows from the data of Schaternikoff, Fedorov and Fedorova[1], R Lithgoe and K Tansley[2], and others, that during dark adaptation the critical flicker frequency for photopic vision is decreased It has been shown by Alexanian and Livshitz in Orbeli's laboratory (Leningrad) that the same is the case in scotopic vision provided the effect produced by the change of threshold sensitivity during dark adaptation is eliminated Critical frequency was therefore always determined for a light intensity which was a multiple of the threshold at the given moment In the course of light adaptation the critical frequency is, on the contrary, increasing (R Lithgoe and K Tansley) The purpose of the present study was to analyse the causes underlying the above change of critical flicker frequency in the course of dark and light adaptation Both dark and light adaptation were therefore studied by means of a special optical device which afforded the possibility of watching in a homogeneously illuminated field (angular size about 10°) the flickering of a central point visible within an angle of 1°, the brightness of which was equal to that of the background

The critical frequency of flicker was found to undergo a decrease during dark adaptation and a considerable increase during light adaptation, the latter only up to a certain limit, whereupon the critical frequency has somewhat decreased (Fig 1, line "a") With red and green stimuli light adaptation proceeds similarly provided the initial flicker frequencies are similar (Fig 2) In the light of Adrian's data on the action current of the isolated optic nerve of the eel induced by stimulation of the retina with flickering light, Piper's data on isolated eyes of a number of animals (dog, ape, etc), Sachs's findings regarding the action currents of the human eye submitted to intermittent light, as well as the data of Granit and Hartline and Graham, who have studied the impulses in the isolated optic nerve fibres without synapses in the retina of *Limulus poliphemus* (cf also Barcroft[3]), the conclusion will seem irrefutable that fusion of light flicker takes place in the synapses layer of the retina As to the mechanism of this fusion, it may be suggested that it results from deformation (enlargement) of impulses set up by the action of light on the cones (and rods) of the retina during the passage of the impulses through these synapses, due to the resistance they offer to the passage of the impulses Light adaptation reduces the resistance of synapses, establishing stable connexion between them, while dark adaptation produces an opposite effect It becomes thus comprehensible why in the course of light adaptation intermittent light seems to become progressively more bright (the critical frequency is increased), while during dark adaptation an opposite impression is produced (Ives' concept[4] that diffusion of impulses occurs in the optic nerve fibres themselves is opposed by the recent data, according to which impulses are not deformed during their passage along the nerve fibres Nor can we agree with Houstoun[5] that light flicker fusion occurs "before the stimulation of the rods and cones")

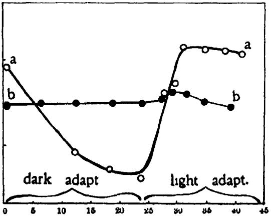


Fig 1.

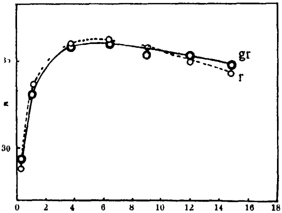

Fig 2

Our suggestion was completely confirmed by special experiments carried out in this laboratory on the effect of strychnine injections (1 c c. of 0 1 per cent solution) and of illumination of the other eye upon the critical flicker frequency.

Twenty-four hours after strychnine injection, neither light nor darkness could influence the fusion of light flickers, which can be accounted for only from the point of view presented above (Fig. 1, curve *b*)

The main effect of strychnine upon the visual apparatus consists, according to Granit[6] and others*, in the establishment of stable connexions within the synapses, thus reducing their resistance in facilitating a neural interconnexion between the ganglion cells of the retina This is also the reason why illumination of the other eye which induces centrifugal impulses in the optic nerve of the first eye is likewise ineffective Without strychnine, the curve *a–b–c–d* is obtained; and one day after the strychnine injection, the curve *e–f–g–h* (Fig 3) (Similar curves were obtained with a dark background)

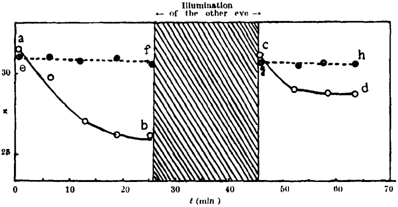

Fig 3

It should also be pointed out that caffeine, which renders the perception more acute (Kräpelin) and increases the excitability of the nerve elements of the cortex (Lindberg), while increasing the final threshold sensitivity of the eye, did not exert, in our experiments, any noticeable influence upon the critical flicker frequency

The complete analogy between the critical flicker frequency during the course of dark and light adaptation with the corresponding curves for electric excitability of the eye (phosphen phenomenon—A Bogoslovsky) renders it very probable that the electric excitability of the eye after strychnine injection will likewise not change either in light or in darkness

Strontium in Sea Water and its Effect on Calcium Determinations

The concentration of strontium in sea water from the English Channel has been estimated by Desgrez and Meunier[1] as 13·5 mgm per litre, and this value has been confirmed by Thomas and Thompson[2], who obtained for water of 19 per mille chlorinity from the Pacific coast of America a value of 13 mgm per litre, corresponding to a Ca/Sr ratio of 30

In all methods of estimating calcium in sea water, it is to be expected that this strontium will be precipitated along with the calcium as oxalate, and will give rise to a positive error Spectrographic examination of both filtrate and precipitate obtained by precipitating calcium as oxalate from sea water shows that this is in fact the case, no strontium can be detected in the filtrate, and the Ca/Sr ratio in the precipitate is indistinguishable from that in the original sea water The error thus introduced into calcium determinations, which, though small, is much larger than the maximum analytical error of the best modern methods carefully performed, seems, however, to have been ignored by all authors, except for a statement by Thompson and Robinson[3] that "the presence of strontium is indicated when careful attempts are made to compare gravimetric and volumetric procedures for calcium in sea water"

In view of the very careful work that has been done recently, at the University of Washington and elsewhere, to establish authoritative ratios for the principal constituents of sea water, taking chlorinity as unity, it seems a pity that this error should go uncorrected The difficulty is that the final determination of the calcium, after it has been precipitated as oxalate, may be performed in various ways, it may be estimated volumetrically as oxalate or oxide, or it may be weighed as oxalate, as carbonate, or as oxide, and the magnitude of the strontium error varies in accordance with the method employed This may be seen from the table below.

Method	Ratio from which error is to be calculated	Value of ratio in col 2 when Ca/Sr 30	Error due to strontium (reciprocals of figures in col 3)
—	Ca/Sr (by weight)	30	3·3 per cent
Volumetric estimation as oxalate or oxide	Ca/Sr (by atoms)	65	1·5
Weighing as oxalate	$\frac{CaC_2O_4 \, H_2O}{SrC_2O_4 \, H_2O}$	49	2·0 ,
Weighing as carbonate	$\frac{CaCO_3}{SrCO_3}$	45	2·2 ,
Weighing as oxide	CaO/SrO	35·5	2·8 ,,

Since no method exists of separating quantitatively small amounts of strontium from relatively large amounts of calcium, it is clearly impossible to obtain the true calcium content directly by analysis. It is desirable therefore that an arbitrary meaning should be given to the term "calcium content", as has already been done for chlorinity, so that its value shall bear a constant and known relation to the true calcium value, and shall at the same time be ascertainable by direct analysis Most determinations in the past have been performed by weighing the calcium as oxide , but recently volumetric methods, claiming considerable accuracy have been published[4] [5], and on the other hand it has been shown that calcium may be weighed conveniently and very accurately as carbonate[6]

On the whole, it seems best that a convention should be adopted in conformity with that already established for the halides, and it is hereby proposed therefore that, in speaking of the calcium content or calcium/chloride ratio of sea water, 'calcium' shall be taken to mean 'calcium after the strontium and barium have been replaced by calcium (The barium concentration is probably small enough to be completely negligible) This value will be given directly by volumetric methods , to methods involving weighing as oxide or carbonate, corrections of − 1 3 per cent and − 0 7 per cent respectively would have to be applied If this convention be adopted, the value of 0 02150 established by Thompson and Wright[7] for the Ca/Cl ratio becomes 0 02122

The decision must, of course, be left to those competent to speak with authority on the subject of chemical oceanography

Further discussion of certain analytical aspects of calcium determination in sea water and biological fluids of similar composition will appear shortly in a paper written in collaboration with Dr J D Robertson

Effects of Trimethylamine in Plants and Animals suggestive of Hormonal Influence

TRIMETHYLAMINE is known to accumulate in the sexual organs of many plants and animals[1] Its action as an aphrodisiac has also been observed Some connexion of trimethylamine with sex hormones appeared therefore possible On the other hand, the effects of animal sex hormones on flowering[2] and on the development of 'phytocarcinomata'[3] having been demonstrated, a further association of ideas concerning the possibility of similar parallelisms of action of trimethylamine did not seem to be too far fetched

I have accordingly tested the influence of trimethylamine on plants and animals by the following methods ·

(1) Trimethylamine in a 1 60,000 aqueous solution was introduced through a cut in the stem of young tomato plants by a method previously described[4] On the average, 17 c c of the substance was absorbed by each plant during the period May 12–July 18, 1936 The effect of this treatment was an increase of about 22 per cent in the number of flowers produced, as compared with the controls to which water was administered by the same method

(2) Another group of tomato plants was inoculated with a virulent strain of *B tumefaciens*, five inoculations being made on the main stem of each plant A 1 60,000 solution of trimethylamine was afterwards administered, using the above mentioned technique The control plants similarly inoculated were treated with water by the same method As a result of the treatment with trimethylamine, the total average weight of the tumours was about 17 per cent higher than that of the controls

(3) *Rhodeus amarus* males produce in the breeding season a characteristic colour change (*Hochzeitskleid*) and the females a marked elongation of the ovipositor These effects can also be obtained by the administration of sexual hormones[5] When *Rhodeus amarus* males were placed three to four months after the normal breeding season (July 1935 and August 1937) in an aquarium containing a 1 10,000 solution of trimethylamine, the brilliant carmine 'nuptial colour was obtained within 60–90 minutes No appreciable effect was observed on the females In the concentration used, the substance proved to be toxic to the animals

(4) In July 1935 (about three months after the mating season in Hungary), *Rana esculenta* males and females were placed in 1 25,000 to 1 6,125 solutions of trimethylamine In less than 24 hours, moulting was observed, and in another 24 hours the normally faint designs of the epidermis became as vigorously outlined as in the mating season From the third day on, the behaviour of the males showed an awakening of the sexual instinct, although no copulation was observed On the fourth day, the colour change attained its maximum and lasted until the seventh day, when owing to the toxicity of the substance the experiment was discontinued

(5) *Triton cristatus* males and females were placed about three months after the mating season in a 1 1,000,000 solution of trimethylamine The successive phases of colour change similar to those observed in the breeding season had begun about two hours after the beginning of the treatment, and were fully displayed in five hours They faded again at the end of 13 hours The effects of a second treatment lasted 24 hours, however, and those of a third treatment until the end of the experiment, namely, 23 days Signs of awakening of the sexual instinct were shown by the males from the sixth to the twentieth day of the experiment , but neither did their crests appreciably develop nor did copulation take place No additional effects were obtained by increasing the concentration of the solution to 1 25,000

The histological examination of some organs of the treated newts, kindly undertaken by Dr A Wolszky (Hungarian Biological Research Institute, Tihany), has shown the following results the histological structure of the skin is normal, but the amount of pigment normally diffused in it is greatly reduced The bulk of the pigment is condensed in big blocks of 120–150 μ diameter in the corium, thus differing markedly from the normal consistency and distribution In the ovary the number of ripening eggs (filled with eosinophile yolk granules) appears to be increased Their diameter reaches 1 2 mm In the oviduct no histological changes were observed

Although some of the above preliminary findings are suggestive of hormonal effects, further experiments are in hand to establish how far this claim is justified.

Colchicine and Acenaphthene as Polyploidizing Agents

From the communication by B. R. Nebel[1] in Nature of August 6 reporting that acenaphthene solution does not induce chromosome doubling in *Tradescantia*, I believe that he is not well acquainted with the method by which I worked. In my first paper[2] I described the method as follows: "Soaking seeds from *Triticum vulgare*, *Tr. monococcum*, and *Secale cereale* in saturated aqueous solution of acenaphthene, with excess of crystals (sublimated particles), during two days and then putting them into Petri dishes, watered with the same solution, we found that the seedlings react morphologically in the same way as they react to colchicine solution" (p. 198). In the treated material polyploid cells and sectors were found. Excess of crystals was necessary (which act in the form of sublimated particles), since saturated solution alone was not sufficient to induce chromosome doubling. (I shall not quote here the further elaborations of the method[3] described in my paper quoted by Nebel, since it was published in Nature.)

We know now quite well that the active principles[4,5,6] are the sublimated particles, since dry acenaphthene crystals act effectively from a distance in inducing chromosome doubling; therefore I am applying it now by covering the plants or the shoots with reagent tubes (glasses) or cylinders the walls of which are covered with acenaphthene crystals from inside. For some experiments we dissolved the crystals in ether, shook up the solution in the reagent tubes and cylinders, the ether evaporated rapidly and the walls of the tubes and cylinders were left covered with crystals.

Treating branches of *Nicotiana longiflora* with acenaphthene sublimating particles, I produced tetraploid and octaploid shoots from which seeds were produced and further polyploid plants were raised.

Applying colchicine solution I obtained tetraploid plants from *Nicotiana rustica*, *N. tabacum*, *N. glauca*, *N. suaveolens*, *N. megalosiphon*, *N. Velutina*, *N. alata-Sanderæ*, *N. suaveolens-alata*, *Petunia hybrida*, *P. parviflora*, etc., and octaploid in *N. alata-Sanderæ*. Treating *Lactuca* (salad) germinating seeds with colchicine solution, I obtained only polyploid cells, but no polyploid shoots or plants. Tetraploid *Lactuca* plants were obtained, however, by treating germinating seeds with acenaphthene sublimated particles from crystals.

In studying the procedure of the meiosis and mitosis in plants treated with acenaphthene and colchicine[4-7], and inducing polyploid cells, sectors and whole shoots and plants by these two agents in many species and hybrids, I have collected data on the basis of which I can affirm (contrary to Nebel) that acenaphthene interferes with the mitotic and meiotic processes in a way similar to that of colchicine, creating conditions for chromosome doubling. Thus acenaphthene can be successfully applied for inducing polyploidy, as had already been done in *Nicotiana*, *Triticum*, *Lactuca*, etc.

It should be mentioned here that the effect of the acenaphthene is increased with increase in the amount of sublimating particles and in the time of exposure. The quantum of the particles increases with increase of crystal surface and with increase of temperature (within limits). Large amounts of sublimated particles, and also a long time of exposure without interruptions, may injure and even kill plant tissues.

Production of Growth-Substance by Clover Nodule Bacteria

Thimann[1], using the standard *Avena* technique, showed that a growth-substance is produced in considerable amount in root nodules. He furthermore claimed that the growth-substance produced is not derived from the meristematic tip of the nodule, but comes directly from the bacterial tissue. He found that the symptoms induced by 3-indole-acetic acid upon roots closely resembled those produced, in Molliard's work, by the action of sterile filtrate of nodule bacteria upon pea roots, and he consequently believed that the bacteria cultivated in laboratory media produce growth-substance in considerable amount.

Using Went's pea test technique[2], I have confirmed Thimann's view that nodule bacteria do produce a good deal of growth-substance in a culture provided with a small amount of tryptophane in the medium. The filtrates of four weeks old cultures of strains of clover nodule bacteria grown in a yeast-water medium containing 0.02 per cent tryptophane were tested against pea shoots prepared according to Went's method. The results of a typical experiment are shown in the accompanying table.

	*p*H	Dilution				
		1/4	1/8	1/16	1/32	1/64
Uninoculated control	8.2	O	O		−	−
Strain 2057 in medium without tryptophane	8.4	O	O	O	O	O
Strain 2057	7.9	+	+	+	±	O
Strain 2027	8.0	+	+	+	±	O
Strain 202	7.8	+	+	+	O	O
Urine	−	+	+	±	−	−

+ Positive reaction O No reaction
± Reaction doubtful − Not tested

It appears that strains that are effective in fixing nitrogen in the plant produce in this tryptophane medium very little if any more growth-substance than do the non-beneficial strains that are not effective in fixing nitrogen The old laboratory strains which have lost their virulence, that is are unable to produce nodules when supplied to the plant, were found in most experiments to produce less growth substance, as illustrated by the strain 202 in the table

Cyclical Changes in the Adrenal Glands of Spayed Rats

In an earlier note published in these columns[1] it was reported that cyclical variations occur in the responsiveness of the uterus of spayed monkeys to constant œstrogenic stimulation In view of several considerations, it was suggested in a later communication[2] that variations in the size and function of the adrenal cortex such as occur in normal rats in the œstrous cycle[3], may be responsible for these cyclical variations in the uterine response Later work[4] showed that cyclical uterine changes occur in spayed rats as well as in monkeys, and that the adrenal gland is probably concerned in their occurrence[5]

We have now found that the adrenal gland does in fact continue to fluctuate in size in an approximately five day rhythm in spayed rats (Glaxo strain) that are injected daily with the same threshold dose of œstrone The gland is larger at œstrus than in the diœstrous period the observations being made on the basis of the difference between the ratios of adrenal weight in grams to body weight in kilograms The difference between the two means in an equally divided experimental group of 38 rats of similar age and weight was significant *P* being less than 0 01

Toxicity of Mercury Vapour to Insects

A reference was made in a communication under this title by H C Gough in Nature of May 21, p 922, to an old Indian custom of placing a small quantity of mercury in a container amongst stored pulses It seems worth while to direct attention to an analogous belief amongst the Āhoms A notable feature of the Āhom reign in Assam was the construction of large 'tanks' or open reservoirs of water, of which the surrounding embankment and the level of the water enclosed therein were considerably above the level of the surrounding countryside Most of these tanks are in existence to day, one fine specimen near Sibsagar town having a perimeter of more than two miles The tanks were dug on the site of a spring, the position of the spring within the tank being indicated by a substantial post, and it is said to have been the custom of the Āhoms to bury an earthenware vessel of mercury at the foot of the post and on the site of the spring in the belief that the water would thereby be purified and the tank remain clean and free from undesirable vegetable growths

We are not aware of any documental evidence for these statements, but they are so well founded in the folk lore of the people that there seems little reason for doubting at least a substantial basis of truth

Ninhydrine Reaction in the Quantitative Determination of Different Amino Acids

In the so called ninhydrine reaction there is formed in addition to carbon dioxide, an aldehyde corresponding to the particular amino acid present When the reaction is carried out so that the formation of aldehyde is as quantitative as possible, the amino acid can be determined by the aldehyde We have made this method quantitative for α alanine which gives acetaldehyde[1] The ninhydrine reaction can also be applied to the quantitative determination of certain other amino acids Thus one of us (Laine) has developed the method for the determination of leucine by means of isovaleraldehyde formed in the reaction[2] We are continuing our work for the determination of other amino acids in the same manner

The ninhydrine reaction for the determination of the total amino nitrogen has also been improved by us The reaction must be accomplished at *p*H 2–2 2 as the ammonium sulphate employed as the condensing substance forms colour with ninhydrine already at *p*H 2 5 and above that

Energy Levels of the ^{24}Mg Nucleus

Using the cloud chamber method, we[1] have investigated the beta ray spectra of ^{24}Na The K U plot showed clearly the existence of two groups The energy difference between the higher energy group and the lower one is about 1 Mv, their relative intensities being 2, 3 and 1 respectively The higher energy group lies on the first forbidden Sargent curve, for which $\Delta i = 1$, while the lower one is on the permitted Sargent curve, $\Delta i = 0$

Kurie and Richardson[2] and Richardson[3] have investigated the gamma-rays emitted by ^{24}Na, their results being as follows

Energy (Mv)	1 01	2 04	3 00 ± 0 05
Relative intensity	1 05	0 95	0 65 ± 20 per cent

We have tried to construct an energy level scheme of ^{24}Mg which accounts for all the above experimental facts regarding the beta- and gamma rays For this purpose we made, besides the energy relations, some plausible assumptions as follows

(1) In the first place, ^{24}Na is assumed to be in a single energy state because it has only one decay constant, and this nucleus emits two beta ray groups

resulting in two excited states of ^{24}Mg These go over either to the ground state or to lower excited states with the emission of gamma rays

(2) The change in angular momentum due to the beta ray emission is $\Delta i = 1$ for the transition corresponding to the higher energy group, $\Delta i = 0$ for the lower one and $\Delta i \geq 3$ for any other transitions

(3) Moreover, the ground state of ^{24}Mg has zero spin since the nucleus contains $4n$ particles

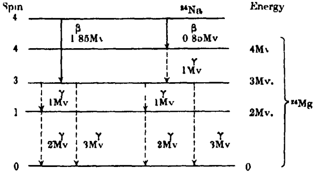
Now, according to Bethe[4], the probability of emission of multipole radiation of order Δi is given by the following formula

$$\frac{1}{\tau} = \frac{1}{5 \times 10^{21} (\Delta i\,!)^2 (20/\hbar\omega)^{2\Delta i + 1}} \text{ sec}^{-1},$$

where $\hbar\omega$ is the energy of gamma rays in Mv and Δi is the change in angular momentum during the process of emission

Taking the intensity ratio of the two beta rays groups into account, we can calculate the relative intensities of the gamma rays by means of this formula, and compare them with the observed values of Kurie and Richardson

Of the level schemes which have been studied for the cases having two and three excited states, only the one shown in the accompanying diagram satisfies the observed intensity relations of the gamma rays



Level Scheme of ^{24}Mg

The relative intensities of the gamma-rays calculated for this level scheme are as follows

1 Mv	2 Mv	3 Mv
1 26	0 86	0 52

These figures agree with Kurie and Richardson's values within their limit of experimental error of 20 per cent All the other level schemes give intensity ratios that deviate greatly from the observed values

It is probable that there exists some uncertainty in the determination of the intensity ratio of the two beta ray groups, and the above value (2 3) may be under estimated This, however, does not materially affect the above conclusion

I wish to express my gratitude to Dr Y Nishina for his kind guidance throughout the course of this work

CN Bands in the Night Sky Spectrum

In August 1933, at the Pic du Midi, we photographed the spectrum of the night sky simultaneously at the horizon and at the zenith On each of the four spectrograms so obtained, we noticed that the Vegard Kaplan bands of molecular nitrogen weaken at the zenith and that new radiations can be distinctly seen in their place For example, the ($3 \rightarrow 15$) λ 4531 Vegard Kaplan band, strong and broad at the horizon, disappears almost completely at the zenith, while, at λλ 4554 and 4576, we observed radiations the intensity of which remained constant So we were led to draw up a list including about thirty radiations the intensity of which does not vary obviously from the zenith to the horizon

The probable presence of the CH bands in the sky spectrum and the analogy of the latter with cometary spectra led us to search in the preceding list for other band systems associated with carbon Let us examine the CN case The 4554 and 4576 sky radiations can be identified with the R and P branches of the $1 \rightarrow 3$ band in the CN violet spectrum But in order to justify this identification we must find in the list the other CN bands Indeed we observe the bands of the same sequence R ($5 \rightarrow 7$) near λ 4480, R and P ($4 \rightarrow 6$) near λ 4499, R and P ($3 \rightarrow 5$) near λ 4517, we notice also the R ($3 \rightarrow 4$), R ($2 \rightarrow 3$) and P ($3 \rightarrow 4$), R and P ($1 \rightarrow 2$), R and P ($0 \rightarrow 1$) bands

In order to go further, we must give up this list, obtained from only four spectrograms and consequently a little brief, and use the tables of wavelengths which result from all the observations we have made since 1933 Kaplan has already found a good concordance between the wave lengths given by Gauzit and those of the 'tail' bands[1]

But before considering the bands with high vibrational quantum numbers, it is certainly useful to consider the beginning of the sequences For the $v' - v'' = -1$ and -2 sequences, we find in the sky (1) radiations near the origin of the P and R branches, (2) radiations corresponding to rotational quantum numbers near $K = 10$ This distribution is not surprising In the laboratory, we observe it in presence of active nitrogen, the same distribution was found by Dufay in the comets[2] In this last case, the maxima correspond precisely to $K = 9$ or 10 when the distance from the sun is one astronomical unit

It is difficult to go on with a similar attempt at identification for the $v' - v'' = 0$ and $+1$ sequences, for the P and Q branches of the successive bands overlap more and more Further, we come to a region where the night sky spectrum is imperfectly known

As to the 'tail' bands it is interesting to notice that the coincidences observed by Kaplan concern the origin of the bands, although he did not express this precisely After examination of the structure, we observed also good coincidences with the lines the rotational quantum numbers of which are near 10 These lines are usually the most intense in the laboratory

Finally, it seems that the bands of the violet cyanogen system are found among the night sky radiations the intensity of which does not increase obviously from the zenith to the horizon But among the thirty radiations of the list mentioned at the beginning of this communication, there still remain twenty to identify

Absorption Spectrum of Cobaltous Chloride in Deuterium Oxide

SMALL differences in the colour of solutions of copper sulphate and silver permanganate when dissolved in deuterium oxide instead of ordinary water have been reported by Bell[1], and Hein and Bähr[2] respectively Displacement of the absorption lines in the spectrum of potassium chrome selenium alum $(KCr(SeO)_4 12\,H_2O)$[3] and of several complex chromium salts[4] when H_2O is replaced by D_2O have also been observed Bell s work was confirmed by Brodsky and Zanko[5], who made spectrophotometric measurements with copper sulphate in pure H_2O 43 6 per cent and 92 7 per cent D_2O mixtures

I have determined the absorption curves of anhydrous cobaltous chloride dissolved in H_2O and 99 6 per cent D_2O These curves lie within the visible region between the wave lengths of 4000 A and 6000 A and they were obtained by means of a wave length spectrophotometer Distinct differences were apparent, the molecular extinction coefficient in D_2O being smaller throughout the region of absorption, and the height of the maximum is lower The accompanying table indicates the nature of those differences at various points of the curves Up to 4900 A, the difference is practically insignificant, above 4900 A it increases and appears to be greatest between 5300 A and 5400 A that is at lower frequencies than the maximum

Wave length (A)	4700	4800	4900	5000	140	5300	5400	5600
Mol extinct coef								
Solvent D_2O	2 82	3 17	3 46	3 92	4 14	3 30	2 54	1 04
Solvent H_2O	2 89	3 19	3 48	4 02	4 34	3 67	2 84	1 20

These differences are comparable to those obtained by Brodsky and Zanko for copper sulphate

Photo-electric Absorption of Radiation in Gases

A LETTER on the above subject by Page[1] and a reply by Menzel[2] have recently appeared in NATURE While I am in agreement with most of Dr Menzel s letter, I feel that discrepancies between theory and laboratory experiment in the above field are more radical than his remarks would appear to suggest

Theoretical calculations are based on the assumption that interactions between neighbouring atoms or molecules may be neglected, so that the atomic absorption coefficient is a true constant, independent of temperature and pressure Detailed experiments[3] have shown that this assumption is true only at low pressures The transition probabilities for the photo electric process for cæsium, for example, are greatly reduced by the presence of only a few millimetres of the rare gases Much larger effects are produced by active gases like hydrogen or by the interaction of cæsium with cæsium It should be emphasized that the continuous state is much more sensitive to these pressure effects than the internal quantized states of the atom These results indicate that it is not correct to base astrophysical calculations on the assumption that the absorption is proportional to the number of atoms present, except at low pressures Thus atomic absorption coefficients measured in the laboratory or deduced from one set of stellar data cannot, in general, be used to make calculations on a mass of gas at another temperature and pressure

Even if we confine ourselves to the region of low pressures, the agreement between theory and experiment is by no means satisfactory It has been shown that for hydrogen[4] and the alkali metals[5] the absorption should theoretically decrease monotonically from the series limit in the direction of short wave lengths This conclusion is independent of any precise assumption concerning the form of the atomic field[4] Experiments are available for potassium[6], rubidium[7] and cæsium[8] For potassium and cæsium the absorption is found to reach a minimum a short distance from the series limit and then to increase again in the direction of short wave lengths (For rubidium it is probable that the minimum is just at the end of the observed region of the spectrum)

A second prediction is that there is no discontinuity in the absorption at the series limit This result has been rigorously calculated for hydrogen[9] and probably applies also to the alkali metals In a recent paper[10] I have assembled strong experimental evidence which shows that the absorption changes sharply, by a factor of about two, at the series limit This discontinuity is found for hydrogen and for all the alkali metals but for hydrogen its magnitude is probably small

These discrepancies suggest that the present calculations omit some essential factor or else that the normalization of the continuous states is not correctly treated I believe, with Dr Menzel, that the wave mechanics will eventually yield a satisfactory theory for this problem I think, however, that attempts to apply Kramers formula (or the wave mechanical modifications of it) to astrophysical problems may be very misleading and certainly must be so at high pressures At present, it would appear to be necessary to admit that we have no theory of continuous absorption which is satisfactory in the sense of being well verified by terrestrial experiments While Kramers formula may be useful as a rough guide, it is safer to regard the opacity as a quantity which cannot be determined theoretically, and, in comparing one system with another, to remember that the atomic absorption coefficient is, in general, a function of the temperature, pressure and state of ionization of the gas surrounding the absorbing atom

Technique of the Painting Process in the Kailasanatha and Vaikunthaperumal Temples at Kanchipuram

THE Kailasanatha and Vaikunthaperumal temples are situated in Kanchipuram a town forty five miles west south west of Madras by rail The former was built during the time of the Pallava king Narasimhavarman II *alias* Rajasimha (A D 680–722)[1] and the latter by Nandivarman II *alias* Pallavamalla (A D 725 790)[1]

The paintings in these two temples are some of the best specimens of Hindu mural art of the classical or Ajanta school Those in the Kailasanatha temple are executed on the inner walls of the cells lining the outer walls of the courtyard But most of them have either disappeared or faded, due to the vicissitudes of time and environment These paintings probably belong to the seventh–eighth centuries A D and were brought to light in 1931 by the French archaeologist, Prof Jouveau Dubreuil of Pondicherry

The paintings in the Vaikunthaperumal temple, which probably date from the eighth–ninth centuries A D , are under the eaves and in the niches (*kudus*) of the central tower or the *vimana* Most of them have disappeared, leaving only a miniature head But traces of paint are to be seen everywhere on the *vimana* The paintings in these two temples are older than those in the Brihadisvara temple at Tanjore[2] or in the temple of Vijayalaya Cholesvaram at Narthamalai in the Pudukottah State[3]

As an extension of my studies on Pallava paintings[4] in India, I recently investigated the methods and materials of Pallava artists in these two temples

The paintings in these two temples are executed on surfaces of sandstone The painted stucco consists of the *rinzaffo* or the rough coat of lime plaster with fine lime wash thereon the latter being applied while the former was still wet On the lime wash is a layer of paint film In the case of some of the paintings in the Kailasanatha temple, there is no rough plaster, and the paintings are executed on the lime wash directly applied to the sandstone The thickness of the rough plaster varies with the inequalities of the surface of the sandstone

The thicknesses of the different layers composing the stucco are

	Kailasanatha temple	Vaikunthaperumal temple
Painted stucco	2 1 4 3 mm	3 4 4 7 mm
Lime wash	0 3 mm	0 3 mm
Paint film	0 3 mm	0 8 mm

The results of analyses of the rough plasters are as follows

	Kailasanatha temple (per cent)	Vaikunthaperumal temple (per cent)
Moisture	1 08	0 17
Carbon dioxide	9 45	21 52
Loss on ignition (excluding moisture and carbon dioxide)	5 66	2 66
Silica (SiO_2)	65 37	46 63
Iron and alumina ($Fe_2O_3 + Al_2O_3$)	2 06	1 97
Lime (CaO)	15 71	26 73
Sulphuric anhydride (SO_3)	nil	0 15
Magnesia (MgO)	nil	0 04
Undetermined (mostly alkalis)	0 67	0 13
	100 00	100 00

The rough plasters in both the temples have been laid in true fresco technique, and they contain only sand as inert material

The pigments used in these two temples are the same Carbon has been used for black, yellow and red ochres for yellow and red and terre verte for green The pigments have been applied in lime medium or in fresco secco technique

Full details of the investigation will be published elsewhere

The Tetrads in Apoda (Amphibia)

WORKERS on urodelan spermatogenesis have reported the occurrence of large multiple rings in the first maturation divisions of the animals of that group These multiple rings form the most conspicuous of the tetrads in practically every urodele studied Multiple ring tetrads in Anura are very rare and are practically confined to some members of the Discoglossidae (*Alytes obstetricans* Janssens and Willems[1] *Bombina pachypus* Galgano[2] *Bombina orientalis* Sato[3]) Swingle[4] reported such multiple ring tetrads in the male sexual cycle of the tadpoles of *Rana catesbiana* of 40 60 mm length while in the second larval sexual cycle of this animal the typical anuran kind of tetrads (simple rings) were present Swingle and later Iriki[5] advanced the view that the multiple ring tetrad must be regarded as the ancestral type of tetrad in Amphibia and this view has been further emphasized recently by Sato[3], who has found such compound tetrads in *Bombina orientalis*

The position of Apoda is very interesting in this respect It has already been reported[6,7] that in *Ichthyophis glutinosus* the larger chromosomes form multiple ring tetrads In this animal the two large V shaped and one large rod shaped pair of chromosomes form during meiosis three compound tetrads I have recently examined *Uraeotyphlus menoni* another example of Apoda from South India and in this form I have found that there are three pairs of large V shaped chromosomes which form compound tetrads Whether the view that the multiple ring tetrad is the ancestral type in Amphibia be accepted or not the resemblance between Urodela and Apoda in this respect is very striking A full description of the spermatogenesis in *Uraeotyphlus menoni* will be published separately

Prof Buckland and Oxford

IT may be of interest to note that the verses on Buckland quoted by Prof J L Myres (NATURE Oct 8 p 673) were actually published at Oxford in 1869 in an entertaining little volume entitled Fugitive Poems connected with Natural History and Physical Science collected by C G B Daubeny F R S sometime professor of chemistry and botany in the University of Oxford They are there dated Dec 1, 1820 and attributed to Richard Whately at that time fellow of Oriel and later Archbishop of Dublin The verses are reprinted in the Life and Correspondence of William Buckland published in 1894 where it is stated that Buckland was so pleased with them that he had copies lithographed to present to his friends

V A EYLES

27 Mentone Terrace
Edinburgh 9

THE verses on Buckland appearing in NATURE of October 8 p 673 were published in The Life and Correspondence of William Buckland, by his daughter Mrs Gordon (London 1894) page 41 It is there stated that they were written by Richard Whately afterwards Archbishop of Dublin and that Buckland had them lithographed and gave copies to his friends The version there printed contains minor variations from that given in NATURE and is entitled Elegy Intended for Professor Buckland. December 1st 1820 In the same volume there are several other sets of amusing verses on geological subjects

The verses are also printed in Frank Buckland s Curiosities of Natural History Second Series (1903 edit pp 144–146)

Points from Foregoing Letters

FROM a study of the action of strychnine and caffeine upon the critical flicker frequency Prof N T Fedorov and Lucy Mkrticheva conclude that fusion of light flickers in the synapses of the retina during dark and light adaptation results from the resistance offered by these synapses to the passage of impulses set up in the cones and rods of the retina so that the impulses undergo deformation and enlargement

Spectrographic analyses by D A Webb show that the presence of strontium gives rise to errors in the estimation of the calcium content of sea water Since the magnitude of the error varies with the method employed it is suggested that a conventional interpretation should be given to the term calcium content as is given to the term chlorinity, calcium shall be taken to mean calcium after the strontium and barium have been replaced by calcium'

Dr L Havas reports that treatment with dilute solutions of trimethylamine increased the flowers produced by tomato plants and the average weight of tumours produced by *B tumefaciens* Also it had effects suggesting sex hormonal influence upon *Rhodeus Rana* and *Triton*

Prof D Kostoff considers that B R Nebel s failure to obtain chromosome doubling by treatment of *Tradescantia* with acenaphthene solution was due to the method employed The active agent is, he states the sublimated particles and he has found acenaphthene crystals to be effective at a distance in producing chromosome doubling in *Nicotiana Triticum* and *Lactuca*

A table showing the growth stimulating effect upon oat seedlings of filtrates of various strains of clover nodule bacteria (in presence of tryptophane) is given by H K Chen The non beneficial strains (which do not lead to nitrogen fixation) appear to be equally effective as growth stimulants

The adrenal glands in spayed rats injected with œstrone fluctuate in size in an approximately five day rhythm, according to Dr S Zuckerman, Dr G Bourne and D Lewes

It is stated by W Wight and P K Barua that an account in the folk lore of Assam indicates that the Ahom tribes used to bury an earthenware vessel of mercury on the site of springs which were feeding reservoirs in the belief that the water would thereby be purified

An energy level scheme for the nucleus of nitrogen atoms of mass twenty four is outlined by A Sugimoto to account for the energy and intensity of the beta and gamma radiations emitted by sodium atoms of mass twenty four from which the magnesium atoms are derived

A number of cyanogen bands are identified by Prof J Cabannes Prof J Dufay and J Gauzit among radiations recorded in the spectrum of the night sky These radiations do not change in intensity from the zenith to the horizon and consequently it may be presumed that they have their origin outside the earth s atmosphere

The molecular extinction coefficient of cobaltous chloride dissolved in deuterium oxide (heavy water) is found by D C Martin to be smaller than in water throughout the region of absorption

In connexion with the use of Kramers absorption formula in astrophysical calculations Prof R W Ditchburn points out that the atomic absorption coefficient is in general a function of the temperature, pressure and state of ionization of the gas surrounding the absorbing atom

S Paramasivan reports that the Pallava paintings (seventh ninth centuries A D) in the Kailasanatha and Vaikunthaperumal temples at Kanchipuram (South India) have been executed in fresco secco technique He gives the results of analysis of the plasters and the pigments Carbon (for black), yellow and red ochres and terre verte (for green) have been used as pigments

B R Seshachar finds that in the South Indian amphibian *Uraeotyphlus menoni* there are three pairs of large V shaped chromosomes which form compound tetrads, similar to the large multiple rings observed by other workers in Urodela

Research Items

Arteries of Peking Man

PROF. FRANZ WEIDENREICH has made a study of the evidence afforded by endrocranial casts of fossil hominids for the character of the meningeal artery, with special reference to its bearing on the phylogenetic problem (*Palæontologia Sinica*, No. 110, N.S.D. No. 3, 1938). It is known that the medial meningeal artery exhibits a rather great variability in recent man with respect to its ramifications. Two main groups are distinguished, of which the second, in which the trunk is divided at a low level into two branches, is the more primitive. In *Sinanthropus* the trunk is as a rule divided into two, or even three branches. There are numerous variations in detail, but the ramifications of all branches, which are rather abundant in recent man, are markedly poor. Little is known of the conditions of the medial meningeal artery in anthropoids or lower apes; but when the gibbon and the great apes are compared with *Sinanthropus* and recent man, it becomes evident that they bear a much closer resemblance to *Sinanthropus* than to recent man. The endocasts of Neanderthal man reveal that *Sinanthropus* is more primitive. Rhodesian man exhibits an instructive example of a mixture of primitive features and a far advanced character; while the peculiarities of the Neanderthal type, so far as known, confirm the conception that it is an intermediate form between *Sinanthropus* and recent man, as supported by the characters of teeth, brain and skeleton. The arterial pattern, in fact, comes close to the more primitive type of recent man. *Pithecanthropus* exhibits a typical hominid pattern similar to advanced *Sinanthropus*, but shows that the classification of *Pithecanthropus* as a gibbon by Dubois is untenable. The pattern of the Piltdown skull conforms in all respects to that of the more advanced type of recent man, while Swanscombe is also typical of recent man. It is evident that the ramifications of the artery in recent man are independent of both size of brain and racial character, but are peculiar to mankind at large.

Boat Processions in Egypt

AMONG the customs of Ancient Egypt which have survived in attenuated form into modern times is that of the boat procession from Karnak to Luxor, in which the god Amun, accompanied by his divine companions Mut and Khons, journeyed up the Nile attended by the Pharaoh and his court. In the opinion of most Egyptologists, this great festival of Opet, of which there is a representation on the walls of the temple of Ramses III at Karnak, survives in shadowy form in the boat processions of Luxor and Qena, held annually on the birthday festival of the Muhammedan patron saint of the towns. The festival and the course of the procession have often been described; but Mr. James Hornell points out in *Man* of September 1938, that the boats which form part of the procession have not received special attention. The procession at Luxor takes place on the fourteenth day of the month Sha'bân, when the participants gather around the gaily flagged boats in a square adjacent to the mosque of Sheykh el Miqashqash. The two boats are mounted on four-wheeled lorries drawn by men and boys. Each boat is freshly painted and fitted with a mast, on which is hoisted a blue striped lateen sail. Flags inscribed with texts are carried before and after the boats and float from the masts. In build these boats differ completely from the clumsily fashioned craft seen on the Nile. Their lines have a certain dainty elegance. They have clipper bows, long beak-like prows, and an open gallery frame built out beyond the transom stern. Instinctively we feel that in former years, when the festival had more importance than to-day, the boats used were really small replicas of Turkish galleys of the Middle Ages. The nearest related design to these Luxor craft is that typical of the galley-shaped sardine fishing boats now belonging to Malaga, a town held by the Moors until 1487.

Nutritive Value of Pasteurized Milk

Two sets of very similar, though not identical, experiments on the value of pasteurized, as compared with raw, milk for the nutrition of calves have been carried out at the National Institute for Research in Dairying (University of Reading) and the Rowett Research Institute, Bucksburn, Aberdeen, respectively, and the results are published in a joint report (Milk and Nutrition. New Experiments reported to the Milk Nutrition Committee. Part 3. The Effect of Commercial Pasteurization on the Nutritive Value of Milk as Determined by Experiments on Calves. Pp. 27. Shinfield, Reading: National Institute for Research in Dairying, 1938. *2s.*) In both experiments calves were divided into two similar groups, one group being fed on commercial raw, and the other group on commercially pasteurized milk from the same bulk, with equal small supplements of other foods in the later stages of the experiment. In brief, it may be stated that there was very little difference at the end of the experiment in the weight, growth and general nutrition of the two groups.

Under-water Movements of the Dipper

MANY observers have witnessed the fact that the dipper or water ousel (*Cinclus cinclus*) can remain and move freely under water, but there has been much speculation as to how a bird, having a specific gravity less than that of water, can remain upon the bottom. It has been suggested that it grips with its toes, but it has been seen walking upon the sandy bed of a stream which afforded no possibility of holding. Dr. J. M. Dewar suggests that in moving water the bird makes its way against the current, at the same time depressing its head and neck, so that part of the force of the current has the effect of pressing it downwards (*British Birds*, **32**, 103, 1938). In still water, the movement of the bird itself creates a current which has a similar effect. By a simple experiment with a block of wood, Dr. Dewar found that the speed of movement (by traction at a suitable angle) necessary to keep the block at the bottom of still water 10 inches deep was equivalent to a rate of only 0·5 mile per hour. More observations are required of the positions actually assumed by the dipper in its submerged movements under different conditions.

Cattle Bot flies in Norway

IN Norway, as in most European countries, the damage caused to cattle and hides by the presence of bot flies, *Hypoderma bovis* and *H lineatum* was excessive up to about 1920 L Reinhardt Natvig summarizes the position by stating that in 1922 the loss *in England was £15 million, and for England* (that is Great Britain) and its colonies £30 million Similar heavy losses are given for other countries In many countries however, the last twenty years has seen the institution of a vigorous campaign against these insect parasites which aided by the discovery of the value of derris in destroying the bots, has had strikingly successful results Natvig illustrates the effect of the measures taken in Norway by means of two maps the first showing the distribution and incidence of bots in cattle in South Norway in the years from about 1875 to 1920, and the second showing the same features in 1936 (*Naturen*, **62** 243, 1938) No evidence could be more convincing of the value of suitable preventive measures firmly and generally applied

Framework Grafting

AN interesting paper upon the regeneration of fruit trees by W F Walker, of Tasmania has recently been published (*J Roy Hort Soc*, **63**, Pt 9, Sept 1938) Many fruit trees in Tasmania ten years ago were not of the varieties most suited to modern needs The orchards could, of course, be destroyed and re planted, but several unproductive years would have to be spent The usual methods of re grafting and budding were also tried, but most success was obtained with framework' grafting The tree is headed back slightly, but only sufficient to retain the main framework of the branches Scions are then inserted at intervals of about 8 in all over the tree They can be disposed so that they occupy space to the best advantage, whilst future pruning and yield are also under control Closer spacing results in more fruit spurs, whereas more extended distribution gives greater vegetative growth Several methods for the quick performance of the grafting operation are described in detail, and the method offers the fascinating possibility of changing the variety without the loss of more than one season s crop Agricultural success is surely based upon such scientific versatility

Copper Deficiency in Cultivated Soils

RECLAMATION disease has been known in parts of Northern Europe for some time It was first recognized as a disease and named by Elema, the name being derived from its frequent occurrence on sandy heaths and moorland soil recently reclaimed These soils are rich in humus and strongly acid, but it is also found in peaty clay soils, in Denmark it has occurred in *Calluna* heath soils when brought into cultivation In Holland the reclamation by draining of large areas of waste sandy heath and moorland has met with difficulties from this cause, earlier investigations showed that heavy dressings of urban refuse gave some measure of control, such refuse contains copper salts, and later work has shown that copper sulphate alone was most effective Liming such soils increased the trouble, presumably lowering the availability of the copper and apparently also removing the small amount of available manganese Now the observations of C S Piper and of D S Riceman and C M Donald have shown that the 'coastal sickness' attacking grazing sheep in certain coastal areas of South Australia, and the poor crops of cereal obtained from the same soils, similarly yield to treatment with copper salts Dressings of 28 lb of copper sulphate to the acre gave much improved yields of wheat, oats and barley, and a new feature is the fact that the original soil in these cases has a very high content of calcium carbonate and a *p*H between 8 5 and 9 0 The same dressing of copper did not effect much improvement on pastures on these soils, but there is evidence that higher dressings of copper or possibly treatments including other elements such as iron, will greatly improve the pasturage The experimental work with the South Australian soils *is described in* Pamphlet No 78 of the Council for Scientific and Industrial Research, Melbourne

World's Natural Resources

IN a paper on this subject by Mr F E Lathe read at the June meeting of the American Association for the Advancement of Science in a series of communications on Science and Society, an attempt is made to reach a quantitative estimate of the world s resources in food power and minerals The conclusions are that with the continued applications of science, food supplies will suffice for a population of four times the present numbers, and that in power and most of the minerals of value to man there is little cause for anxiety This is true however, only when the world is considered as a single economic unit For the large number of units, most of which are striving for economic self sufficiency, the outlook is very different In order to illustrate the extreme mutual dependence of nations, Mr Lathe has compiled a table showing the extent of national sufficiency of the seven great powers of the world in coal, iron, copper, lead, zinc, nickel, tin, asbestos and petroleum Ascending numerical order shows decreasing sufficiency for national needs in each commodity The table shows that only the British Empire, the United States and the U S S R are each self sufficient in half or more than half these substances, but that no other power reaches that level in more than one commodity and several in no commodity Thus he illustrates his theme that international trade is essential and self sufficiency an economic fallacy

Antarctica and the Glacial Ages

THE Antarctic ice sheet in Pleistocene times, which has recently been under discussion in the correspondence columns of NATURE (see Sept 3, p 438), enters into the argument of a consideration by Prof F E Zeuner of the chronology of Pleistocene sea-levels (*Ann and Mag Nat Hist*, Ser 11, **1**, 1938), though the evidence taken into account concerns volume rather than extent Prof Zeuner compares actual conditions of sea levels observed in the Mediterranean in the work of A C Blanc with those postulated on the basis of the 'glacial control theory and the curves of solar radiation as calculated by M Milankovitch in 1930, which have been found to reproduce correctly and in detail the fluctuations in the extension of the ice during the Pleistocene age As a result of his comparison, Prof Zeuner finds that the observable climatic phases and changes of sea level in the Mediterranean agree completely with the fluctuations postulated on the basis of the curve of radiation In the course of his computation, he has occasion to observe that the Pleistocene sea levels appear to be related to the glacial phases of the northern hemisphere only. This conclusion is based on his view that at no time did the increase in the volume of ice in the Antarctic, as compared with present conditions, ever exceed one third of the present volume. Taking W. B. Wright's figures of approximately twelve million cubic kilometres as the present volume this would give in the most intense phase, that is, according to Milankovitch's figures of the solar radiation curve, the first phase of the last glaciation, Wurm I, an approximate maximum volume of 16 million cubic kilometres, whereas R. A. Daly's calculation for the Scandinavian ice cap of the last glaciation is approximately five million cubic kilometres, the variation in the antarctic sheet being put at four to six million cubic kilometres at most, as against a deglaciation of the north American, European and Siberian ice caps of 35 million cubic kilometres since the maximum.

Nickel Carbonyl

In 1931 Pauling (*J. Amer. Chem. Soc.*, 53, 1367; 1931) showed that, on the theory of directed valency, nickel carbonyl ($Ni(CO)_4$) should have a tetrahedral structure. In 1934, the Raman spectrum appeared to indicate a square configuration. In the following year, electron diffraction studies pointed to the tetrahedral structure, but the observed nickel-carbon distances suggested that resonance occurred with some structure (probably the square configuration) having nickel-carbon double bonds. Recently Bailey and Gordon (*J. Chem. Phys.*, 6, 225; 1938) and Crawford and Cross (*ibid.*, 6, 525; 1938) have measured its infra-red spectrum and their results are in satisfactory agreement. In the later paper the data obtained for liquid $Ni(CO)_4$ from 1μ to 8μ and for $Ni(CO)_4$ vapour from 1μ to 23μ, are analysed in conjunction with Raman spectral data, and indicate that the molecule has a tetrahedral structure, although the square configuration is not completely excluded. By the methods of group theory, normal co-ordinates, selection rules, and spectroscopic characteristics of both models have been derived, and the calculated values of fundamental frequencies, first overtones, and binary combination tones are compared with the observed results. Further, evaluation of the force constants shows that that for carbon-oxygen stretching has a value intermediate between those for $C = O$ and $C \equiv O$ bonds. Interatomic distances derived from force constants, agree with recorded values.

Lighting in Mines

The Mines Department has been co-operating with the manufacturers of safety lamps and lamp bulbs and with other associations with the object of assisting the industry. The Secretary for Mines has published a circular (M.D. No. 115) giving an account of the directions in which progress is being made. A most important development is in connexion with lamp bulbs. It is found that the argon now commonly used for lamp bulbs can be replaced advantageously by krypton. Recent investigations show that a higher lighting efficiency is obtained without any reduction in the life of the bulb or any increase in its current consumption. The tests made at the Mines Department Testing Station on krypton filled bulbs show increases of 20–30 per cent in lighting efficiency as compared with argon-filled bulbs of the same rating and life. The arrangements already in use for testing the performance of 'approved' bulbs will be applied to krypton filled bulbs, and collieries can therefore rely on the maintenance of the improved results obtained in the tests. The use of these bulbs, which are slightly smaller in diameter than ordinary bulbs, does not entail any alteration in the construction of the lamps or batteries, but as krypton is more expensive the bulbs are 2½*d.* dearer. The Secretary of Mines considers that owing to the high efficiency of the lamps the cost will be less for a given illumination. When the British Standards Institution undertook to specify the requirements for miners' lamp bulbs it was necessary to fix the life of the lamp. This was fixed at 600 hours, but it was found in practice that the actual working life was longer than this. The B.S.I. has now reduced the laboratory test of 600 hours to 500 hours as this greatly improves the efficiency. Attention is also directed to a new type of mercury vapour bulb for lamps fixed in position which works at the low pressure of 100 volts and gives high efficiency and a long life.

Measurement of Powdered Materials

The methods at present available for measuring the fineness of powdered materials used in engineering and industrial processes are described in detail in a paper submitted to the Institution of Mechanical Engineers by Dr. Harold Heywood, senior research officer of the British Coal Utilization Research Association. In it, definitions of particle size and shape are discussed and examples are given by means of typical size distribution curves for granular and powdered materials such as moulding loam, pulverized coal, Portland cement, and mine atmospheric dusts. For the size grading of comparatively coarse powders the method of sieving or screening is used, and the author explains and elucidates the theory of sieving and the relationship between particle size and sieve aperture. Differences in materials due to density, particle shape, stickiness, hygroscopicity, etc., have made it impossible to devise a general sieving specification and, as the process cannot in general be carried to completion, the usual practice is to specify an end point either by limiting the time of sieving or by continuing the operation until the weight passing the sieve in a given time is a stated percentage of the original sample or of the residue on the sieve. The first is an easy test to apply and, in the case of a particular material not likely to vary much in fineness, provides a useful test. The last is more sound fundamentally but is difficult to apply. In the grading of particles of sub-sieve size the processes used involve motion in a fluid. Dr. Heywood discusses the motion of such particles and gives a method by which their falling velocity can be calculated when the fluid flow around them is turbulent. He describes several processes which are employed in this form of analysis and explains their respective merits and advantages, including in his survey elutriation by means of air or water, sedimentation, hydrometry and the obscuring of a beam of light by dilute suspensions. Reference is also made to a device developed at the Fuel Research Station for comparing the fineness of viscous suspensions such as coal-oil mixtures for boiler firing, and consisting of a test tube containing the mixture and pivoted slightly above its centre of gravity. This is made to oscillate, and the changing time of oscillation as the powder sinks provides the means of determining the rate of settling.

Seventh International Management Congress

THE Seventh International Management Congress was held in Washington, D.C., in September last. According to a leaflet, issued to prospective members, a feature of the Congress was to be "the presentation of both American and foreign points of view on the most important aspects of management in relation to social and economic problems".

More than twenty countries sent delegates to the conference, the most notable exception being Soviet Russia, the absence of delegates from which may be regretted since a socialist State has many interesting management problems of its own. Business men were in a majority among the delegates, although there were also many research workers and university representatives, largely from the United States. This is in itself an interesting indication of the rapid development of the social sciences in the United States and their contact with the world of production and distribution and management in general.

More than two hundred papers were presented to the Congress for discussion, covering the fields of administration, production, distribution, personnel, agriculture, and home management. But a great deal of this material was nothing more than propaganda for or against various political regimes. There was much that might have been better said and even more that would have been better not said at all, though one must concede that many of the contributors may have been misled by the terms of reference which have been quoted.

It would have been well if more of the delegates had written their papers and speeches from the point of view so ably expressed by Lord Leverhulme in an address to the Congress. "We are all conscious," he said, "of the striking disparity between the world's actual consumption of goods and services and the potential powers of production with which science has now endowed mankind. Few of us, on the other hand, accept this situation as the natural and permanent result of the progressive application of science to all departments of our life and culture. We recognize our present troubles to have arisen to a large extent because our progress has been unbalanced and there has been a time lag between technological progress and progress in other departments of human endeavour. We recognize that the danger of our present situation lies not in the increasing impact of science on our lives, but in the uneven incidence of this impact. While productive efficiency has increased and continues to advance with bewildering rapidity, we destroy much of the possible advantage to be derived from this progress by the methods we adopt in our distributive machinery and in our dealings with our fellow men. As long as we continue to believe that the problem must be solved by the artificial creation of scarcity through restricting production, so long will the situation continue to grow worse."

The reason why the above approach to management problems was largely absent from the Congress was best expressed by Dr. H. C. Link in an excellent speech on the psychological foundations of management. "A few weeks ago", he said, "the steel companies announced their annual appropriations of about ten million dollars for research into the development and behaviour of steel. This is more in one year than has been spent in the entire history of psychology, since it became a quantitative science, for research into the development and behaviour of personality. . . . What are the results? One of the most obvious is this: while denying the possibilities of a science of man, almost every manager regards himself as an authority on human nature. Managers who consider themselves ignorant of the dynamics of machines nevertheless consider themselves, with no more scientific study, authorities on the dynamics of the emotions of man. The result has been a continuous conflict of personal opinions and the triumph of might rather than right, of expediency rather than truth."

It can be very easily understood from this, that a management conference is handicapped by the fact that there is so little concrete data to talk about and discuss, and wherever such a state of affairs exists there are bound to be numerous papers about nothing at all. A great deal of the general addresses were nothing more than orations on the merits of private enterprise, re-echoing time and time again old, familiar, and outworn phrases. In view of the fact that the Congress included delegates from the co-operatives of many countries and also from labour organizations, such speeches were thoroughly misplaced, and although the delegates listened with good humour, many of them must have felt that they indicated the presence of a terrible number of guilty consciences. But in spite of this, it was encouraging to find quite a few of the delegates expressing the view that managerial problems ought to be studied strictly from the professional aspects, and that their study is obscured by political contentions, selfish motives and class conflicts. A plea from Major Urwick that management problems should be approached from the scientific rather than from the nationalistic attitude was passed by without much consideration.

On the whole, it may be said that neither the papers presented at the general sessions nor the subsequent discussion were particularly noteworthy. Some of the papers dealt with management problems, but the majority were concerned only with technological procedures. The agricultural section, which stood in a class by itself in so far as quality was concerned, discussed a total of thirty-seven papers, of which seventeen dealt with purely technical matters such as the control of plant diseases, soil erosion, etc. Prof. John D. Black in some concluding remarks to this section said that "it is not difficult for one who has had contact with our agricultural colleges to understand how management in agriculture has come to be discussed in this segmentary way. . . . No satisfactory co-ordination of technology and social science has been achieved".

With regard to the other sections, very little can be said. The distributors spent three days discussing problems such as sales promotions, touch appeal, branded goods and more often still arguing about the meaning of the terms they were using. The consumer was in the forefront of all such debates, though he was talked about more as a victim than as one who is to be served The Swedish co operators, who had much to contribute to the general theme of improving on our present methods of distribution, as also some of the other foreign visitors, were given little opportunity or encouragement to take an active part in the discussions

Similar remarks could be made about the other sections

During the meeting The American Society for the Advancement of Management ' held a dinner for those attending the Congress, at which various New Deal administrators were invited to speak This was the only occasion during the week at which the New Deal was mentioned other than in derogatory terms From the point of view of the visitors from overseas this was the most instructive meeting for here alone was it possible to learn about things which they did not understand and to hear things which had been heard many times before

R M W TRAVERS

Research and Development in Glass Technology

New Laboratories at St. Helens

THE new research laboratories of Messrs Pilkington Brothers, Ltd at St Helens, opened by Sir William Bragg on October 5, represent a yet further stage in the scientific development of glass technology in which such striking progress has been made during the post War years At the luncheon before the opening ceremony Lord Cozens Hardy, chairman of the company, reviewed its progress , the firm has carried out glass manufacture at St Helens for more than a century, the first works chemist having been appointed in 1844 and the analytical laboratory dating from 1869 He referred to the high level of glass making which had been attained by chemical and technical skill in the early years of the century Not only was it known what types of ingredients and proportions were necessary to obtain high quality glass but also very considerable strides had been made in manufacturing refractories to stand up well to high temperature conditions without being unduly attacked by the molten glass Since the Great War, however, the manufacture of glass has largely been mechanized, necessitating very close control of the compositions and the temperature at which glass is melted and worked Out of the experimental investigations necessitated by this position there has grown a technical development department

Towards the end of 1936 the directors of Messrs Pilkington Brothers decided to supplement this work by forming a research laboratory, closely associated with which was to be a general analytical laboratory for control of the Company's products The new research department is intended to function in the more academic field of science and will, it is expected, frequently be responsible for fundamental work on first principles The problems with which the new laboratories will be confronted fall into seven categories, covering the melting of glass, the study of refractories, the processing of glass, uses of glass the properties of glass, methods of testing glass, and miscellaneous matters such as the production of mirrors to withstand rigorous weathering and temperature conditions, etc Lord Cozens Hardy referred to further advances in glass manufacture which are approaching completion, by which a ribbon of glass flowing out of a tank is passed successively through the annealing process and through a grinding and polishing machine which treats both sides simultaneously, the whole machine being more than 1,000 feet long Its use, it is believed, will once more completely revolutionize the manufacture of plate glass

Before cutting a glass silk ribbon across the doorway of the new laboratory, Sir William Bragg referred to the way in which in recent years the use of X ray methods has elucidated the ultimate structure of glass with some approach to completion The remarkable net like structure thus revealed has laid the foundation for a wholly new attempt to relate the physical and other properties of glass with its chemical constitution This fuller understanding of the constitution of glass has led to further control over manufacturing methods

The new laboratories have been built to the design of Mr Herbert J Rowse who also designed the United Kingdom Government Pavilion at the Glasgow Exhibition Together with the equipment, the cost of the new laboratories is about £40 000, and they are designed to house the director of research, Dr H Moore and a staff of forty seven including fifteen to twenty university graduates and about twenty five qualified technical assistants The laboratories are designed essentially to meet individual requirements and a novel feature is the use of glass bricks for the internal corridor walls Most of the physical laboratories are devoted to special instruments or special testing processes, and they include an X ray laboratory with a fully automatic X ray apparatus for the identification of crystals and the determination of the viscosity of glass Other laboratories are specially equipped for thermal expansion measurements, the determination of refractive index and hardness, the measurement of the bending of loaded glass beams, flatness testing and optical work Among the equipment of the latter is a photometer head integrating sphere for measuring the transmission of light through opaque glass and a Babinet strain viewer An annexe to the laboratory is devoted to high temperature work on refractories glass melting and toughening Among the apparatus exhibited was a stirring test designed by a member of the staff for comparing the merits of different materials for the construction of tank surfaces In this apparatus five fingers of these various materials, fixed into a flat circular plate are rotated vertically in a bath of molten glass at 1,500°

The main block of the research laboratories includes a large analytical laboratory and laboratories for general chemical research and organic research In addition the building includes a library, the furniture for which was made in Messrs Pilkington Brothers own carpentry and cabinet making shops The library already contains a nucleus of about 2 000 books, including a number of the earliest records of the firm dating from 1869 A number of striking examples of coloured glasses and fluorescent glass were shown in the laboratories Both the exhibits and the equipment of the laboratories fully justified Sir William Bragg s remarks as to the national importance of the inauguration of this new research institution

Fifth International Congress for Applied Mechanics

THE Fourth International Congress for Applied Mechanics was held at Cambridge England in 1934 and the Fifth very appropriately met at Cambridge, Massachusetts on September 12 16 The Congress was attended by more than four hundred members as the guests of Harvard University and the Massachusetts Institute of Technology More delightful hosts could not have been desired by the members who shared in the meetings and in the entertainments arranged by the local committee consisting of H M Westergaard, J P Den Hartog J C Hunsaker, L S Marks and H Peters

The Congress was opened by Prof K T Compton, president of the M I T acting as president of the Congress The work of the Congress was accomplished by means of technical sessions at which communications from members were read, by general lectures and by a symposium on turbulence The field of applied mechanics was divided into the following general heads (I) Structures elasticity, plasticity, fatigue strength theory crystal structure (II) Hydro and aerodynamics gas dynamics hydraulics meteorology, water waves heat transfer (III) Dynamics of solids, vibration and sound, friction and lubrication wear and seizure Simultaneous sessions of the three sections were held Abstracts of the papers presented were printed in English in the September issue of the *Journal of Applied Mechanics*, a copy of which was given to each member Communications were received from the following workers from the British Empire S Brodetsky L P Coombes, J N Goodier A A Hall, C F Inglis G J Klein, L M Milne Thomson, F F Relf E G Richardson D M Smith, A V Stephens J L Synge, and G I Taylor who gave a general lecture on turbulence The meetings were held at the M I T for the first four days and on the last day at Harvard University

On Monday September 12, members were able to be present at the dedication at the M I T of the Wright Brothers Wind Tunnel, among the speakers at the opening ceremony being G Brewer of the Royal Aeronautical Society The tunnel is a closed welded cylindrical steel circuit with a 2 000 h p electric motor and a variable pitch propeller in which the air can be compressed to four atmospheres giving a Reynolds number of 6 500 000 or exhausted to one quarter of an atmosphere, when a velocity of 400 miles per hour is expected to be attained The working section of this remarkable tunnel is an ellipse, ten feet by seven and a half feet

Apart from attending lectures and hearing papers read, one of the great advantages of an international Congress is the opportunity of scientific workers from different countries meeting personally and exchanging ideas in a quite informal fashion This opportunity was amply afforded by the receptions and conversaziones which were organized for each evening and contributed in no small measure to the success of the meetings The largest social undertaking apart from the final dinner was the excursion on Thursday September 15 to Middlesex School the route passing through Lexington and Concord, places famous in American history At the School a picnic supper was served an address on Galileo's Discorsi was given by Dean S H Hollister, of Cornell University and the proceedings were thereafter enlivened by a bonfire and a male chorus of Boston Negroes

Following the Congress members were invited to visit the National Bureau of Standards at Washington, D C, and the aeronautical laboratory at Langley Field, Virginia Many members availed themselves of this opportunity of seeing important scientific work in progress, and some very pleasant parts of the United States

New Laboratories of the Metropolitan Water Board

NEW Laboratories of the Metropolitan Water Board were opened by the Minister of Health, the Right Hon Walter Elliot, M P, on October 17 in the presence of a distinguished company They are situated at New River Head, Rosebery Avenue, adjacent to the Board s head offices, and replace laboratories in Nottingham Place, which have been in use since 1905

The Metropolis Water Act of 1871 provided for the appointment of a 'water examiner by the Board of Trade and in early days the water supplied by the London water companies was subjected to daily examination by Sir William Crookes and Profs James Dewar and Percy Frankland Under the Metropolitan Water Act, 1902, by which the several existing water companies were consolidated into one undertaking under the newly constituted Metropolitan Water Board, the Board was similarly placed under an obligation to conduct chemical and bacteriological examinations of its water

The Board in 1905 appointed the late Sir Alexander Houston to be Director of Water Examinations he died in 1933 and was succeeded by the late Lieut Colonel Harold In 1936, the Board approved a scheme for the erection of new laboratories, and Colonel Harold and the appointed architect, Mr Murray Easton, visited many laboratories in the United States in order to ascertain the latest developments in modern laboratory planning and practice The present building is the outcome of their inquiries but unfortunately Colonel Harold did not live to see its completion A descriptive booklet has been issued in connexion with the opening which contains views of the new building and of some of the laboratory interiors

The new laboratory block has a north south aspect and is built on a curved plan, the object of which was to allow more open space around, and to relate it to the existing head office block so that in case of extension the quadrant would strike the end of that building This construction not only produces a striking appearance architecturally, but also provides some thirty feet more space for the rooms facing north

The basement contains store rooms, cold, cool biological, and spare laboratories, cold room and refrigerating plant, air conditioning plant, motors, centrifuge and boiler room, and workshop The director s room is on the ground floor, with offices, library, photomicrographic room, biological, biochemical and bacteriological research laboratories The first floor houses wash rooms for apparatus preparation and sterilizing rooms for culture media the bacteriological laboratory and sub culture rooms and four constant temperature rooms for incubation All the top floor accommodation faces north and is allotted to the chemical section, with rooms for distillation, balances, stills and fume cupboards

The building is of brick with stone facings, and is steel framed Rubber flooring is used for most of the laboratories, and laboratory benches are in teak Vacuum and compressed air points are provided on the benches, also steam where required Access to the various floors is provided by a lift and a circular staircase housed at the east end in a circular tower like extension Full details respecting construction, fittings and general lay out are given in the booklet referred to above

---

University Events

BOMBAY —Dr K Venkataraman, reader in dyeing and printing, has been appointed Mody professor and head of the Department of Chemical Technology in succession to Prof R B Forster

CAMBRIDGE —The following appointments have recently been made. Dr R H Thouless, of Corpus Christi College, University lecturer in education, Dr J T Irving, of Gonville and Caius College, University lecturer in physiology, F R Berridge of Trinity College, assistant in research in radiology (diagnostic), Dr A Paterson, of the University of Edinburgh, assistant in research in psychiatry

The Research Committee of the Dyestuffs Group of Imperial Chemical Industries, Limited, has offered a research studentship to the University when the Company requires to encourage research of a particular subject The stipend will be £350 for two years, with a possible extension, the appointment to be made by the University, after advertisement if desired.

A R H Trim, of Trinity College, has been elected to the B W Levy studentship in biochemistry

Dr H G Sanders, University lecturer in agriculture, has been elected into a fellowship at St John s College

R Howles of St John s College, has been appointed to the Frank Smart studentship in botany

At Trinity College the following have been elected into fellowships Dr S A H Rushton, Michael Foster student, 1925, Stokes student, 1927, Gedge prize, 1928, research fellow of Emmanuel College 1930 University lecturer in physiology D J Bauer, for research in physiology Mr Bauer gained a double first in the Natural Sciences Tripos and was Michael Foster student in 1937 38 E R Love, for research in mathematics, Mr Love was a senior optime in Part II of the Mathematical Tripos and gained honours with distinction, in Part III, he was Smith s prizeman in 1937 W C Price, for research in physical chemistry

The Managers give notice that an election to the Pinsent Darwin studentship in mental pathology will be made in January 1939 The studentship is of the annual value of not less than £225 and is tenable for three years The student must engage in original research into any problem having a bearing on mental defects diseases or disorders, but may carry on educational or other work concurrently Further information can be obtained from the Secretary, Pinsent Darwin Studentship Psychological Laboratory Cambridge

LONDON The appeal for an endowment fund of £100,000, which was launched a year ago on behalf of the Department of Business Administration, at the London School of Economics in the University of London, has not yet achieved its full objects It had been hoped to raise a sum, the income from which would not only make the finances of the Department permanently secure, but would also enable it to carry out several much needed developments Further donations are urgently needed in order to achieve fully the purposes of the appeal The amounts so far subscribed will nevertheless be sufficient to ensure the maintenance of the Department on its existing scale for a further period of seven years, and university students who contemplate a business career and wish to devote a post graduate year to special training, may plan their studies in full confidence that the course will continue to offer at least the same facilities as hitherto

SHEFFIELD The following appointments have recently been made Dr G C Hampson, assistant lecturer in chemistry, J C Colman, assistant lecturer in zoology, E Baildon, assistant lecturer in mechanical engineering

The Council has received a notification of a bequest free from legacy duty, under the will of the late Mrs Lucy H Habershon in the following terms To the University of Sheffield any of my late husband s books on mining or kindred subjects which they may care to have and the sum of Three thousand Pounds for the purpose of founding or establishing a fund to provide Scholarships in Mining to be called 'The Matthew Henry Habershon Scholarships', and a further sum of One thousand Pounds for coal dust research work

Mr M H Evans has resigned his post of lecturer in physics, and Dr E Seddon his post of lecturer in glass technology and research physicist

Science News a Century Ago

The Zoological Society

At a meeting of the Zoological Society on October 23, 1838, letters from three corresponding members were read. M. Julian Desjardins, secretary of the Natural History Society of Mauritius, wrote saying that it was his intention to leave that island on January 1 of the following year for England, with a large collection of objects on natural history, many of which he intended for the Society; Colonel P. Campbell wrote from Alexandria that he had not yet succeeded in gaining any further information respecting the possibility of procuring some white elephants for the menagerie in Regent's Park, and Lieut.-Colonel Doherty, governor of Sierra Leone, wrote that he was using every exertion to procure for the Society a male and female chimpanzee.

Statue of Watt at Greenock

"The statue of James Watt, by Sir Francis Chantrey, is now placed in the building erected for it in Union-street. It is an 8 feet figure, of statuary marble, and weighs upwards of 2 tons, and the pedestal, which is of Sicilian marble, weighs about 3 tons. On the front of the pedestal is the following inscription, from the classic pen of Lord Jeffrey: 'The inhabitants of Greenock have erected this statue to James Watt, not to extend a fame already identified with the miracles of steam, but to testify the pride and reverence with which he is remembered in the place of his nativity, and their deep sense of the great benefits his genius has conferred on mankind. Born XIX January MDCCXXXVI. Died at Heathfield in Staffordshire, August XXV, MDCCCXIX.' On the right of the pedestal is a shield containing the Arms of Greenock, and on the left strength and speed." (*Mechanics' Magazine*, October 27, 1838.)

Airy's Compass Experiments

Throughout 1838, the Astronomer Royal, Airy, was much occupied with the improvement of compasses for iron ships, and, at the instigation of the Admiralty, in the summer made experiments in the steamer *Rainbow*. On October 5 he received an application from the owner of the iron sailing ship *Ironsides* to correct her compasses. He accordingly went to Liverpool where he, as he said, "made a very important improvement in the practical mode of performing the correction". On October 28 he wrote to his wife referring to the *Ironsides*: "I worked up the observations so much as to see that the compass disturbance is not so great as in the 'Rainbow' (35° instead of 50°), but quite enough to make the vessel worthless; and that it is quite different in direction from that in the 'Rainbow'—so that if they had stolen one of the 'Rainbow' correctors and put it into this ship it would have been worse than before." Again, on November 1, he wrote, "On Wednesday I again went to the ship and tried small alterations in the correctors. I am confident now that the thing is very near, but we are most abominably baffled by the sluggishness of the compass." Airy reported on his experiments to the Admiralty and on December 4 had an interview with Lord Minto, the First Lord of the Admiralty, and Mr. Wood (afterwards Lord Halifax), the secretary, but "they refused to sanction any reward to me". His experiments, however, led to a great extension in the building of iron vessels.

Societies and Academies

Paris

Academy of Sciences (*C.R.*, 207, 437–456, August 29, 1938).

H. Lebesgue: Equivalence of regular polyhedra.

P. Lejay: Method of calculation of the coefficients characterizing atmospheric obscurity. Variations of this obscurity in the neighbourhood of Shanghai.

A. Rosenblatt: Series of univalent powers in the circle of unity.

P. Lévy: Addition of definite aleatory variables of modulus one.

L. I. Gama: Additivity of the *accumulatif*.

H. Bizette, C. F. Squire and B. Tsaï: The transition point λ of the magnetic susceptibility of manganous oxide. Curves are given for the susceptibility at 7,000 gauss and 24,000 gauss from about 40° K. to ordinary temperature.

Mlle. M.-L. Allais: New measurements of the K spectra of arsenic (33), selenium (34) and bromine (35).

A. Dauvillier: The internal structure of the globe, and the genesis of the continents and oceans. An outline of a hypothesis, a feature of which is that the globe, while still incandescent, had five lunar seas which became the basins of the oceans. The atmosphere consisted of hydrogen and helium, and as the temperature decreased, the former reduced metallic oxides of the sial and formed water which eventually condensed and eroded away the lunar relief.

E. Lederer and Mlle. R. Glaser: Echinochrome and spinochrome. The former, a red pigment from the blood corpuscles of a sea-urchin, has been obtained in crystalline form; while the latter, from the violet spines of a sea-urchin, is formed from it by the substitution of a hydroxyl group for a hydrogen atom.

(*C.R.*, 207, 457–468, Sept. 5, 1938).

K. Menger: New basis for the development of the geometry of Bolyai and Lobatchefski.

R. Wavre: A method of Volterra and a theorem of Dive relating to fluid masses.

S. Nikitine: Experimental study of the photodichroism of cyanine.

J. Gautrelet and Mlle. E. Corteggiani: Liberation of acetylcholine from the acetylcholine complex of mammalian brain by cobra venom.

G. Ramon, A. Boivin and R. Richou: Obtaining staphylococcal toxin and anatoxin in a medium of definite chemical composition. The medium does not contain peptone.

(*C.R.*, 207, 469–480, Sept. 12, 1938).

R. Salem: Convergence of Fourier series.

F. Leja: Approximation of continuous functions by certain harmonic functions.

R. Dalmon: Study of the constitution of nitric acid by its absorption spectra.

H. Gault and E. Steckl: Research on the condensation of acyclic aldehydes with certain compounds containing the carbonyl group. Condensation of formaldehyde and acetaldehyde with cyclohexanone.

Mlle. M. Fourcroy: In *Pinus pinea* each convergent conserves its functional individuality during reduction.

Social Science Problems and Programme

WHEN the Council of the British Association meets next month it will have before it the approval by the General Committee at the Cambridge meeting of the recommendation to create a new Division to deal with the social and international relations of science So far during the century or more of its existence the work of the Association under the administration of the Council and subject to the approval of policy by the General Committee has been carried on through the Sections each dealing with a particular branch of science and meeting only once a year As is implied by the deliberate choice of the term Division the new organization is intended to operate on somewhat different lines being intimately affiliated with the Association but semi-autonomous Much preliminary work will be required before the precise form and activities of the Division can be determined but the main object of the Division to further the objective study of the social relations of science offers ample scope for undertaking research including factual studies on the organization of science and its social and economic relations for discussion of the social aspect of science the consideration of the public relations of science and for consultative work or as a co-ordinating centre and information bureau

The science of society is still embryonic and though the British Association may well prove to have taken a decisive step in accelerating its development even the main lines of organization or activity of the new Division will probably require some time to determine Apart from anything else the relative merits of various lines of work such as the actual initiation of research on particular subjects and the various possibilities in regard to consultative or co-ordinating work as well as to the importance of implementing means for bringing the findings of science more effectively before the general public must be determined before the new Division can well allocate its resources and activities Nor can it be indifferent to such recent developments as the founding of Nuffield College Oxford and the recently established National Institute for Economic and Social Research London

The extent and character of the investigations provided by such bodies will obviously be a matter of prime concern to the new Division in considering the initiation of any research project of its own In considering the initial activities of the Division however especially in regard to factual research the plan adopted by the Committee on Science and its Social Relations (C S S R) of the International Council of Scientific Unions should be of some assistance This Committee is endeavouring to collect material for the preparation of a report and of bibliographies on the social relations of science to be presented at the next meeting of the International Council of Scientific Unions in 1940 The report is designed to cover outstanding developments in the various branches of science new applications of science in human society the organization of scientific investigation and its application with summaries of interpretative work on the world picture as given by science and its social relations

In pursuance of this plan the Committee has approached national academies and a number of international scientific organizations for assistance by the supply of relevant information A number of correspondents have in this way been appointed to whom have been forwarded a questionnaire covering points in science in general and in special branches of science upon which information is required These questionnaires should be of value in framing the initial policy of the new Division of the British Association Obviously, as is implied in what has already been written, the Division should first have regard to the existing position of social research in Great Britain It must have before it accurate information as to the extent and resources of the research effort in this field Something of the nature of what may be termed a map of social research is called for at an early stage To meet this requirement the Division might well decide to attempt to develop co ordinating functions and activities and to establish a co ordinating committee or information bureau, and also to establish relations with institutions dealing with social relations of science at home and abroad

The required picture of research however cannot be limited to social research alone Its significance can only be assessed when it is seen in its proper perspective in the general map of research effort, both scientific and industrial For this reason, the Division might well consider implementing an inquiry into the nature extent and resources available for scientific and technical research in Great Britain generally on larger and more authoritative lines than the inquiry initiated some years ago by the Association of Scientific Workers

Acquisition of precise data in this manner is undoubtedly an essential preliminary if the new Division is to utilize to the best advantage such resources as may be at its disposal for factual research in social sciences Moreover, it can scarcely be doubted that apart from the researches actually initiated by the Division, its influence could most valuably be exerted to assist in such a reorientation or diversion of research effort from the physical to the biological sciences as has been urged by Prof W McDougall Dr Julian Huxley and others Such representations would gain immensely in authority if supported by data drawn from such a survey as we have indicated

The activities we have just suggested are of themselves likely to require the institution of effort or the establishment of organization to deal with many other matters contemplated in the memoranda submitted to the General Committee of the Association at Cambridge such as the establishment of consultative machinery, the supply of material for the information of the public, and so on Moreover, the appointment of research committees similar to those constituted by the various sections of the Association must be one of the functions of the Division

The initiation of research by the new Division requires, however, not only a survey of existing activities and resources but also the elaboration of an adequate plan of research It is not essential to assume that the Division should alone be responsible for the actual initiation of research One of its valuable functions, if it develops into the co ordinating institution that is desired, may well be that of providing an authoritative plan of research desirable in the social field, the execution of which in detail is carried out by consultation with the various research institutions as well as by research committees of the Division

What may be termed the research programme of the new Division might thus consist of a broad and long range plan conceived in relation to the needs and opportunities as revealed by the information available, which would form the basis of detailed programmes some of which might be executed by the Division itself and others by other institutions or some of the professional associations whose contribution at present is insignificant Possession of a broad and long-range plan would moreover, enable the Division to take the detached view essential if its recommendations from time to time regarding the diversion and re orientation of research effort are to carry due weight and authority

An admirable exposition of possibilities for basic research in this field has been given by Prof H Levy in a chapter on the scientific study of social development in his recent book A Philosophy for a Modern Man" Indeed, many of the features of social life which he enumerates as requiring quantitative measures constitute a programme which might with advantage be considered by the Division These variables fall into three main groups There are first the qualities which determine the technological level of the community within which group are included all types of business and industrial enterprise Then there are the qualities defining the physiological level of the population In this group are included all those factors that determine the conditions under which people live The third group comprises the qualities which define the cultural level of the population and includes all those mental and æsthetic qualities that thrive or are frustrated by the conditions imposed in the other two fields.

Prof Levy's approach is, indeed, very similar to that adopted by Lord Stamp in the programme of research outlined in his "Science and Social Adjustment" which also claims the attention of the new Division Prof Levy, indeed, reiterates in somewhat different form a number of Lord Stamp's proposals He suggests, for example, the construction of an index of the degree of research activity in the community, and sub indexes showing how this is composed of research in fields ranging from highly industrial and engineering to highly abstract, mathematical or logical He suggests further a special index to measure the degree to which research is directed towards destructive ends rather than constructive progress

Again, indexes are required to measure the general technical level of commodity production or the social waste in the distributive and productive processes, particularly in relation to the effect of intensive advertisement Similarly, it should be possible to establish some standard of maximum social efficiency in shelter and housing provided for the community at any given time This would imply a relative index of efficiency of housing and accommodation for various social classes Like Lord Stamp Prof Levy directs attention to the need for a fundamental study of invention clearing in relation to patents and some index which would take account of factors hindering the assimilation or development of inventions Technological unemployment is another topic presenting problems demanding quantitative study, while on the physiological side Prof Levy urges the elaboration of an index of physical fitness applicable not only to individuals but also to social classes, as well as an environmental index, a food value level based on the biological value of the food consumed by the individual, to be taken in association with the cost of living index figure, as well as a resistance index to measure the extent to which the individual can withstand the onset of various illnesses, diseases or epidemics

Here alone indeed there is outlined a programme which the new Division might at first well find overwhelming If, however, its organization and activities are conceived on broad, fundamental and long range lines, there need be no fear of its being so immersed in the detail of a few investigations that it fails to exercise the co ordinating and stimulating effect over the whole field that is desired So far as specific researches may be concerned, its contribution, apart from the formulation of a broad plan may well be in just those borderline problems, at the growing points of research in different departments of science which involve organized and many-sided efforts for their solution While, therefore the new Division may appoint research committees to report upon these and other matters, it will be desirable at an early stage to examine the data which must form the basis alike for a comprehensive plan of social research or for any representation designed either to re orientate research effort or to stimulate fresh effort in professional or other quarters

A History of Bacteriology and Bacteriologists

The History of Bacteriology

By Prof William Bulloch (University of London, Heath Clark Lectures, 1936, delivered at the London School of Hygiene and Tropical Medicine) Pp xii+422+16 plates (London, New York and Toronto Oxford University Press 1938) 10s 6*d* net

SINCE the appearance of Löffler's fragmentary and otherwise faulty "Lectures" in 1887, students of the history of bacteriology have had no guide-book to this intriguing and complicated subject They will all, therefore, welcome the present volume—written by the foremost living authority, who has lived through the heroic age and was personally acquainted with many of the heroes It is true he had given us a foretaste of his knowledge in the 'System of Bacteriology" (vol 1, 1930) published by the Medical Research Council but this larva is now metamorphosed into an imago which will surely serve the most exacting needs of historical students for at least another generation Though originally delivered—like Loffler's essay in the form of lectures, this final product is actually a well documented contribution to science

The book is divided into eleven chapters dealing respectively with ancient doctrines of contagion , *contagium animatum* , *fermentation* , *spontaneous generation and heterogenesis* , *putrefaction and putrid intoxication* , *pyæmia, septicæmia, and surgical sepsis* *specific element in disease* , *classification of bacteria* , *cultivation of bacteria* , *Pasteur's work on attenuation of virus* , *history of doctrines of immunity* These chapters are amplified by copious and detailed individual bibliographies (64 pages) and a concise international biographical dictionary (58 pages) of "some of the early workers in bacteriology"—which is as remarkable for its inclusions as for its omissions Sixteen inserted plates of portraits and other illustrative matter with two full indexes of persons and subjects round off the work

No man, living or dead, has ever before attempted to cover all this ground with the same thoroughness As the author says, in his short preface if the task had been easy it would not have been left so long undone Consequently this book is incomparable in every sense , and for this reason there is probably no man now alive who is competent to review or criticize it in its entirety The following remarks therefore merely record the impressions which it has made upon another and less experienced labourer in neighbouring historic fields who can make no claim to first hand knowledge of all the sources and materials which are here so ably expounded and summarized

My first impression—for what it may be worth after a single perusal—is one of unqualified admiration for the author's solid learning I was already aware, of course that he had studied the subject all his life, and I have ever admired and respected his dogged devotion to facts yet I now appreciate once more, as though they were something new, the sterling qualities displayed in this book The data are presented concisely and fairly , and the author's own comments and conclusions appear, to me, almost invariably just and judicious A young man could not have composed such a book, and few older men could have compressed their ripe knowledge and experience into so small a compass Yet there is here no parade of erudition most of the real work was obviously done—as it should be—before the book was written In other words, the recorded facts have been ascertained verified, and properly digested, before presentation Many a simple sentence in this treatise must have taken years to evolve

With so much to choose from, it is difficult to notice any one section particularly , but for my own part I find the chapter on spontaneous generation especially pleasing as it reviews most satisfactorily and adequately almost the whole of this complex and previously misreported subject The account of Pasteur's work—not only here but also elsewhere—is masterly.

In a work of this scope and size it is obviously impossible that no faults should be discoverable The half dozen typographical errors which I have noted should probably be laid to the charge of the printers (for example 'lave' for have' (p viii), 'penicillium' for '*Penicillium*' (p 92), 'Willnan' for 'Willnau' (p 417) etc) But a few other slips also require amendment Those old familiar friends "the two Janssens" crop up again, regrettably, on p 19 (Zacharias is properly styled Janssen because his father was named Johannes—*alias* Hans or Jan but Johannes was not a 'Janssen', but Zachariassen as Zacharias was his father In this case Janssen was not a surname but a patronymic) The statement, on the same page, that "the solar microscope invented by Leeuwenhoek was perfected by J N Lieberkühn in 1739" is incorrect for Leeuwenhoek never invented a solar microscope, and the prevalent belief that he used a concave mirror magnifier of the Lieberkuhn type appears to be based merely upon a misunderstanding of his own words and pictures It is also incorrect to say that O F Müller—the "great Danish naturalist", as he is rightly called—was born of German parents' (p 384) His father's family, it is true were German immigrants into Denmark , but his mother was a Dane (*née* Margrethe Henriette Udsen) The title of Le Leu's ' Life" of that singular character Dr David Gruby is not "*Le David Gruby*" (p 370) but "*Le Dr Gruby* I have noted a few other mistakes of the same order of triviality, but can detect none of major magnitude in matters with which I am specially familiar

Although it covers so vast a field, this 'history of bacteriology is primarily a history of the medical aspects of the subject and of those engaged in it Even on the medical side, moreover there is a striking omission those interesting and important organisms the spirochætes are barely mentioned The history of iron-bacteria, sulphur bacteria, nitrifying and other soil bacteria of great physiological and economic importance is also almost excluded Winogradsky (who was awarded the Leeuwenhoek Medal for his researches in 1935) is given three lines in the biographical section, but his work is practically ignored in the text I regret to note also that the earliest English observers and illustrators of bacteria have likewise been strangely overlooked Edmund King (1693), John Harris (1696), and the celebrated "Anonymous of 1703" were surely worthy of note Robert Hooke is included, however among the "early workers" in the biographical notices , but his observations on bacteria are nowhere recorded And it is a pity, I think, that quotations are not always given with the exact spelling, punctuation, and other typographical peculiarities of their prototypes (see for example the citations from Leeuwenhoek and Benjamin Marten) To my mind quotations—especially in a historical work—should always be given in their original form exactly But these are clearly trifles in comparison with the immense mass of accurate facts and critically sifted data here impartially recorded and analysed

This is manifestly an important book but one which as I have already indicated I am not competent to judge—indeed I should be the last man to judge or criticize it as a whole All who are personally acquainted with its author and who are truly interested in its theme must simply rejoice to see these mature judgements and records preserved in print for all time Some of us had previously been privileged to hear them—at least in part—more racily recounted by his own lips in his native Doric yet even those who have not had this advantage must now recognize that this work is the outcome of a lifetime devoted to the pursuit of naked truth Apparently nothing in it is given at second hand all its information is fearlessly and faithfully chronicled from original sources It is scientific history in the best historical tradition—accurate objective and honest—and can therefore be copied with complete confidence Consequently I foresee a great popularity for this monograph among lesser writers of historical sections and introductions to all manner of future articles Seldom can one buy such an almost miraculous haul of historical fish for half a guinea

Nevertheless this admirable book is not merely a paradise for poachers it will also be used and trusted and acknowledged by every serious student who henceforth attempts to explore any of the same territory and will undoubtedly remain an everlasting inspiration to all future workers Incidentally and appropriately it illustrates anew the truth in a saying of Leeuwenhoek (the first genuine bacteriologist as he is here justly acclaimed) that *de vrugten die in den herfst rijp werden langst konnen duuren* —those fruits which ripen in autumn can last the longest

Clifford Dobell

British Mosquitoes

The British Mosquitoes
By J F Marshall Pp xi + 341 + 20 plates (London British Museum (Natural History) 1938) 20s

IN 1920 the British Museum published a Handbook of British Mosquitoes by Dr W D Lang it set up a new standard in its figures attention to early stages and in other ways That book has now been replaced by Mr Marshall s which though it owes much to its forerunner is definitely a new book and in many ways an advance on extant works on mosquitoes It is a matter of some interest to notice that both these books have been written by men who might claim the distinction of being amateurs The author of the first a palæontologist was asked under the stress of war to produce a monograph on these insects The author of the second an engineer who found that salt marsh mosquitoes were uncomfortable neighbours turned his mind first to control and through that to scientific study

In 1920 the British list of mosquitoes included twenty species the present work includes twenty nine About half these additions are due to more careful collecting the remainder to the recognition of species previously undetected or not regarded as separate

The general structure of the book is on accepted lines Mr Marshall tells the reader how to recognize a mosquito and introduces him to classification and nomenclature One may feel perhaps that though this is well done it is scarcely necessary for it has been done so often before and a reader quite ignorant of mosquitoes is not likely to use this serious work as a primer The general account of the biology of British mosquitoes at all stages includes an ingenious calendar showing what stage of each species may be found month by month For some of the species this has been elaborated to show the seasonal occurrence of each of the four larval stages separately One may here remark on the ingenuity with which the author sets out information as tables and diagrams The account of the early stages of adults of British mosquitoes deals particularly with those anatomical points which are used in classification and the information is so full that one may separate the four larval stages of almost all the species There is no other part of the world for which this detailed information is at present available

Leaving general topics Mr Marshall then gives a review of the British Anophelines and Culicines In each of the descriptions attention is first directed to the chief distinguishing features of the adult the hypopygium and the larva In some cases a description of the pupa or of the egg has been included in addition This morphological information is followed by a short account of the life history ecology etc of the species concerned and also (in most cases) by a list of its British records The description of each species concludes with a brief summary of its foreign distribution This part of the work is fully and beautifully illustrated the majority of the text figures being by Terzi An account of methods of control and some general notes on biology bring the book to an end

It need scarcely be said that different authors would emphasize rather different parts of the subject The present reviewer thinks that the account of those races of *Anopheles maculipennis* which do not occur in Britain might well have been omitted particularly as the subject has received such full attention elsewhere It seems also that some reference should have been made to the British record of the yellow fever mosquito (*Aedës argenteus*) No one supposes that the insect occurs wild in Britain but there is a printed record of it being found in Epping Forest which should perhaps have been mentioned if only to point out that it might have been based on an error

The book as a whole is remarkably up to date even on matters about which many entomologists are not well informed such as the relation of species of *Anopheles* to malaria and the physiology of mosquitoes The great majority of the figures are line drawings by Mr Terzi many of them having already appeared in the previous book There are also some remarkably successful photographs of adult mosquitoes taken by the author and his assistant Mr Staley The few coloured plates are perhaps unnecessary and not particularly successful

P A BUXTON

Relative Abilities in Primitive Groups

Primitive Intelligence and Environment
By Dr S D Porteus Pp ix+325 (New York The Macmillan Co 1937) 15*s* net

DR S D PORTEUS has an honourable record of studies in the comparative psychological endowment and capacities common in different social groups It is therefore the more to be regretted that this particular book is rather hastily thrown together and falls far short of what should reasonably be required in any scientific treatise Two thirds of it consists in theoretical discussion and in interesting but superficial descriptions of the social and material environment of the various groups the members of which Dr Porteus has directly studied

In the theoretical discussion the author shows himself to be alive to the difficulties of the type of comparisons which he is attempting to make and he states those difficulties fairly and well But that small portion of the book which is devoted to facts is poor The evidence brought forward is not impressive in amount the methods employed —all consisting in the application of mental and physical tests —are not adequately described and the statistical form in which the results of the tests are presented is thoroughly unsatisfactory Very nearly half this factual section is devoted to a study of results secured from some form or forms of the author s well known maze test here treated without anything like sufficient justification as an index of capability to adapt to the demands of an encroaching white civilization If the test can be treated in this way it is certainly a most extraordinary thing to find that various groups of Australian aboriginals score more highly at it than do groups of Bantu natives But as only average scores are presented with no measure whatsoever of dispersion and no indication of the distribution of scores it is actually impossible to draw any sure conclusion

Other comparisons are made on the basis of psychophysical factors brain capacity right and left hand grip and right or left hand dominance of grip Apart from the fact that here also only average measures are presented nobody knows yet what conclusions if any of a psychological nature can be drawn from these particular characteristics

Finally there is a short chapter on Tests of Learning Capacity These are in this book rather a mixed grill They are made up of form board and assembling tests a footprints test—in which duplicate photographs of footprints on a dusty road have to be matched with the originals —tests of auditory and visual rote memory and a small battery of intelligence tests of the routine kind From the application of these little is concluded

Dr Porteus says that he will present the whole of the statistical detail later and fully Until he does so a final judgment of the value of his work as recorded in this volume must be suspended When he does so it is greatly to be hoped that he will consider fully what precise criteria both of a statistical and of a general psychological kind must be satisfied if the results of the application of psychological tests are to be used seriously for the purpose of comparing the relative abilities common in differently organized groups

The Reverse Notation

Introducing Negative Digits with Twelve as Base By J Halcro Johnston Pp x+74 (Glasgow and London Blackie and Son, Ltd , 1938) 3s 6d net

IN this interesting book the author explains a new notation which he has devised to remove the main defects of the Arabic notation The two main characteristics of the system, called the reverse notation, are the introduction of negative digits and the adoption of 12 as the radix or base The consecutive sequence of digits is written $\bar{6}$ $\bar{5}$ $\bar{4}$, $\bar{3}$, $\bar{2}$, $\bar{1}$, 0, 1, 2, 3, 4, 5, 6 so that any number like 8 is denoted by $1\bar{4}$, whilst $1\bar{5}4$ represents seven dozen and four The notation is applied to the ordinary rules of arithmetic and the author claims that the numbers of the reverse notation are balanced about their *centres of gravity* , which is not the case with the Arabic system

The whole scheme is undoubtedly very ingenious, but when judged impartially, there appear to be far more difficulties in the notation than there are disadvantages in the existing Arabic system The initial trouble that teachers have in introducing and working with negative characteristics in logarithms is well known Indeed, to arouse a true concept of a negative number is by no means an easy problem either in psychology or pedagogy Yet in the system before us, negative digits abound , for example, log $3 = 0\ 54\bar{4}0$, log $6\ \bar{3}35 = \bar{1}\ 320\bar{4}$, $\pi = 3\ 2\bar{4}5\bar{4}$ and on page 47, the number of days in the year is represented as $265\ 3\bar{1}\bar{1}\bar{6}3$!

The author fully realizes that the introduction of such a notation is far from being a practical proposition, but hopes that it will be judged by the principle of the survival of the fittest It is, nevertheless, very difficult to see how the system can first be introduced Are accountants, scientific and technical computors, business men, etc , expected to incur the expense of changing the basic notation upon which they have made their calculations for so long ? If they were sufficiently convinced of the advantages of the system to try the experiment, would this ultimately lead to the introduction of the notation into schools, where it should logically begin to evolve ? One wonders, however, in this eventuality, what the teachers of arithmetic, especially in primary schools, would say to such a suggestion F G W B

The Macaulay Institute for Soil Research

Collected Papers, Vol 1 Edited by Dr W G Ogg Pp 16+54 papers (Aberdeen Macaulay Institute for Soil Research, 1938) 21s

THE Macaulay Institute for Soil Research was founded for the purpose of studying possibilities of land reclamation on the Island of Lewis, and of raising the standard of agriculture and living of its inhabitants Sir Robert Greig states in the preface that, since the foundation of the Institute, which is in Aberdeen, and of its experimental farm near Stornoway, Lewis has become more than self supporting in milk and eggs, and fine pastures have appeared and are extending over the formerly worthless peat bogs The Institute has justified its existence, and has tended inevitably to extend its research activities beyond its original field of peat land reclamation

These fifty four reprints of papers by members of the staff indicate the steady growth in the scope of the Institute s work The Macaulay Institute is the only British station devoted entirely to soil research From peat studies it has branched out into the chemistry and physics of mineral soils and latterly into soil classification and survey One can trace in these papers the gradual evolution of a still incompletely formed Macaulay school of thought in soil science in which modern Russian and ancient Scottish beliefs are struggling for mastery The papers themselves naturally vary in quality , some have obviously been included in order to make the collection complete rather than for their intrinsic value, but, omitting these, a high standard is maintained It is noteworthy that most of the recently published papers deal with soil chemistry classification and survey, rather than peat land reclamation This indicates a welcome development Should Britain ever decide to take stock of its land the Macaulay Institute would have an important part to play in the stock taking This collection of papers shows that it is already equipped for the part and can play it without detriment to the original purpose for which the Institute was founded

Pyrenean Festivals

Calendar Customs Music and Magic Drama and Dance By Violet Alford Pp x+286+16 plates (London Chatto and Windus, 1937) 15s net

MISS ALFORD is well known as a student of the folk dance and song of European peasantry, but the Pyrenees is a region which in this subject she has made peculiarly her own province In this volume, æsthetically delightful, as well as scientifically valuable, she has reviewed the results of some years of observation on both sides of the political frontier among the inhabitants of the Pyrenean regions from Catalonia on the east to the Basque country in the west Nor has she confined her studies to dance and song, for she deals here with some remarkable forms of custom and magical belief which serve to throw light on the main theme

The ethnological character of the peoples, as well as the geographical conditions of their habitat, have made for an intense conservatism in the past, which undoubtedly has led to the preservation in the dances of religious and cultural concepts, which in their origin are probably older than anything found elsewhere at present in Europe Such, for example, is the remarkable cult of the bear , while an apparent transformation into animal form represented in the dance recalls the fact that it is in this country that there occurs the palæolithic painting of the animal-magician in the cave of Trois Frères of Ariège

Miss Alford s work is a veritable gold mine for evidence of survivals of primitive modes of thought, and as such needs no further commendation to students of folk lore and primitive religion

Diffusion und chemische Reaktion in festen Stoffen
Von Prof Dr Wilhelm Jost (Die chemische Reaktion, herausgegeben von K F Bonhoeffer und H Mark, Band 2) Pp viii+231 (Dresden und Leipzig Theodor Steinkopff, 1937) 20 gold marks

THE present book deals with a number of phenomena which are of importance in modern physical chemistry The chapters deal with diffusion processes in the solid state, irregularities in lattices (*Fehlordnung*) the elementary processes in solid reactions, tarnish and general reactions in the solid state Although the literature is fairly well covered, there is more emphasis on modern work, including English and American The field covered is limited, so that many topics such as recrystallization are excluded but those parts selected for treatment are chosen judiciously and are dealt with in a very critical and systematic way A good feature is the close relation which is established between the theoretical principles (which are very clearly stated) and the experimental results The book is a well presented and accurate survey of an interesting subject

Reagent Chemicals and Standards
with Methods of Assaying and Testing them, also the Preparation and Standardization of Volumetric Solutions and Extensive Tables of Equivalents By Joseph Rosin Pp x + 530 (London Chapman and Hall, Ltd, 1937) 30*s* net

THERE are comparatively few books which deal with the standards and specifications for chemical reagents and, if only for this reason, the treatise under review would be acceptable, it is, however, doubly welcome in that it provides the most complete treatment of the subject hitherto produced Nearly five hundred substances are listed, these including many of the newer organic chemicals and indicators Assays are provided in most cases for the major constituent as well as for the likely impurities, while tables are given of the maximum tolerance permitted for the latter There is also a useful section on the preparation and standardization of volumetric solutions, together with extensive tables of equivalents and gravimetric factors

A Note-Book of Tropical Agriculture
Compiled by Prof R Cecil Wood Second edition Pp iv+147 (Trinidad Imperial College of Tropical Agriculture, 1937) 5*s*

THIS is a small book that can be wholeheartedly recommended It is a development of a small compilation which the author made while he was in India, and now he has added the results of his experience in Africa and in the West Indies Of course, many of the data given have no special reference to the tropics but the really valuable part of the book is that dealing with tropical materials and especially with tropical crops, about which it is somewhat difficult to get information The book cannot fail to be of value to all who are proceeding to positions connected with agriculture in any part of the tropics H H M

Florae Siamensis Enumeratio
a List of the Plants known from Siam, with Records of their Occurrence By the late Prof W G Craib Edited by A F G Kerr Vol 2, Part 4 Vacciniaceæ to Styraceæ Pp 311–393 (Bangkok The Bangkok Times Press, Ltd, London Luzac and Co, 1938) 7 tcs, 12*s* 10*d*

STUDENTS of Asiatic botany will welcome the appearance of Vol 2, Part 4, of this work The Enumeratio was commenced in 1925 by the late Prof G W Craib, and since his death Dr A F G Kerr has carried on the work

The present volume, which is arranged on the Bentham and Hooker system, contains the families Vacciniaceæ to Styraceæ A glance at the names of the collectors and of the authors of new species shows how greatly we are indebted to Prof Craib, Dr Kerr and their co workers for our knowledge of the flora of Siam The issue of further parts will be awaited with interest

Nationalism and the Communal Mind
By Dr E Hanbury Hankin Pp xv+199 (London Watts and Co Ltd, 1937) 7*s* 6*d* net

DR HANKIN S approach to the problem of nationalism and his examination of the causes which underlie the sporadic and periodic outbursts of this expression of the communal mind, are of considerable interest to the anthropologist and the alienist Like other inquirers, he traces it to the blood bond, but in a different sense He associates it with the group of customs of primitive peoples at the head of which are cannibalism head hunting and the like, and behind which are the magical or mystical conceptions of assimilation of power, whether from enemy or friend In support of the contention that primitive ideas of this type may survive deep down in the subconscious of the communal mind, the sporadic resurgence of cannibalism and other forms of the blood lust would appear to lend a measure of support

Die Leuchtmassen und ihre Verwendung
eine Einfuhrung in Fluoreszenz und Phosphoreszenz der festen Körper Von Dr Henriette Rupp Pp vi+163+2 plates (Berlin Gebruder Borntraeger, 1937) 8 gold marks

PHOSPHORESCENCE has so many modern applications and is of such fundamental significance in connexion with the theory of the solid state, that the appearance of this well written and comprehensive account of it is very welcome Dr Rupp describes the methods used to excite and analyse phosphorescent light, and gives an outline of the principal uses of phosphorescent bodies and the theories of phosphorescence Her book is particularly valuable from the orderly way in which phenomena are classified, permitting of quick reference to any particular aspect of the subject, and for the detailed accounts provided of the preparation of some materials of technical importance It includes a short history of phosphorescence, and a bibliography of recent publications

Oceanography and the Fluctuations in the Abundance of Marine Animals*

By Dr Stanley Kemp, F R S

A MOST important feature of animal life in the sea is the constant occurrence of large variations in abundance and these though they may not be greater appear to be more general in their incidence than in land animals One year may be exceptionally favourable with production far above normal to be followed perhaps by several years of scarcity and it is not uncommon to find that fish belonging to one year class are fifty times as numerous as those of another It is on these great variations in abundance that fishery prediction is based

Some very valuable information on fluctuations in year classes of fish has recently been collected by the International Council for the Exploration of the Sea The object of the Council was to summarize data on good and bad survival years in some of the principal food fishes and the reports from the specialists who were appointed to undertake the work are of particular interest For some fish the available information was found insufficient but for cod haddock herring and plaice the data are adequate at least for some areas The results show that in different parts of the north east Atlantic there are with rare exceptions no coincidences in good or bad spawning seasons even if one species only is considered and the evidence thus is that the fluctuations which are observed are regional in their incidence

Of recent years however it has become increasingly apparent that in addition to the annual fluctuations there are other over riding influences at work which not only affect the abundance of marine animals but also may bring about great changes in their distribution For the past thirteen years Mr F S Russell has been studying the young fish taken in the plankton at Plymouth and has made regular collections by standard methods in the neighbourhood of the Eddystone He finds that from 1931 onwards there has been an alarming decrease in the abundance of larval fish At first this decrease occurred in the comparatively small number of summer spawning fish but it has now extended to the spring spawning fish also If we compare the average numbers for the four year period 1934 37 with those for the same period ten years ago 1924–27 we find that the larvæ of summer spawning fish have now been reduced to little more than one fifth of their former abundance while the numbers of the young of spring spawning fish have dropped to one third It is particularly to be noted that all species of fish are similarly affected and bearing in mind the evidence I have already mentioned on good and bad survival years this fact alone is sufficient to show that the decrease is not due to a chance coincidence in annual fluctuations

This change which has come about in recent years is unfortunately apparent also in the Plymouth herring fishery which has declined to such an extent that it is now virtually non existent As with herring fisheries elsewhere the catch has shown marked fluctuations—the seasons 1924–25 1927 28 and 1929 30 were much above the average These however are normal annual fluctuations and they are due as Mr Ford has shown to the great abundance of five year old fish there were specially successful spawning seasons in 1920 1923 and 1925

The significant feature is however the marked change in the composition of the catch which began in 1931 32—that is to say in the winter of the year in which the summer spawning fish larvæ showed their first signs of decline Prior to 1931–32 the younger herring not more than six years old always formed at least two thirds of the catch In that season the younger fish were only 52 per cent of the total and from then on there has been a rapid deterioration until to day there are less than 20 per cent of the younger and more than 80 per cent of the older

The change found by Mr Ford in the constitution of the herring shoals was not immediately reflected in the size of the catches which for some years were maintained at a good level by the considerable stocks of older fish But as these passed out they were not replaced by any adequate numbers of the younger year classes and in recent years the fishery has been profoundly affected Formerly the number of Lowestoft drifters which visited Plymouth for the herring season rarely fell below 75 and was sometimes well over 100 during the past season only one came

---

*From the presidential address to Section D (Zoology) of the British Association, delivered at Cambridge on August 18. The complete address contains several tables of data upon which the argument is based.

It is interesting and perhaps significant to note that, as Mr G P Farran has shown the stock of herring on the north coast of Donegal has shown a pronounced decline in recent years The decline began in 1930, some eighteen months before the change in the constitution of the Plymouth shoals was first seen and the industry based on this fishery has suffered greatly Mr Farran tells me however, that the shortage of herring in recent years has been accompanied, just as at Plymouth, by a great reduction in the numbers of the earlier year classes and it is thus possible that the same long period fluctuation is affecting both areas

FACTORS IN LONG-PERIOD FLUCTUATIONS

Since 1931, when the depression in the Plymouth area began there has been a marked change in the amount of phosphate in the offshore waters Records made by Dr W R G Atkins and Dr L H N Cooper show that the phosphate is at its maximum in the winter in December and January, and since the phytoplankton crop is limited by the amount of phosphate in the water the winter records give a good indication of the quantity of food which will be available for fish larvæ The records show a heavy decrease in phosphate beginning in 1931 If the average values for the two four year periods 1924–27 and 1934–37 are compared, we find that the decrease has been about 35 per cent The fact that the larvæ of summer spawning fish were the first to feel the adverse conditions and that those of the spring spawning fish were not seriously affected until 1935, can in theory at least be explained in terms of nutrient salts a reduced crop of phytoplankton will mean a smaller supply of zooplankton and this will mostly be consumed by the spring larvæ leaving little or none for those that come later in the year

Renewal of the phosphate in the Channel appears to be largely dependent on an inflow of mixed Atlantic water which is rich in phosphate because it contains water that has upwelled at the edge of the continental shelf and it seems probable that the normal water movements off the mouth of the Channel have undergone marked alteration in recent years Direct proof of this is lacking, for we have no observations in the waters to the west of the Channel but evidence of it is afforded by the very interesting discovery which Mr Russell has made that certain planktonic species may be used as indicators of water masses A relation of this kind has been found in a number of plankton species, but it is here only necessary to refer to those belonging to the genus *Sagitta*, and these owing to their abundance are the most useful

Of the species of *Sagitta*, *S serratodentata* is typical of the open Atlantic, *S elegans* of the mixed Atlantic water and *S setosa* of the Channel water The first of these is only to be found on rare occasions off Plymouth when the inflow of Atlantic water is exceptional Mr Russell's data only began in 1930, and the records are therefore not as complete as could be desired It is however, known that for some years prior to this date the offshore plankton in the neighbourhood of Plymouth was of the kind characteristic of the mixed Atlantic water it was a very rich plankton with such forms as *Meganyctiphanes* and *Aglantha* It was this type of plankton which was found in 1930 and in the regular series of tow net hauls made in that year, Mr Russell found that there was 94 per cent of *S elegans* and only 6 per cent of *S setosa* In the following year when the deficiency of phosphate and of summer spawning fish larvæ first became manifest, there was a conspicuous change in the *Sagitta* population of *S elegans* there was only 17 per cent, while there was 83 per cent of *S setosa* Since then *S setosa* has always greatly preponderated in the catches with a percentage of 93 or more with the single exception of 1936, when there was 60 per cent of *S setosa* and 40 per cent of *S elegans* There is no doubt there was a small incursion of mixed Atlantic water in the Channel in this year, but it was apparently insufficient to alter the trend of events

We thus have evidence from four separate sources of the changed conditions which have prevailed in the Channel since 1930–31 These sources are (i) the winter phosphate maximum, (ii) the numbers of fish larvæ, (iii) the constitution of the spawning herring shoals, and (iv) the predominance of one or other species of *Sagitta* The picture, to my mind at least, is convincing one gains the impression that if only we had fuller knowledge corroborative data from many biological sources would be forthcoming

We may suppose that this long period fluctuation at the mouth of the Channel will end in due course but we have no means of knowing when this will happen When the change comes it will be heralded, we believe, by the return of *Sagitta elegans* in large numbers, and by a marked increase in the winter phosphate maximum The fisherman will presumably not find any immediate improvement in the bottom fish As yet he has perhaps scarcely realized the full extent of the depression which started some years ago, and when there is a return to better conditions, he must wait until the increased numbers of larvæ grow to fish of marketable size It is possible, however, that bottom living fish have been migrating into the area and that he may thus in some measure escape the worst effects of the depression If the younger herring have forsaken their spawning grounds and gone elsewhere we may hope that they will at once return in force when conditions improve and that the Plymouth fishery will rapidly be re established If however they have throughout held to their former migration routes and the present dearth is due to lack of suitable conditions for the larvæ, they are in the same position as the bottom fish and a number of years must elapse before the fishery can be resumed

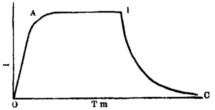
(*To be continued*)

Luminescence

An important series of discussions arranged by the Faraday Society took place in the Biochemical Theatre of the University of Oxford on September 15–17 on the subject of Luminescence A more appropriate time for the discussion of work in this field could scarcely have been chosen and in spite of recent events a surprisingly large number of visitors from overseas was present The discussions were formally divided into three parts luminescence of vapours liquids and solutions luminescence of solids chemiluminescence The subject of luminescence is of particular interest at the present time for two reasons First it forms an excellent testing ground for some of the more recent theories particularly with respect to the physical properties of solids and the nature of chemical reactions Secondly a good deal of stimulation has been given by the technical interest in the subject The use of fluorescent solids in discharge tubes as a means of modifying the colour of the light or increasing the efficiency of such devices is undoubtedly leading up to new work of interest and contributions to the meeting were made by more than half a dozen industrial laboratories

The first two parts of the discussion dealt essentially with the absorption of radiation by matter and its emission in the form of light the final section was concerned however with the radiations emitted as a result of chemical reactions The now classical experiments of Polanyi and his collaborators on the characteristics of the reaction between streams of halogen and sodium vapour at low pressure are a specially interesting example of chemiluminescence in that they are providing the basis for theoretical work in this field

A valuable feature of the earlier parts of the meeting was the way in which ideas concerning the precise meaning of the terms fluorescence and phosphorescence were brought out If a luminescent compound is first illuminated at *O* (see accompanying graph) with radiation of constant intensity, an appreciable time may elapse before the luminescence reaches a constant value as along *AB* If the exciting radiation (for example ultra violet) is removed at a time corresponding to *B* a rapidly falling curve of intensity *BC* follows Many and in fact most of those engaged in experimental work in this field have usually referred to the part *AB* as fluorescence and the part *BC* as phosphorescence This usage is undoubtedly convenient from the experimenter s point of view since the time constant of the luminescence has usually been measured during the period *BC* It has of course been realized that the electrons returning to the ground state during the equilibrium period *AB* do so only after a finite and possibly considerable time after the absorption process It was suggested in the course of the discussion that definitions based on the type of electron transition would be more fundamental than those already described On this basis the term fluorescence should be reserved for all processes in which electrons are returning from *excited* energy states of parent atoms and the term phosphorescence used only in those cases where the luminescence is dependent on temperature and is a result of electrons being involved in metastable states or completely removed from the parent atoms It is likely that the older definitions will continue to be used on account of their convenience and because of insufficient data concerning processes Further progress along these lines can only be made by a study of the time dependent effects of luminescence and the corresponding photo conductivity properties



Very many substances both liquid and solid are capable of absorbing some part of the ultra violet spectrum but comparatively few are luminescent It is to be assumed that the non luminescent substances convert this absorbed energy into heat in the form of elastic vibrations of much smaller quanta than visible light, and the important theory of Peierls developed some years ago on the problem of radiationless transitions in solids is now receiving much attention This problem of radiationless transitions is of obvious importance to all branches of the subject In liquids and solutions, for example the fluorescence may be 'quenched' by increasing concentration of the luminescent centres, or by the addition of oxygen The problems associated with the quenching of luminescence by a close coupling between the excited molecules and the surrounding solvent on one hand, and the question of internal quenching on the other, were made clearer by pictorial representation in intersecting curves of potential energy as a function of atomic or molecular separation The work on liquids is concerned chiefly with organic solutions and the complexity of the problem involved is shown by the fact that some organic solids show a large drop in the quantum efficiency of fluorescence when put into solution, while others show an equally sharp rise

Almost a whole day was given up to the discussion of luminescence in solids and on the whole this was the most successful feature of the meeting It is now clearly recognized that there are two chief classes of luminescent solids The more restricted class contains pure solids and it is sometimes possible to recognize these by the fluorescence of their solutions , notable examples of this kind are the uranyl salts the platinocyanides, and certain rare earth compounds The fluorescence in the first two examples appears to be associated with co ordination groups , in the rare earths the sharp line spectra are connected with transitions within the 4*f* shell, but it has not been explained why only certain of the rare earths are fluorescent

Most luminescent solids, however, owe their properties to the deliberate addition of some impurity But between the two well defined groups of pure and deliberately impure solids are a number of others, the cause of luminescence in which is still in some doubt Zinc oxide, for example fluoresces in the near ultra violet with an easily recognizable spectrum and while it is assumed that the luminescence is linked up with the 'self impurity of excess zinc, no direct proof of this has yet been obtained The presence of *foreign* metal atoms in a solid may be made a matter of direct spectroscopic or chemical test, but other means will have to be adopted in cases such as that of zinc oxide Calcium tungstate is also fluorescent when free from other metallic impurities, and it has been suggested that the WO_4 co-ordination group is of fundamental importance to the luminescence , it may well be, however, that the excess or defect of one of the lattice constituents has a bearing on this problem also 'Pure' zinc sulphide presents a problem of even greater difficulty Zinc sulphide has been prepared by several workers during the last few years in a state apparently free from foreign metallic impurity, and the fluorescence is a bright blue The precipitation of zinc sulphide free from oxide is, however, a matter of great difficulty if not impossible, and experiments have yet to be carried out to prove whether the luminescence is a property of the pure ZnS lattice or of a lattice containing (*a*) excess zinc or (*b*) some oxygen replacing sulphur atoms These points have been mentioned merely to indicate that the problems of interpreting the luminescence of solids are by no means confined to the theoretical side

The discussions at Oxford showed also the importance of low temperatures in the investigation of luminescence in solids The spectra are apart from a few exceptions generally of a continuous nature at room temperature The use of temperatures in the neighbourhood of 90°–20° K has shown that many new features may be brought out, either in resolution, or in the comparison of various substances with a common activator In quite a number of solids luminescence is apparent only at these low temperatures The difficulties of measuring the absorption spectra of solids in powder form are well known, but the discussion brought to light a new technique that will doubtless be of value in this field Single crystals will, when obtainable, be of value, but the distinction between surface and volume luminescence was emphasized as a point of importance

The theoretical aspects of this part of the discussion were of value in making clear the advance in ideas from the rather restricted zone theory as applied to semi conductors a few years ago On this theory the sharp energy levels of an isolated atom were converted in the solid to a series of possible energy bands, separated by 'forbidden regions In a pure insulating solid, it might be possible to raise an electron from the highest full band to the next possible empty band When this happened, the electron would be free to move through the crystal under an applied field , such a case would correspond to the ionization of the parent atom, and the recombination of the electron with its positive 'hole' would give rise to the emission of radiation The advance in theory is concerned with a possible series of excitation levels lying between the highest full band and the lowest conduction band The 'forbidden' zone on these ideas no longer exists in simple form, and it is possible, as might be expected, to excite electrons in solids without making them free for photo conduction An important feature of the newer theoretical ideas is that it should be possible to distinguish between excited and ionized atoms in the solid by tests on photo conduction and on phosphorescence In the simplest cases the phosphors with a hyperbolic decay law should be photo conducting, while those with exponential decay laws should not The well known high efficiency of alpha particle excitation of luminescence in zinc sulphide phosphors, it was pointed out, is not due to the absorption of energy by the whole lattice and its subsequent transfer to the activating impurity atoms, but to the production of numbers of fairly high energy electrons (δ rays) colliding directly with the impurities

The last part of the meeting was occupied with chemiluminescence, which is usually concerned with the production of light during chemical reactions, more recently, it has been shown that some reactions produce feeble radiations in the far ultra violet Bioluminescence is now generally regarded as a chemiluminescence in which the luciferin is oxidized in the presence of molecular oxygen and the enzyme luciferase The work of Polanyi and Evans on sodium and chlorine vapour reactions is typical of one type of chemiluminescence and indicates that the production of light is a consequence of the following steps

$$\begin{aligned}
\mathrm{Na} &+ X_2 = \mathrm{Na}X + X\\
X &+ \mathrm{Na}_2 = \mathrm{Na}X^* + \mathrm{Na}\\
\mathrm{Na}X^* &+ \mathrm{Na} = \mathrm{Na}X + \mathrm{Na} + h\nu
\end{aligned}$$

where X is Cl Br or I, rather than one involving a neutral halide molecule and an excited sodium atom Bawn has recently extended this type of work to reactions involving organic halides such as CH_2Cl_2, $CH_3CCl_2CH_3$, etc

The other type of chemiluminescence to be discussed was the oxidation process appearing in the luciferin reaction already mentioned, the oxidation of the Grignard reagents the dimethyldiacridylium salts and many others Two methods of approach were apparent at the discussions Weiss adopted the more physical method and discussed the cases where the chemiluminescence can be regarded as the reverse of photochemical dissociation ($A + B \rightleftharpoons AB + h\nu$) and the quantum conditions associated with this type of reaction Drew, on the other hand has attacked the problem of chemiluminescence in the phthalic hydrazides from the purely chemical point of view of investigating the reactions that lead to their formation, the effects of the nature and position of substituents, and the interaction of the hydrazides with hydrogen peroxide

The discussions as a whole were of value in making clear the precise nature of some of the important problems to be solved and both the official meetings, and the more informal exchanges of views that inevitably take place on occasions of this kind played their part

J T Randall

The State and Medical Research in Great Britain*

THE annual Harveian Oration was delivered by Sir Edward Mellanby, secretary of the Medical Research Council, on October 18 at the Royal College of Physicians, London, the subject of his discourse being "The State and Medical Research"

Sir Edward first paid a tribute to Harvey, who "stands out as one of the greatest investigators, and his work—a wonderful combination of observation and experiment—is an example of the finest achievement of the human mind" Harvey's election in 1630 as physician in ordinary to Charles I brought him into close association with the head of the State, and one result of this association was permission to make use of deer and other animals in the royal demesnes for study—probably the first instance, with certain legendary exceptions, of State support for medical research Harvey's example has induced more and more individuals to take up research, and the revolutionary changes in medicine during the past sixty years only increase the appreciation of his foresight and skill These revolutionary changes include the introduction of new methods for the diagnosis, treatment and prevention of disease, the enormous increase in hospital accommodation the formation and development of the clinical laboratory and radiological department and the expansion and multiplication of the public health services

Increase of knowledge has been mainly responsible for these developments and it has come to be realized that health and disease are not conditions conferred upon man for his humble acceptance, but that by a certain method (Harvey's method) disease may be controlled and death itself warded off, and more and more men and women proceed to investigate and to accumulate knowledge

The acceptance in Great Britain of the new urge for research has been comparatively recent The late Earl Balfour said in 1896 "I have all my life been an ardent believer in a cause which is often laughed at—the cause of the endowment of research I think there is no branch of knowledge in which it may find a more useful field of application than in that of advancing medical knowledge " Again, in 1900, Earl Balfour pointed out how meagre was the equipment for medical research in Great Britain compared with Germany, France, Switzerland and Italy Medical research in these countries was undertaken for its own sake, and not necessarily for the elimination of disease though the leaders of industry there and in the United States soon realized that it was to their advantage to devote some expenditure to the furtherance of research

---

* Substance of the Harveian Oration before the Royal College of Physicians, delivered by Sir Edward Mellanby, K C B F R S on October 18

It has been said that Great Britain needed the stimulus of the Great War to realize the importance of research, resulting in the setting up of the Department of Scientific and Industrial Research in 1915 Actually, the Medical Research Committee came into being somewhat earlier, in 1913, under the National Health Insurance Joint Commission, to administer funds provided by the National Insurance Act of 1911 This arrangement terminated in 1919, and in 1920 the Medical Research Council took the place of the Committee, funds for the work of which were provided directly from the Treasury in the form of a Parliamentary grant in aid

Sir Edward Mellanby then discussed the possible sources that might be anticipated for the endowment of research, medical or industrial Had funds, private or otherwise not been available, such men as Darwin, Newton, Humphry Davy and Faraday could scarcely have pursued their work and made their discoveries On the other hand, it is true that some of the best work has been done by those labouring under conditions of extreme simplicity, notable instances being those of Claude Bernard and Louis Pasteur Endowment of research, medical or industrial, by private individuals has been the exception in Great Britain, but the American record in this respect during the past twenty years has been a fine one, and the extensive support given to British medical research by the Rockefeller Foundation may prove a stimulus to private munificence here, of which the Nuffield scheme at Oxford is possibly an indication

The ability to discover, Sir Edward remarked, is present in all grades of society , but the real discoverer is rare in all classes, and it should be the object of civilized communities to find him and to foster his activities Failing adequate private endowment, all will agree that there is justification in Great Britain for State support for research State support must, however, be associated with State control, a condition disagreeable to many owing to the fear of loss of freedom for the investigator History, however, has clearly demonstrated that State endowment is compatible with the best type of medical research, and indeed Sir Edward stated that one of the main objects of his discourse was to show how State control of medical research can be associated with freedom to the investigator

It is true that State control may have certain dangers, such as political influences, implicit in any State activity , not only has political influence been absent, but even political interest has been uncommon in the affairs of the Medical Research Council While Parliament possesses ultimate control, the Council has been given great latitude in its policy and finance, and the disposal of the funds supplied is at its complete disposal Of the present eleven members of the Council, eight are chosen for their scientific and medical attainments, each one approved by both the Lord President of the Privy Council and the president of the Royal Society political influence has had no detrimental effect upon the medical researches controlled by the Council A safeguard against bias and dictatorship on the part of the Council is the fact that there is constant change of personnel, each individual term of office being limited to four years

The appraisal of a new discovery is clearly difficult and mistakes are inevitable from time to time, it is seldom in the facts of a discovery, but rather in their interpretation, that mistakes are made, and in the Council's work more mistakes are due to benevolence than to harshness

After this statement of the case for State support of medical research, and vindication of its impartiality in Great Britain, Sir Edward proceeded to describe the general principles guiding the actions, and the work, of the Medical Research Council For general guidance of detailed work, the Council relies on the advice of special committees, of which there are twenty-seven at present, some being appointed conjointly with other bodies, for example with the Royal Society of Medicine (anæsthetics), the Lister Institute (vitamins), the British Empire Cancer Campaign (radiology) and others The Industrial Health Research Board, a subsidiary of the Medical Research Council, also receives advice from committees dealing with its problems The services of all members of these committees are given voluntarily Sir Edward also paid a tribute to the willing co-operation of the Royal Colleges of Physicians and of Surgeons

With regard to finance, the present annual income of the Council amounts to about £220,000, of which the State contributes £195,000, a sum that has recently been criticized as being meagre in view of the possibilities through research of the reduction of expenditure on the country's toll of sickness, which costs the Government between 200 and 300 million pounds annually In addition, private funds held by the Council contribute £13,000 per annum, and a sum amounting to £12,000 is derived from grants made by certain bodies for special purposes, including the Rockefeller Foundation, the Leverhulme Trustees, the British Empire Cancer Campaign and others

The principal factor limiting research activity is personnel, and one of the endeavours of the Council is to increase the number of research workers, but more funds will be necessary when more trained investigators become available Some system is also required for financing sudden important calls for organized research when these arise

The Council has also established and maintains the National Institute for Medical Research at Hampstead and Mill Hill, supports a growing number of research units both clinical and laboratory, and provides grants for individual workers At the National Institute for Medical Research, under the direction of Sir Henry Dale, work is done in two main divisions, one including researches coming under physiology, pharmacology, and biochemistry, the other those under experimental pathology and bacteriology Here in addition to research, the standardization of biological products, such as antitoxins, certain drugs, vitamins, and hormones, is undertaken, whereby the exact strengths of these products may be described in terms of units, and the doctor is thus able to prescribe known amounts of their active principles

The Medical Research Council also maintains at the Lister Institute a National Collection of Type Cultures, so that any medical man in the world can obtain at nominal cost a culture of almost any known micro organism At the Pathological Laboratory of the University of Oxford a Standards Department is maintained, from which preparations of bacterial suspensions and sera are supplied for use in the diagnosis of diseases, such as enteric and undulant fevers, and dysentery

The placing of units of research in different institutions has developed with much success in recent years The Council provides the salaries and the actual cost of the research the institution furnishing the accommodation There have thus been established the neurological research unit at the Hospital for Diseases of the Nervous System, Queen Square London, the research department on puerperal infections at Queen Charlotte's Hospital, London, the clinical research department at University College Hospital, London, and others Research grants to individuals are also made, such personal grants being usually limited to three years, and the worker is given full freedom to develop his problem A third activity of the Council is the award of travelling fellowships in research, and a number of the younger medical men of Great Britain have been past holders of those fellowships Assistance is also given to Government departments on problems of health and disease

After some remarks regarding initiative in research, and a reply to criticisms respecting the type of medical research supported by the Council, Sir Edward Mellanby had something to say about the future, observing that the difficulty he foresaw was not that of obtaining knowledge, but of its application to human needs He concluded his oration by pointing out that it is the function of the Medical Research Council to promote discovery, not to implement its application He made an appeal to the Royal College of Physicians of London suggesting that the College as a body and through its fellows and members might use its prestige and influence in guiding the profession and the public to appropriate action if such be needed, when scientific discovery has supplied new knowledge of importance to public health Finally, he submitted that the entry of the State into the field of medical discovery has been both stimulating and fruitful

Obituary Notice

Sir Basil Mott, Bart, C.B, F R S

BY the death of Sir Basil Mott on September 7, a pioneer in engineering practice, the Royal Society loses one of the few engineers who have been admitted to its fellowship He formed a link—one of the very few remaining—with those great figures whose names became almost household words in the latter part of the nineteenth century as the creators of outstanding engineering works—Benjamin Baker, Wolfe Barry, Charles Hawksley, Douglas Fox and others When a young man he gained experience, as a mining engineer, in work underground, which was invaluable in the pioneering work involved in deep tunnelling with the Greathead shield, the use of which has revolutionized the solution of transport problems in crowded cities The first use of this method on a large scale was in the construction of the City and Southwark Subway', which formed the first part of the 'City and South London Railway' and was taken in hand in October 1886 Basil

Mott became assistant to Greathead on this work and, so much was his skill and energy relied on, that he became Greathead's partner. He had the further valuable experience of operating the railway for the first eighteen months after it was opened in December 1890.

The difficulties attendant on maintaining electric traction underground—the first time that this had been attempted—were such as to call forth to the utmost Mott's natural ingenuity and resource, and this experience proved invaluable when, some years later, he joined Sir Benjamin Baker for the construction of the Central London Railway, the first Twopenny Tube from Shepherd's Bush to the Bank which was opened in 1900. These works and others which followed were the means of establishing the practice of deep tube tunnelling as an engineering method, and the process was thereafter applied in many other cities throughout the world, where it is probable that the public who make daily use of the transport facilities provided, have little recollection of what they owe to British engineering practice in general, and to Greathead, Baker and Mott in particular.

Mott was, however, a civil engineer in the widest sense, and there are few branches of the profession in which at one time or another he did not exercise his skill. For example, he gained an outstanding reputation as a great bridge builder. He was responsible, at first in partnership with Benjamin Baker and later in sole charge, for the widening of the Blackfriars Bridge, completed in 1909. In later years, with his partners in the firm of Mott, Hay and Anderson, he was responsible for many important bridges, the Queensferry Bridge at Chester, the Wearmouth Bridge at Sunderland, Boothferry Bridge near Goole, the Newport Bridge, the Tees Bridge at Middlesbrough, and the Tyne Bridge at Newcastle, completed in 1928. Possibly the greatest of the works with which he was associated and one which very fully absorbed his time and energies in his later life, was the Mersey Tunnel, connecting Liverpool and Birkenhead, the largest under-water tunnel in the world, completed in 1934.

During the Great War, Sir Basil rendered notable service to the Government in many directions, visiting both France and India. For his services he was made a C.B. Later, his experience was of great assistance to the Ministry of Transport in connexion with the Charing Cross Bridge scheme. He also gave advice on the Channel Tunnel project and the Severn Barrage. In 1925 he was chairman of a committee of engineers and architects which took the necessary steps for the preservation and safety of St. Paul's Cathedral.

Sir Basil was born on September 16, 1859, and was educated at Leicester, in Switzerland and at the Royal School of Mines, where he won the Murchison Medal. He became a member of the Institution of Civil Engineers in 1895 and was president of the Institution in 1924. He was elected to the Royal Society in 1927, and was also an associate of the Royal School of Mines, a fellow of the Imperial College of Science and Technology and a member of the Société des Ingenieurs Civils de France. He is succeeded in the baronetcy, conferred on him in 1930, by his eldest son, Adrian Spear Mott.

CLEMENT D. M. HINDLEY.

We regret to announce the following deaths:

Prof. L. S. Dudgeon, C.M.G., C.B.E., professor of pathology in the University of London and dean of St. Thomas's Hospital Medical School, on October 22, aged sixty-two years.

Sir Robert Mond, F.R.S., known for his researches in pure, applied and electro chemistry, and for his archæological investigations in Egypt, Palestine and elsewhere, on October 22, aged seventy-one years.

News and Views

Mr. Sidney Smith

Mr. Sidney Smith, whose appointment to the recently instituted chair of Near Eastern Archæology in the University of London (Institute of Archæology) is announced (p. 806), has been keeper of the Department of Egyptian and Assyrian antiquities in the British Museum (Bloomsbury) since 1930, when he succeeded the late Dr. H. R. Hall. Mr. Smith was educated at the City of London School and Queens' College, Cambridge, of which he was a scholar and is now an honorary fellow. He took the Classical Tripos in 1911, and proceeded to Berlin for further study in 1912. In 1914 he was appointed an assistant in the British Museum, but during the Great War he was commissioned in the Middlesex Regiment, and while on active service was mentioned in dispatches. On his return to the British Museum he continued his studies of cuneiform texts, and between 1921 and 1927 published a number of volumes of texts from Cappadocia, as well as from the Babylonian historical records. In 1921 he also published an account of the first campaign of Sennacherib. Mr. Smith was a member of the British Museum's expedition excavating at Ur in 1922–23, and in 1929–30 he served as director of antiquities in Iraq. Among much other work, Mr. Smith has contributed to the Cambridge Ancient History, and initiated and edited *Iraq*, the publication of the British School of Archæology in Iraq. Since 1923 he has been lecturer in Assyriology at King's College, London.

Prof. D. H. Robertson

Dr. D. H. Robertson has been appointed to the Sir Ernest Cassel chair of economics, with special reference to banking and currency, tenable at the London School of Economics. He will take up his duties on January 1, 1939. The Sir Ernest Cassel chair of economics, instituted in 1920, was previously occupied by Prof. T. E. Gregory, who resigned in December 1937 to take up the office of economic adviser to the Government of India. Dr. D. H. Robertson is at present reader in economics in the University of Cambridge, and has been a fellow of Trinity College since 1914. His work on industrial fluctuation and on the theory of money has given him an international reputation, recognized by the conferment on him of honorary degrees by the Universities of Amsterdam and Harvard. He has been a member of the Economic Advisory Council since 1936. He co-operated with Prof. A. L. Bowley in the Economic Survey of India, 1934. Among his published works are "A Study of Industrial Fluctuations" (1915), "Money" (1922), and "Banking Policy and the Price Level" (1926).

New Wing of Queen Mary College, London

On October 12, the Chancellor of the University of London formally opened the new west wing of Queen Mary College which has been erected upon the site of the Winter Garden of the old People's Palace. The spacious Zoology Department, fully equipped for modern requirements, occupies the top of the new wing and apart from the usual laboratories, museum, etc., possesses a special aquarium room with marine and freshwater aquaria, and two animal rooms. The removal of the Arts Departments to the lower floors of this new wing has provided room for considerable extensions of the Departments of Botany, Geology and Physics, which occupy the east wing, although the completion of the Physics Department awaits the third and final phase of the building programme. The College is now provided nearly throughout with up-to-date modern laboratories, several of which are equipped for special lines of research. In declaring the new buildings open, the Chancellor expressed the hope that funds would soon become available for completing the building programme of the College.

Rothamsted Centenary: Inaugural Meeting

While the experimental fields at Rothamsted are probably the best known and the most interesting in the world, the laboratories, farm buildings and equipment are admittedly not up to the standard of many of the Continental or American stations and do not allow of anything like so much scientific assistance to the farmer as should in these difficult times be available. The Committee of Management is taking advantage of the approaching centenary to remedy these various deficiencies and is hoping to raise a fund of £125,000, of which £80,000 would be used for buildings and equipment and £45,000 for addition to endowment so as to provide for upkeep of fabric and salary augmentations. The work will proceed in three stages. The first is the building of the new chemical and bacteriological laboratories, pot culture houses and farm buildings; this will cost about £45,000, of which, however, only £30,500 is drawn from the centenary fund, the remainder being provided by the Ministry of Agriculture. The second stage will be the building of the library at a cost of £20,000, and the third the erection of a new block to house the Imperial Soil Bureau, the Statistical Department, the administration and extension staff, a conference hall and staff common rooms: this will cost about £30,000. It is hoped to complete all three parts before the centenary occurs in 1943; hence the work is being put in hand as early as possible. This is being done partly also for the convenience of those who wish to spread their donations over a period of years. The scheme is being inaugurated at a meeting to be held on November 1 at the Royal Society's rooms, when His Royal Highness the Duke of Kent will preside, and when it will be announced that His Majesty the King, through the Duchy of Cornwall, will open the subscription list.

Tide Mills of England and Wales

In a very well illustrated lecture to the Newcomen Society on October 12 entitled "The Tide Mills of England and Wales", Mr. Rex Wailes gave a survey of all the mills of which he had been able to find any traces. In the course of two years he had visited the sites of twenty-three mills and of these ten were still worked by the tides. Starting with the county of Suffolk he described the mill at Woodbridge on the Deben Estuary, first mentioned about 1170. This mill is served by a 3,100,000 sq. ft. pond with a six-foot head. The water wheel is 20 ft. in diameter and 5 ft. 10 in. in width and it is mounted on a 22 in. square oak shaft. It drives four pairs of mill stones controlled by a single pair of governors, the only instance of its kind. There are early references to several tide mills in London, but the only ones at work are at the Three Mills Distillery, Bromley-by-Bow. Here in the House Mill are four water wheels, and in the Clock Mill, three water wheels, all about 20 ft. in diameter, driving in all eighteen pairs of stones for grinding maize, barley and other cereals for the production of spirits. The mills are semi-tidal, being worked as the water flows outward from the River Lea. Other mills still working are at Stambridge, in Essex; Beaulieu and Eling in Hampshire; Carew and Pembroke in Wales; and Emsworth in Sussex. The paper is printed and illustrated in *Engineering* for October 14.

Associated Learned Societies of Liverpool

The triennial public exhibition and soirée organized by the Associated Learned Societies of Liverpool and District to illustrate the progress in science and education since their last exhibition in 1935 was held in the City Technical College on October 22. During the course of the exhibition, Prof. E. W. Marchant gave a lecture on 'Television', H. Kendrick on "Changing India", W. H. Watts on "The

Moon , D Caradog Jones on The Changing Population of Merseyside Prof J T Craig on Veterinary Pathology , and a number of shorter talks were given in the individual rooms The Institute of Chemistry and the Society of Chemical Industry exhibited process demonstrations of artificial silk spinning, products obtainable from cotton seed, demonstrations of the action of dirt particles under the influence of electrical forces dyeing and armour plate glass , the British Association of Chemists exhibited a combined temperature and humidity recorder smoke density determination apparatus and samples from the plastics industry The Liverpool Biological Society s room included a demonstration exhibit by Prof J H Orton on his Dee fisheries work Dr R J Daniel on pearl formation and Mrs Bisbee on the ductless glands Mr Eric Hardy had arranged a special Country Side Room with Nature films photographs habitat groups of British birds and mammals bird migration (ringing) and flight (bird wing) displays illuminated natural colour lantern slides bird sanctuary devices and maps of local bird distribution The exhibition also included natural colour films an ingenious micro projector by Mr A V Wilkinson Dr Glynn Morris s geological collection and in the Engineering Society s room a trafficator for cyclists invented by Mr A Robins

Indian Adult Education

FROM the National Adult School Union we have received a copy of an appeal by its International Committee for funds to assist in the development of adult education work in India The appeal is countersigned by Mr Banning Richardson, as president of the Indian Adult Education Society and honorary general secretary All India Adult Education Conference Committee This committee has undertaken to investigate all the adult education activities which are being carried on in India and to call a conference for the early part of 1939 Annexed to the appeal is a leaflet which mentions as indicative of the character of the work now carried on by the Indian Adult Education Society the teaching of improved methods of handicrafts to undergraduates of the University of Delhi with the intention that during the vacations this instruction should be passed on to their rural relations and friends , literacy work a regular service of rural broadcasting the teaching of scholastic subjects to matriculates, who have not been able to continue their studies at a university and the giving of instruction to members in their own religion by the most capable believer in that faith available Of this last it is claimed that an improved relationship between the followers of the different religions has resulted Nothing is said about the utilization of the movement as an instrument of political propaganda, but reference is made to the fact that in the Central Provinces recently described in *The Hindu* as a thoroughly congress minded province , the Minister of Education and Vice Chancellor of the University have associated themselves with it

Royal Society of Science, Bombay

SINCE its opening in 1920, the Royal Institute of Science, Bombay, has been recognized as the foremost college in the Presidency for the training of science students The late Dr A N Meldrum the first principal and professor of organic chemistry, realized the importance of its being not merely an institution for the training of undergraduate students, but that it should also be an active centre of research He was fortunate in having the support of an enthusiastic staff and during the period of his principalship a large number of students were trained in the methods of research both in the physical and natural sciences We have now before us the triennial report of the Institute covering the years 1934–37, and we note with pleasure the continued advancement of the Institute under the energetic and enlightened leadership of its present principal Prof T S Wheeler The total number (315) of full time students is not large and of these no fewer than 94 are engaged in post graduate work which indicates the importance attached to original work

DURING the triennium dealt with in the report 159 original papers have been published of which the majority (102) come from the two departments of chemistry Whilst as is natural their contents are of varying value Prof T S Wheeler s contributions to the theory of liquids and Prof R H Dastur s work on plant metabolism have attracted widespread attention In its recent visit to Bombay, the British science delegation had the opportunity all too short of visiting the Institute and of seeing something of the work which is being so actively pursued Contrary to the experience elsewhere in India no difficulty has been encountered in finding employment for students, of whom only 0 6 per cent were unemployed, whilst 21 8 per cent had obtained industrial posts It is very much to be hoped that no considerations of economy will be allowed to weaken the activities of the Institute since to the students now under training there the industries of the Bombay Presidency must largely look for their future advancement

Acquisitions at the British Museum (Natural History)

THROUGH the kindness of the Rev I H Wilson of Inkongo in the Sankuru district of the Congo the Museum has received a female specimen of the recently discovered peacock like bird, *Afropavo congensis* This bird was first discovered by Dr James P Chapin, of the American Museum of Natural History, New York, in 1936, who found two mounted examples in the Ethnological Department of the Tervueren Museum Brussels, where they had been overlooked Later the authorities of that Museum received further specimens from the Congo Dr Chapin visited the area and his native hunters brought in two more, while he himself had a fleeting view of one bird in the forest The interesting feature of this bird is that in some of its characters it resembles the peacock a bird which is confined to Asia Specimens of diamondiferous gravels and concentrates have been received from the Geological Survey of the Gold Coast Colony, and Prof Takeo Watanabé has presented a specimen of the new mineral kotoite—a magnesium borate occurring as a rock forming mineral in limestone in Korea A magnificent group of yellow and green zoned crystals of fluor from a mine in Weardale has been purchased and the opportunity has been taken to re arrange the exhibit of fluor in the pavilion of the Mineral Gallery Mr P M Game, a member of the staff of the Department of Minerals, who recently returned from an expedition to West Greenland under the leadership of Dr H I Drever, has brought back a collection of about three hundred specimens of rocks and minerals from Ubekendt Island, Umanak Fjord, a region in which no previous geological work had been done

The Department of Botany has received two collections of plants from expeditions made by students of Imperial College The first is from Jan Mayen, and contains 427 numbers mostly collected by Mr R S Russell The collection is a very valuable one as each number usually contains ample material The Department now has practically a complete representation of the species recorded from the island, which is of special interest in view of its position in mid ocean between the Old and the New Worlds The second is from Finmark, and consists of 350 numbers of dried plants and some fungi in spirit, collected for the most part by Mr H D Jordan The specimens are mainly from the base camp area at the head of Lakse Fjord and in the still incompletely mapped hinterland, which was crossed up to a little beyond River Tana The Oxford University Expedition to the Cayman Islands obtained 678 numbers of flowering plants and 614 numbers of cryptogams for the Department, collected by Mr W Kings The specimens are well preserved, and, as the islands are little known botanically, the collection should prove an interesting one Mr C A Lister accompanied the Public Schools Exploring Society s Expedition to Newfoundland and collected 173 phanerogams and 34 cryptogams These have been presented to the Department and supplement the previous collections made in these expeditions The specimens are very well preserved The British herbarium of the late Mr F J Hanbury, which was bequeathed to the Museum, contains more than 20,000 sheets As Mr Hanbury always aimed at a large series of specimens and as he was responsible for a considerable number of records to the Supplements to Topographical Botany", the material is especially useful The chief value of the herbarium is probably in the fine collection of *Hieracium*, for Mr Hanbury began the publication of a monograph of the genus and compiled the account in the ninth edition of Babington's 'Manual", it contains the *Hieracia* of James Backhouse, the first monographer of the genus in Britain The Department has also acquired Lieut -Colonel A H Wolly Dod's collections of *Rosa* Colonel Wolly-Dod is the recognized British authority on the genus, and many of the specimens have been examined by other specialists

Philosophy and History

In the annual philosophical lecture on 'Some Problems of the Philosophy of History' delivered under the Henriette Hertz Trust before the British Academy on March 16 (London Oxford University Press 1*s* 6*d* net) Prof G C Field urged that all serious philosophical thinking must be based on an examination of the assumptions actually made in the other established forms of thinking If the philosopher wishes to proceed eventually to a general theory of knowledge or reality he must take this as his foundation and evidence Prof Field suggested that among the established forms of thinking history holds an important place and deserves serious consideration in view of the tendency to suggest that the assumptions of physical science must be the assumptions of all valid thinking History forms a coherent body of thought in which mutual understanding and cooperation between large numbers of people are possible and has independent claims to consideration as an essential part of the evidence on which our final theories must be based Prof Field distinguishes three main elements in the general structure of historical thinking imaginative reconstruction of past events or situations, the belief that this imaginative reconstruction is correct, corresponding to, or being like in some degree what really happened, and the evidence on which our conclusions are based Discussing the dependence of our historical beliefs on narrative, he referred to the question of selection in imaginative reconstruction and its bearing on the understanding rather than the mere recording of what happened

University of Manchester and its Alumni

The second number of the *Journal* which the University of Manchester has established as a means of keeping its members in touch with its activities and plans maintains the high standard of its predecessor A message and appeal to its graduates by the Vice Chancellor is followed by a number of articles of more than local or passing interest The School of History, the Physics Department, the University Settlement and Halls of Residence are discussed by Profs E F Jacob and W L Bragg, Mr Pilkington Turner and the wardens of two of the Halls Mr John Coatman North Regional director of the B B C, writing on The Significance of a Lancashire University in the Community argues ingeniously that the circumstances of to day call for a vision of international economic and political relations as clear and fruitful as that which gave Lancashire its greatness a century ago and that, to meet this need, its universities, the county s great intellectual power houses', should devote themselves increasingly to the philosophical study of the principles of human association, examination of the economic and political forces at work inside and between nations, and clear sighted, intelligible analysis of the forces which mould public opinion determine national policies, and thus in the end control international relations Furthermore, he urges that in the systems of education which come within their influence they should give an increasing bias to such studies and especially the study of the British Commonwealth of Nations, as an example of a new kind of political association between free and independent peoples, based on principles which are universally and permanently valid.

Beneficial Employment and Vocational Guidance

LOCAL education authorities will, next year, be called upon to consider applications for exemption from compulsory school attendance of children between fourteen and fifteen years of age and to determine in each case whether the employment proposed will be 'beneficial' to the child. The Board of Education has suggested to local authorities, among other measures for qualifying themselves for determining these difficult questions, the requirement of a school report indicating the child's good, average and weak subjects and information regarding manual or domestic training received, and a medical report expressing the doctor's opinion as to the types of occupation unsuitable for the child—hence a widespread stimulation of interest in the principles and practice of vocational guidance, a subject in which there has been a large amount of research in America. The United States Office of Education, with the assistance of the National Occupational Conference, has prepared bibliographies of current literature in this field and recently published a "Guidance Bibliography" (Bulletin No. 37. Washington, D.C.: Supt. of Documents. 10 cents), an annotated list of 442 books, pamphlets and periodical references classified under the headings: elementary schools, secondary schools, colleges, adult and out-of-school youth, and techniques and procedures. Information as to careers is published monthly by the National Occupational Conference in an Occupational Index.

The English Sprat Fishery

THE Ministry of Agriculture and Fisheries paper by Mr. J. Armitage Robertson on "The Sprat and the Sprat Fishery of England" (Fisheries Investigations, Series 2, 16, No. 2) deals with the economic importance of the sprat, the location of the fishery, behaviour and geographical distribution, life history, age, sex ratio and food. Even the health of the sprat is treated in a section devoted to 'parasites and disease', from which the sprat seems tolerably immune. The fishery is a localized inshore winter one, confined to the south coast and East Anglian seaboard, and is prosecuted in a variety of ways: by drift nets, stow nets, trawls and seine nets. The possibility that the shoals are 'driven' shoreward by the incursion during the winter months into the Southern Bight of the North Sea of water of a higher salinity (greater than 35 per mille) than that to which they are accustomed is discussed, but Mr. Robertson is insufficiently convinced by the available data on this point and considers "that these hydrographical conditions and the circumstances of the fishery do not bear the relation of cause and effect, but are merely due to some general and common cause such as 'Winter Conditions'." In spite of a Norwegian authority's statement that English sprats are "tough, coarse and unpalatable", Mr. Robertson finds nothing to support this, and recommends as beneficial both to the fishery and to the country the development of the already existing small sprat canning industry in Great Britain. English prices vary between 3s. and 16s. per cwt., whereas the average cost of imported canned brisling, mostly from Norway, is £6 13s. per cwt., so that the industry should have an ample working margin.

Radio Interference by Electro-Medical Apparatus

IN a recent article in NATURE (May 21, p. 941), attention was directed to the widespread interference caused to radio reception by various classes of electrical apparatus. One of the sources of such interference and also one of the most difficult to mitigate is a certain type of electro-medical apparatus used for diathermy treatment. With the view of securing an amelioration of conditions in this field, the Postmaster General has asked the Minister of Health to direct the attention of local authorities to this matter. Accordingly a circular letter has been issued by the Ministry of Health to all local councils including welfare and local education authorities (Circular 1695). With this circular was enclosed a memorandum prepared by the Radio Branch of the Post Office on the prevention of interference with radio reception from certain types of electro-medical apparatus. This memorandum has been reprinted from *The Hospital*, the official organ of the British Hospitals Association. It is to be noted that modern valve-rectified X-ray apparatus is not likely to cause interference, and the memorandum is primarily concerned with certain diathermy installations working on medium waves, short waves, and ultra-short waves which can only be prevented from causing interference by the addition of an electrical screen or Faraday cage capable of enclosing not only the apparatus but also the patient and the operator. Since no other effective method of prevention has yet been discovered, it seems desirable that for new hospital buildings or extensions of existing hospitals or other new buildings in which these forms of apparatus are likely to be used, the inclusion of screened rooms should be considered. Attention is directed to the fact that the Radio Branch of the Post Office is prepared to advise on any problem arising and also on the prevention of interference from existing plant.

The Cheshunt Research Station

THE annual report for 1937 of the Experimental and Research Station at Turner's Hill, Cheshunt, Herts, announces a new auxiliary venture. It was recognized that the control of virus diseases of cucumbers and tomatoes could only be accomplished by the use of seed from disease-free plants. A Seed Growers' Association is therefore to be formed to carry on this commercial side of the Station's activity. A capital of £3,000 has been subscribed, and will enable the venture to start. Many experimental trials which have been prosecuted in previous years are continued to give conclusive results. Such are the effect of restricted rooting upon early fruiting of the tomato, the use of electric light to hasten growth of cucumber seedlings, the use of soil heating for several crops, and the use of a surface rooting medium for tomatoes Entomological investigations have included studies of rose thrips and onion thrips and the use of a species of *Scolothrips* as a predatory control of red spider mite Extensive mycological researches include the record for the first time in Great Britain, of a leaf spot of marguerite caused by the fungus *Ramularia bellunensis* Physiological estimations of tomato seedlings have also been accomplished, and more general problems of soil nutrition have been studied

Lighting and Speed of Seeing

A RECENT article (*Brit Eng Export J* , September) describes practical advances that have recently taken place in lighting An interesting experiment is described which shows a relation between illumination and the speed of vision The apparatus used was a heavy pendulum on which a test object was exposed to view when swinging between two screens The speed of movement of the object was directly proportional to its distance from the pivot At high illuminations the test object could be seen when it was placed at the lowest point of the pendulum At intensities not exceeding two foot candles, it was only visible when it was placed at a distance not exceeding a quarter of the way down, when its speed is only a quarter of what it is at the lowest point After an increase to five foot candles the speed of seeing was increased by about 60 per cent

Model Chinese Junks

A COLLECTION of large scale models of Chinese junks, which is said to be unique has been presented to the nation by Sir Frederick Maze, inspector general of Chinese customs, for exhibition in the Science Museum, South Kensington The models, ten in number, were built in Hong Kong or Shanghai by Chinese craftsmen, and are accurate replicas of these sailing craft in every detail, down to the shrines and household gods They include examples with the magical eye on the prow These boats, which are now giving place to steam in Chinese waters, and have also suffered many casualties during the present warfare, are of two main types, a northern and a southern Except for details of rigging, they have not altered in principle over a prolonged period —at least a thousand years and some authorities would hold for perhaps twice as long before that Of these types, one has bluff bows and a flat bottom adapted for sailing in shallow waters The other type has a sharp bow, with sheer lines and a deeper draught Details of construction and rig in use among Chinese sailors at an early date are shewn in these models, which did not appear in Western ships until a very much later period Such, for example, are the water tight compartment, the battened sail used in yacht racing, lee boards of the keel and rudder types, and multiple sheets for independent handling of the upper and lower parts of the sails

Sternberg Astronomical Institute

ACCORDING to Russia Today' Press Service, buildings for the Sternberg Astronomical Institute of Moscow will be commenced early next year in the vicinity of Butovo Station, one of the highest points on the outskirts of Moscow The observatory, laboratory mechanical workshops and blocks of flats to house the staff of the Institute will occupy a site of 14½ acres The main part of the Institute's building will contain accommodation for research workers, lecture rooms a library for 100 000 volumes and a storehouse for the 60 000 photographic negatives taken by the Observatory and by the Southern Astronomical Station in Tajikistan Underground in the same block will be situated the time service with its astronomical clocks and a gravimetric laboratory A tower to be erected over the main body of the building is to be used for solar work The removal of the Institute from Moscow is necessitated by the traffic and the reflection of the city s electric lights in the sky, which interfere with astronomical observations

Centenary of the Greek Archæological Society

CELEBRATION of the centenary of the Greek Archæological Society began at Athens on October 23 The proceedings were opened in the Parthenon by the King of Greece president of the Society, who delivered an address of welcome to the delegates and representatives of Greek and foreign universities and learned societies Great Britain was represented by Mr William Miller, of the British Academy, Mr R D Barnett of the Society for Hellenic Studies and Mr Gerald Mackworth Young who was present on behalf of the Society of Antiquaries of London and the British School of Archaeology at Athens The programme of the celebration, it is reported in *The Times* of October 24, includes excursions to Delphi Eleusis and Epidaurus, the conferring of academic honours on distinguished archæologists, the laying of wreaths on the Cenotaph and the statue of the late King Constantine, a former president of the Society, the performance of the *Electra* of Sophocles and *King Lear* an official banquet given by the Government, and a number of receptions

The Night Sky in November

THE moon is full on November 7 at 22 4^{h} and new on November 22 at 0 1^{h} U T On November 7, there will occur a total eclipse of the moon under favourable conditions—given fine weather—for observation in Great Britain Contact of the umbra with the moon s limb at position angle 94° from the north point, measured towards the east, occurs at 20^{h} 41^{m} , total eclipse begins at 21^{h} 45^{m} and ends at 23^{h} 8^{m} , the moon leaves the umbra at 0^{h} 12^{m} November 8 the position angle of the last contact being 243° Lunar conjunctions with the planets occur on November 1^{d} 19^{h} (Jupiter) 5^{d} 18^{h} (Saturn) 18^{d} 18^{h} (Mars) 23^{d} 21^{h} (Mercury) and 29^{d} 8^{h} (Jupiter) There is a conjunction of Mercury and Venus on November 8, but both planets set very shortly after the sun As the sky darkens, Jupiter is seen as a very bright object rather low near the meridian Saturn souths shortly after 21^h in mid November Mars is a morning star rising at $3\frac{1}{2}^h$, on November 28, the planet passes 3° north of Spica Uranus, in the constellation Aries, is in opposition on November 8, its distance from the earth being nearly 1,736 millions of miles The Leonid meteors should be looked for on November 15–16 the χ Taurids on November 14–16 and the Andromedids from November 17 to 23 The light change of the variable star, Algol, should be seen about one and a half hours before and after the following times of primary minima November 9^d 6 0^h 12^d 2 8^h 14^d 23 6^h 17^d 20 4^h 20^d 17 2^h and 29^d 07 7^h

Announcements

AT the annual statutory meeting of the Royal Society of Edinburgh held on October 24, the following Council was elected *President* Sir D Arcy Thompson *Vice Presidents* Prof F A E Crew Lieut Col A G M Kendrick , Principal J C Smail Prof J Walton , Dr James Watt , Prof F T Whittaker *General Secretary* Prof James P Kendall , *Secretaries to Ordinary Meetings* Dr A C Aitken and Dr C H O Donoghue , *Treasurer* Dr E M Wedderburn , *Curator of Library and Museum* Dr Leonard Dobbin , *Councillors* Dr J E Mackenzie , Prof Sydney Smith Prof R Stockman , Prof Lancelot Hogben , Prof James Ritchie , Dr G W Tyrrell Prof C T R Wilson , Prof R C Garry , Prof R J D Graham , Prof D Murray Lyon , Dr J E Richey and the Hon Lord Robertson

JUNIOR research fellowships in tropical medicine have recently been awarded by the Medical Research Council to the following Dr S G Cowper, A J Haddow, and W H R Lumsden The fellowships are tenable for three years, during the first two of which the holders will undergo training in Great Britain in tropical medicine and in the use of research methods

AN inscribed stone has been fixed at No 32, Soho Square, W 1, recording the fact that Sir Joseph Banks, president of the Royal Society, and Robert Brown and David Don, botanists, lived at the house which formerly stood on the site, and that the Linnean Society met there from 1821 until 1857 (see also NATURE, 139, 280 , 1937)

AN earthquake of moderately large proportions was recorded on seismographs in England on October 19d 4h 22m 54s G C T Mr J J Shaw's record was uncertain owing to interference by the wind The Kew record indicates an epicentral distance of approximately 53 3°, but the azimuth is uncertain No damage has been reported

ON October 22, Lieut Colonel Mario Pezzi regained for Italy the height record for aeroplanes by flying to a height of 17,074 metres The previous record, held by England, was that of 16,440 metres, attained by the late Squadron Leader M J Adam The Italian flight was made in a Caproni machine fitted with a specially constructed Piaggio engine, details of which are not disclosed

PROF F F NORD, of the University of Berlin, known for his contributions to the chemistry of enzymes, heterogeneous catalysis and cryolysis of colloids, has accepted the chair of organic chemistry in Fordham University, New York, N Y Prof Nord will continue to be editor of *Ergebnisse der Enzymforschung*

THE following have recently been elected members of the Imperial Leopold Caroline German Academy at Halle Dr Philipp Stohr, professor of anatomy at Bonn Dr Richard Siebeck, professor of internal medicine at Berlin , Dr Paul Wels professor of pharmacology at Greifswald , Dr Georg Stetter, professor of physics at Vienna Dr Abraham Esau, professor of technical physics at Jena , Dr Fritz Kohlrausch, professor of physics at Graz , and Prof Walter Schoeller of Berlin

AN industrial fellowship has been established by the Elgin National Watch Company, Elgin, Illinois, at the Mellon Institute, Pittsburgh, Pa The research programme will cover broadly the chemical aspects of technical problems in the watch industry One of the first subjects of investigation will be watch lubrication Dr George E Barker, of the Massachusetts Institute of Technology, has been appointed to the fellowship Before joining the Institute s research staff, Dr Barker spent several years in the synthetic organic chemical industry

THE foundation stone of an institute of hygiene, social medicine and industrial pathology has recently been laid at Brussels

ACCORDING to the National Safety Council of the United States, in the first four months of 1938 there were 2,060 fewer traffic deaths than in the corresponding months of 1937, or a reduction of 19 per cent

OWING to the recent crisis, the second International Congress of Radio Æsthesia which was to have been held in Paris on October 17–19 has been postponed to November 7–9 Further information can be obtained from the Secretariat, 9 rue Etex Paris 18

THE third Italian Congress of Medicine and Sport will be held at Genoa on November 12–14, when discussions will be held on the reduction of professional capacity from internal lesions following sport and reduction of working capacity from injury to the locomotor system

THE Congress of Rheumatism organized by the French League against Rheumatism, which was to have been held on October 8, has been postponed until December 3 Further information can be obtained from the Secrétariat de la Ligne française Centre le Rhumatisme, 23 rue Cherche Midi, Paris, 6e

Letters to the Editor

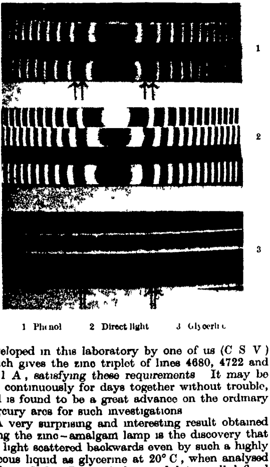
The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return or to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK S LETTERS APPEAR ON P 799

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Debye Heat Waves in Highly Viscous Liquids

FOR the spectroscopic study of the light scattered in solids and fluids using interferometers of high resolving power, it is very important to be able to work with a light source giving sharp and intense spectral lines without accompanying hyperfine structure components or continuous spectrum A zinc-mercury amalgam lamp in Pyrex glass has been developed in this laboratory by one of us (C S V) which gives the zinc triplet of lines 4680, 4722 and 4811 A, satisfying these requirements It may be run continuously for days together without trouble, and is found to be a great advance on the ordinary mercury arcs for such investigations



1 Phenol 2 Direct light 3 Glycerine

A very surprising and interesting result obtained using the zinc-amalgam lamp is the discovery that the light scattered backwards even by such a highly viscous liquid as glycerine at 20° C, when analysed with a Fabry Perot étalon, exhibits well-defined Brillouin components on either side of the incident lines, along with a continuous background A similar result is also shown by liquid phenol at room temperature These facts are illustrated in the accompanying reproductions (1 and 3), 2 being the corresponding pattern for the zinc triplet in the incident light It will be noticed that the undisplaced lines in the scattered light are very intense relatively to the accompanying Brillouin components The failure to observe these latter components with glycerine and phenol at room temperatures in earlier investigations[1] with the mercury arc is readily understood, with the mercury radiations the hyperfine structure of the undisplaced central line would completely overwhelm the much feebler displaced components in the scattered light

The viscosity of glycerine at 20° C is 8 3 poises and if this viscosity were effective in the propagation of compressional waves having a wave length comparable with that of the incident light these waves would be so highly damped that they could have no physical existence and the corresponding Brillouin components would therefore be unobservable The fact that the latter are actually to be seen and indeed are quite sharply defined seems to indicate that the usual hydrodynamic viscosity has little influence on the propagation of thermal sound waves of very high frequencies

Mathematics of Air Raid Protection

IN view of the discussion which is occurring on this subject, it seems desirable to have some quantitative measure of the degree of protection afforded by a given shelter In order to limit the problem we may consider only risks of death, and further confine ourselves to high explosive bombs Incendiaries have proved a negligible danger to life in Spain and gas is also negligible except for babies and those whose respirators do not fit

Consider a given type of bomb, say a 250 kilo bomb, which is commonly used on central areas of Spanish cities and a man in a given situation, whether in the street or in a shelter Let n be the expected number of bombs falling in his neighbourhood (say, 1 square kilometre) during a war the distribution of bombs over this area being supposed even since aim is poor when cities are bombed Let p be the probability that a single bomb falling at the point (x,y) in this area will kill him Then the probability that he will be killed in the course of the war is $P = \frac{n}{A}\int p dx dy$ integration being taken over the whole neighbourhood of area A

The values of n and p will, of course, be different for each type of bomb, and the different expressions so obtained must be summed Further, the man will be in different places during the war, and thus another summation is necessary Finally, P must be summed for the whole nation

The policy of evacuation is intended to reduce the value of n, even though it may increase that of p, as when a child is evacuated from a fairly solid house into a flimsy hut The policy of dispersal within a dangerous area does not, of course, reduce either n or p It merely ensures that no single bomb will kill a large number of people, while increasing the probability that any given bomb will kill at least one It is likely to save a few lives by equalizing the numbers of wounded to be treated in different hospitals, and the psychological effect of having 20 killed in each of 10 areas may perhaps be less than that of 200 killed in one area But as it may actually increase the mean value of p by encouraging people to stay in a number of flimsy buildings rather than one strong one, it is at least as likely to increase the total casualties as to diminish them The argument that a number of people must not be concentrated in one place in order that a single bomb should not kill hundreds is clearly fallacious when applied to a war in which the total casualties will be large It is, however, true that a small group of key men each of whom can replace another should not be grouped together

The effect of shelters is to diminish the mean value of p, which approaches zero in a deep tunnel, and is maximal in an open space with a hard surface which bombs will not readily penetrate The component of p due to splinters is large in the open, but negligible in any shelter worthy of consideration, though not so in the average brick house In general the construction of shelters should have two aims, namely, to diminish p in the immediate neighbourhood where a bomb falls, and to diminish the area over which p has a value large enough to be taken into consideration

With a good many types of shelter, p approaches unity within a certain area, and zero outside it Thus in a trench with protection from falling splinters p is nearly unity if a bomb falls in the trench, and nearly zero if it does not In these cases it is clear that P depends mainly on the area of a straight section of trench, and is about seven times as great in a trench 70 feet long by 6 feet wide as in one 16 feet long by 4 feet wide This fact has largely been neglected in the construction of trenches in our parks

Again, a shelter with a roof of concrete one foot thick will give $p = 0$ for very light bombs, a fractional average value of p for medium bombs which will not penetrate the roof before explosion, but will knock down a portion of it on explosion, and $p = 1$, or nearly so, for heavy bombs with delayed action, which will penetrate the roof and burst in the shelter It follows that the area of such shelters should be minimized, or they should be divided up by very stout walls, for example, reinforced concrete walls at least a foot thick This is not in order to diminish the number who may be killed by a single bomb, but to diminish the area within which a bomb must fall so as to kill a given individual

It would seem that, in the design of many shelters, too much stress has been placed on vertical protection, that is to say, protection from bombs falling immediately on the individual's protection, and not enough on horizontal protection, that is to say, protection from bombs falling at some distance from them

I suggest that, for each type of shelter, it should be possible to arrive at a rough value of P/n per square kilometre, and that such values would be of great utility in the design of shelters, though I regard any shelters for which this value is not very close to zero as inadequate Thus, to take definite examples, the value of P/n for a straight covered trench 5 metres by 1 metre would begin at about 9×10^{-4} for 20 kgm bombs, supposing that such a bomb would kill everyone in the trench if it fell within 30 cm of it It would rise to about 4×10^{-4} for a bomb making a crater of 10 metres in diameter The same value, for a square shelter of 100 square metres with a concrete roof 30 cm thick but thin walls, would rise from nearly zero for a 20 kgm bomb to about 8×10^{-4} for a heavy bomb making a 10 m crater These figures could, of course, be improved, and are only presented as approximations But they suggest that in an area where heavy bombs are likely to be used the trench is to be preferred On the other hand, were the concrete shelter divided into a number of cells by stout walls, it would be safer than the trench

Only by such quantitative treatment can we expect to avoid mistakes in policy and design of shelters such as have occurred and are still occurring It is, however, to be hoped that these calculations may be rendered needless by the provision of completely bomb-proof shelters such as exist in some Spanish towns

The Arms Race of 1909–13

THE interaction of fear with cost and with grievances was represented in a letter in NATURE (Dec 25, 1935) by the equations

$$dx/dt = ky - \alpha x + g\ , \quad dy/dt = lx - \beta y + h, \qquad (1), (2)$$

in which t is time and α, β, k, l are positive constants, and g and h are positive or negative constant grievances In that publication, x was described as the variable preparedness for war of the first group of nations, y that of the second But on further consideration, it appears that the description of x given in 1935 needs to be modified by taking into account the co-operation between the groups of nations which goes on as trade, travel and correspondence concurrently with their mutual threatenings The improved description of x is in general terms

$$x = \text{threats minus co-operation}$$

In the hope of reaching quantitative measures, let us try

$$x = U - U_0\ , \quad y = V - V_0, \qquad (3), (4)$$

in which U is the annual defence budget for the first group of nations, V that for the second group, and U_0, V_0 are measures of co-operation U, V, U_0, V_0 are all here expressed in million pounds sterling As a tentative assumption, let U_0, V_0 be regarded as constants during the arms-race (5)

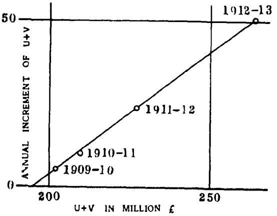
In 1909 France was allied with Russia, Germany with Austria-Hungary These two pairs of nations were very roughly equal, so that we may simplify (1) and (2) by putting $k = l$, $\alpha = \beta$ Then, by addition, it follows that

$$\frac{d(x+y)}{dt} = (k-\alpha)(x+y) + g+h\ ,$$

and by substitution of (3), (4), (5)

$$\frac{d(U+V)}{dt} = (k-\alpha)(U+V) + \{g+h - (k-\alpha)(U_0+V_0)\}.$$

This implies that when $d(U+V)/dt$ is plotted against $U+V$, we should expect a straight line of slope $k-\alpha$ The statistics for Austria Hungary have been taken from the "Statesman's Year Book', those for the other countries from a pamphlet by Per Jacobsson[1] The accompanying diagram shows that the four points lie close to a straight line of slope $k-\alpha = 0\ 73$ year^{-1} Furthermore, by a short extrapolation, the line cuts the axis of zero $d(U+V)/dt$ at $U+V = 194$ This 194 million sterling is the amount of defence expenditure, by the four nations concerned, that would just have been mutually forgiven in view of the amount of goodwill then existing



It is, to say the least, a remarkable coincidence that the trade between these opposing pairs of nations was on the average 206 millions sterling, close to 194

A much fuller discussion is due to appear under the title "Generalised Foreign Politics In particular, the assumption that U_0, V_0 were constant cannot be expected to remain valid for long periods of time Also the budgets are variously stated

Resonance Absorption of Slow Neutrons

We have made measurements of the position of the resonance levels of some heavy elements for slow neutrons The method is a development of that of Preiswerk and v Halban[1], and depends essentially on finding how much paraffin must be traversed by neutrons in order to have their energy reduced from that of the resonance level of the element under investigation to that corresponding to known periods of silver or rhodium In this way definite evidence has been obtained for resonance levels in cobalt, bismuth, lead, thorium, uranium, besides the known ones of silver and gold The most interesting result is that two levels can be detected in bismuth, the first at about 1 volt, the second at about 11 volts As bismuth is a pure element, both levels represent high excited states of radium E Preliminary experiments with thorium and uranium give similar results, showing for thorium two levels, in the neighbourhood of 2 and 18 volts respectively, and for uranium levels about 5 and 30 volts With cobalt we find a level at about 1 volt and nothing else of any intensity up to 40 volts While it will require a careful study of the experimental conditions before these resonance energies can be fixed with certainty, we think these results give a trustworthy picture of the separation of energy levels in heavy elements Such values are quite compatible with current theoretical ideas as is also the suggestion of greater separation for the lighter element cobalt and an increase in the separation as the first level goes to higher energies

It seems likely that the interesting anomalous absorption of slow neutrons in boron recently reported by Michiels[2] can be explained by the existence of two resonance levels in iodine He finds, using iodine as a detector that the absorption coefficient in boron is greatly altered if iodine is used as an initial filter instead of boron If we assume to a first approximation that energy losses are unimportant then the use of a sharply resonating detector effectively reduces the experiment to the investigation of the absorption of a heterogeneous beam consisting of as many homogeneous components as the detector has resonance levels Suppose I_1 and I_2 are the initial intensities of the low and high energy components, τ_1 τ_2 and μ_1 μ_2 their absorption coefficients in iodine and boron respectively, and d_1 and d_2 the thicknesses of the iodine and boron filters, then the smaller boron absorption coefficient with iodine filtering means that $(\tau_1-\tau_2)d_1$ is greater than $(\mu_1-\mu_2)d_2$ The approximate constancy of the boron absorption coefficient with increasing boron filtering and on the other hand its decrease with increasing iodine filtering means that $\tau_2 I_2/\tau_1 I_1$ is much less than $e^{(\mu_1\ \mu_2)d_2}$ but comparable with $e^{(\tau_1\ \tau_2)d}$ Such relations are quite plausible but a closer analysis is not justified unless great care is taken to allow for the scattering The pronounced effect of different arrangements is shown by the divergence between Michiels' results for iodine filtering and those of Ruben and Libby[3] On the evidence available, it appears as if iodine has two levels, one in the neighbourhood of 40 volts and the other of several hundreds of volts

The significance of the change in activity when two filters of boron and iodine were used simultaneously first in one order and then reversed, can only be appreciated when all scattering effects and losses of energy in any hydrogenous material present are carefully taken into account but it must be remembered that similar effects were found in the early days in the experiments on the absorption of heterogeneous γ ray beams

Viscosity of Light Hydrogen Gas and Deuterium between 293° K and 14° K.

In connexion wit' previous systematic investigations[1] on the viscosity of gases at low temperatures, we have studied hydrogen and deuterium gas As is well known, such investigation is interesting in connexion with the theoretical calculations made respectively by Uehling[2] and Massey and Mohr[3]

As in our previous investigations, we used the oscillating disk method, with very small plate distances Considering the results obtained for light hydrogen (T = 293° K , $\eta \times 10^7$ = 882 7 , 89 4°, 387 1 , 77 3°, 345 8 , 20 3°, 108 8 , 18 5°, 102 4 , 16 7°, 90 3 , 15 1° 80 8 , 14 1°, 74 5), it will be observed that our results are in good agreement with the results obtained by Kamerlingh Onnes, Dorsman and Weber[4] and by Sutherland and Maass[5] The values published recently by Keesom and Macwood[6] for the viscosity of light hydrogen at liquid hydrogen temperatures are about 20 per cent higher On the other hand, the values obtained by Vogel[7] and Gunther[8] are about 10 per cent smaller than our values and those of Kamerlingh Onnes Dorsman and Weber

From our measurements on the two kinds of hydrogen we determined the ratio η_{D_2}/η_{H_2} as a function of temperature So we obtained at T – 293° K η_{D_2}/η_{H_2} – 1 39 , 90° 1 34 , 80°, 1 35 75°, 1 35 , 20° 1 24 , 17°, 1 24 , 15°, 1 24 , 14°, 1 25

Thus at room temperature the ratio η_{D_2}/η_{H_2} is in good agreement with the ratio of the square root of the molecular masses of the two molecules At lower temperatures there is a regular decrease in this ratio This decrease cannot be attributed to the presence of a small per cent of H_2 in the D_2 gas

More details on these measurements will be published shortly

Absorption of Gases by Tantalum

Hydrogen A number of workers have measured the absorption of hydrogen by tantalum , thus Pirani[1] found a large absorption at yellow heat, Moers[2] measured the quantity taken up at higher temperatures, while Fetkenheuer[3] found a maximum in the absorption at about 600° C On the other hand, Sieverts showed a curve[4] in which the quantity taken up was greater at 20° C than at higher temperatures The clean up at low pressures does not appear to have been discussed in detail, although Balke stated[5] that below 1 micron the clean up was very small

We have studied the clean up of hydrogen at pressures from 1 micron to 30 microns on a tantalum strip of area 2 cm ^{2} and mass 50 mgm If the strip was degassed at temperatures below 1,500° C , surface oxide remained present In this state the clean up was as found by Fetkenheuer[3] It was negligible below 400° C , reached a maximum at 600° C , and decreased again, becoming very small at 1,000° C The absorption at 600° with a pressure of 1 micron was only about ½ cu mm measured at S T P If, however, the strip was run in a very high vacuum for a long period at 1,900° C or for a short period at 2,200° C , further gas was evolved, the strip became cleaner in appearance, and the clean up of hydrogen was profoundly modified The maximum absorption now occurred at 20° C as found by Sieverts[4], while there was a continuous decrease in absorption from 100° C to 1,000° C as in Sieverts curve The clean up was very rapid, the total quantity cleaned up at 1 micron pressure and 20° C being about 20 cu mm measured at S T P The clean up was proportional to $\sqrt{P}$ from 1 micron to 30 microns , if proportionality continued to atmospheric pressure, the absorption at that pressure would be 17 5 c c If this is expressed in c c of hydrogen per gm of tantalum, the figure is 350 c c /gm , which is about seven times Sieverts figure It is probable, however, that saturation occurs below atmospheric pressure All the gas cleaned up at 20° C was liberated again at 950–1,000° C , and was partially liberated at lower temperatures

Above 1,200° C absorption appeared to increase again although measurement was difficult on account of the rapid formation of atomic hydrogen at the higher temperatures There appeared to be an increase to about 1,700° C and a decrease above absorption becoming negligible above 1,900° C The maximum absorption was however, much less than that at 20° C

Exposure of the strip at room temperature to small pressures of oxygen restored the first type of behaviour Exposure at 600° to oxygen led to this type of behaviour in a more marked degree, with a very small clean up of hydrogen at 600° Prolonged running at 2,200° C was then necessary to restore the second type of behaviour

Nitrogen Variable results have also been obtained on absorption of nitrogen by tantalum[6 7] We have found that after running at 2,100° C in high vacuum, clean up of nitrogen at 1 micron appears at 700° C , and is very rapid at 1,000° C , it remains constant from 1 000° to 1,500° C , and decreases at higher temperatures All the gas cleaned up at 1,000° is liberated at 2,100° C and is partially liberated above 1,900° C The absorption at 1,000° C was not determined exactly, but was certainly greater than 25 c mm measured at S T P when the pressure was 3 microns

A strip in the oxidized condition after degassing at 1 500° only showed no absorption of nitrogen below 850° C , while absorption only became rapid above 1,200° This result is that obtained by Moissan[7] Thus in the case of both hydrogen and nitrogen, the earlier variable results have been due to contamination of the tantalum surface by oxide Similar degassing treatments were found necessary in work on the thermionic and photo electric properties[8 9]

Variation in the Longitudinal Incremental Permeability due to a Superimposed Circular Field

During the course of an investigation of the variation of the longitudinal incremental permeability by a superimposed circular magnetic field some rather interesting results were obtained with certain iron nickel alloys The ferromagnetic materials under investigation were of wire form and served as the core of a long slender solenoid Direct current was passed through the core to produce the circular field, and the longitudinal permeability was calculated from inductance measurements on the solenoid

Using well annealed alloys, it was found that rather large increases in the longitudinal incremental permeability could be obtained as a function of a relatively small superimposed circular field while upon twisting the conducting core a gradual change from an increase to a decrease in the incremental longitudinal permeability as a function of a superimposed circular field was obtained

These effects are shown in Fig 1 where curve (*a*) gives the variation of the inductance of the solenoid as a function of the direct current through the conducting core of an unstrained sample Curve (*b*) is that obtained after the core has been twisted through 120° Here the inductance of the solenoid without any core is 1 3 millihenries In all measurements the effect of the earth s field was reduced to a minimum and the samples were completely demagnetized before each run

Fig 2 shows the variation in longitudinal incremental permeability of the core as a function of the degree of twist when a current of 0 5 amp passes through the core Variations in permeability thus obtained on the samples were much greater than those obtained by twisting when no current passes through the core

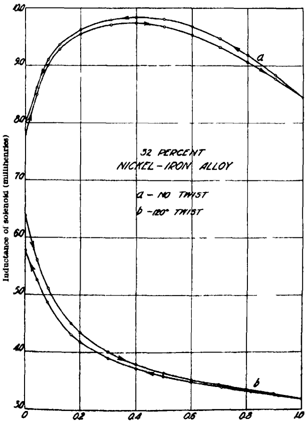

Fig 1

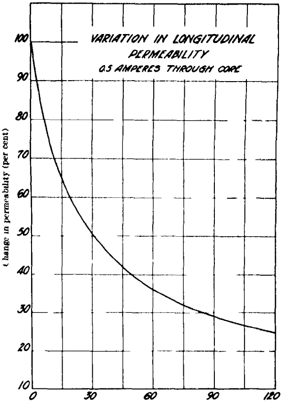

Fig 2

These large variations in inductance obtained as a function of the current through the core or as a function of the degree of twisting of the core while carrying a definite current appear to have many possible applications

A complete account of this work covering all of the more common ferromagnetic materials will be given elsewhere

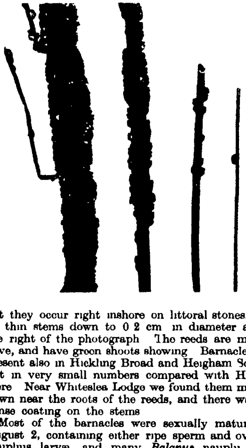
Barnacles in Horsey Mere

On July 15, 1938, it was discovered that there were large numbers of the barnacle *Balanus improvisus* Darwin, living on the stems of the reeds in Horsey Mere, Norfolk The water of Horsey Mere and Hickling Broad has been very saline since the sea broke through last spring on February 12, March 1 and April 4 and estimations of the salinity of the surface water on August 6, made by Mr A J Rudd of the Norfolk Fishery Board were Horsey 18 19 per mille, Hickling varying from 21 0 per mille (north end) to 17 5 per mille (Whiteslea)

The fauna of the area is now an interesting mixture of brackish water and freshwater species On August 2, the following species were found amongst the reeds on which the *Balanus* occurs *Hydrobia jenkinsi* Smith*, *Bythinia tentaculata* (L)*, *Theodoxus fluviatilis* (L)*, *Gammarus zaddachi* Sexton*, *Corophium volutator* (Pallas)*, *Sphaeroma* sp , *Membranipora monostachys* Busk, var *fossularia* The only aquatic insects found were larvæ and pupæ of *Donacia cinerea* Herbst, which were fairly numerous on the roots of the reeds

In Horsey Mere the barnacles appear to be distributed all over the reed beds and are very abundant The greatest density occurs next to the open water, where thick stems and rhizomes of *Phragmites communis* and *Typha* are often completely covered in barnacles from a depth of six inches downwards, as on the left of the accompanying photograph Inside the reed beds they become more scattered, but they occur right inshore on littoral stones, and on thin stems down to 0 2 cm in diameter as on the right of the photograph The reeds are mostly alive, and have green shoots showing Barnacles are present also in Hickling Broad and Heigham Sound, but in very small numbers compared with Horsey Mere Near Whiteslea Lodge we found them mainly down near the roots of the reeds, and there was no dense coating on the stems



Most of the barnacles were sexually mature on August 2, containing either ripe sperm and ova, or nauplius larvæ, and many *Balanus* nauplii were found in the plankton of Horsey Mere Taking the carino rostral diameter as the index of size, the specimens are up to 1 1 cm , and the average of fifty examples, which were chosen as not being deformed through overcrowding, is 0 83 cm The maximum size of the specimens collected on July 15 is 0 9 cm , but the average of fifty is only 0 57 cm A few young individuals, less than 0 3 cm , were found on both dates, and these must represent the first of the second generation

Gurney[1,2] records this species in the Bure opposite Muck Fleet, where the water is 'generally almost fresh" It is possible that the nauplii reached Horsey by the Thurne, which is a tributary of the Bure, on an abnormally high tide, but the fact that the adults are so abundant in Horsey, and comparatively scarce in Hickling, suggests that they came direct from the sea during one of the break throughs in the spring A few *Balanus* nauplii were found in a sample of the plankton from Horsey Mere on February 20. Nauplii of *B improvisus* have been recorded in the Zuider Zee as early as January 6, and so they may have reached Horsey during any one of the three break throughs Breemen[3] has shown that individuals of this species may contain embryos three months after they have settled

It seems that *B improvisus*, which is a southern species, is killed by too low temperatures, so the barnacles may be killed off if there is a sufficiently severe frost at Horsey this winter On the other hand, it is a very euryhaline species, and occurs in Holland in water of salinity down to 1 65 per mille, so that so far as salinity is concerned this species will probably survive in Horsey Mere and Hickling for several years Now that it is so well established, it might even survive there under normal conditions, since the water is always slightly salt

Irritant Exudation from a Millipede

WHILE working at Sigi, 1,500 feet below the East African Agricultural Research Station at Amani Tanganyika Territory, one evening in June, I came across one of the giant black millipedes—a species of *Spirobolus*—which are fairly common in this region of tropical evergreen rain forest It was an unusually large specimen, fully twelve inches in length Having no box capable of holding it, I buttoned it up in my hip pocket and continued my work for an hour or so

I felt the millipede moving about in my pocket and noticed that I was becoming rather sore in that neighbourhood, but paid little attention to it However, whilst bathing shortly afterwards I was surprised to find that my skin had become completely blackened over an area of about nine square inches with further red inflammation spreading rapidly down my thigh Four days later all this blackened skin sloughed away, leaving a raw wound This happened in June 1937, at the end of August 1938 the site of the injury is still visible

I have since examined millipedes of the same and other species on several occasions, and noticed that, when one is molested by being turned about in the fingers, small drops of liquid are exuded from pores, one on the side of each segment This liquid is rich yellow brown in colour and stains the fingers like iodine, it has a characteristic pungent odour recalling that of nitrogen peroxide, but is neutral to litmus The fumes cause marked watering of the eyes Mere contact of the fluid with the tough skin of the fingers produces no injurious symptoms, although when some was rubbed on to the skin of the leg, smarting was experienced and the skin eventually became hard and scaly

Record of *Typhlocaris Galilaea*

Two specimens of the blind prawn, *Typhlocaris galilaea*, were obtained recently from the cistern of the water mill near Tabgha at the north end of the Sea of Galilee This species had been reported as being exterminated by drainage operations It appears probable that the species normally inhabit a dark cave or grotto formed by a hot sulphur spring and the specimens obtained by me were stragglers which were carried out into the cistern

Isolation of an Anhydro *l* Galactose Derivative from Agar

IT has been found possible to methylate agar by direct treatment of the polysaccharide with methyl sulphate and sodium hydroxide solution The product had OMe 33 0 per cent $[\alpha]^{18^\circ}_{D}$ −93 1° in chloroform and it contained no sulphur

Methylated agar is easily hydrolysed by boiling with 2 per cent methyl alcohol hydrogen chloride and the hydrolysate contains little or no methyl lævulinate Thus, the hydrolytic products from methylated agar (14 gm) contained only a very small amount of ester which was separated as the barium salt (0 18 gm) The mixture of glycosides was separated, by distillation into three fractions Fraction 1 was a mixture of the α and β forms of 2 4 6 trimethyl methyl-*d* galactoside identical with that already separated by Percival and Somerville[1] from methylated agar Fraction 2 was a mixture of 1 and 3 Fraction 3 was collected in five successive fractions the constants of which were sufficiently close to warrant the assumption that no great difference in composition existed among them OMe 37–40 per cent On further methylation with methyl iodide each of these sub fractions yielded a crystalline derivative which had the composition of a dimethyl anhydro methylhexoside It is recognized as 2 4 *dimethyl* 3 6 *anhydro methyl* l *galactopyranoside* for the following reasons

It shows the properties characteristic of 3 6 anhydro methylhexosides (cf Peat and Wiggins[2]) in that it is hydrolysed by cold acid and is unaffected by prolonged boiling with sodium methoxide solution It was possible to compare the substance with 2 4 dimethyl 3 6 anhydro methyl *d* galactopyranoside which had been synthesized in this laboratory for another purpose (Haworth Jackson and Smith unpublished work) The comparison established that the two were optical enantiomorphs

	Product from agar	Synthetic product
Melting point	82 83	8 83
$[\alpha]_D$ in chloroform	+8 3	86 6
$[\alpha]_D$ in water	+73	76
$[\alpha]_D$ in cold dil sulphuric acid	7 8 → 1	69 4 → +20

Dr L G Cox of this Department reports The complete identity of the X ray photographs of single crystals of the two substances coupled with the rotational data given above shows that the two are enantiomorphs Further calculation of the molecular weight from the X ray data indicates that the substances are monomeric in the crystalline state

Hydrolysis of the galactoside from agar yields 2 4 *dimethyl* 3 6 *anhydro* l *galactose* m p 114° The corresponding product from the synthetic *d* galactoside has m p 11 °

The existence of *l* galactose in agar was demonstrated by Pirie[3] who isolated hepta acetyl *dl* galactose by the acetolysis of agar, and experiments are now in progress to determine whether the 3 6 anhydro ring structure which is present in methylated agar exists preformed in the original polysaccharide

Isolation of an Anhydro-Sugar Derivative from Agar

SINCE by the kindness of Prof W N Haworth we have learnt that a publication on agar is shortly to appear from the Birmingham laboratories* we feel it desirable that one aspect of our researches on the subject should be communicated here

Accompanying the 2 4 6 trimethyl methyl galactoside obtained by the hydrolysis of methylated agar with methyl alcoholic hydrogen chloride, we reported[1, 2] the presence of a syrup (c 25 per cent) which appeared to be a dimethyl methylketoside Further work has now shown that this portion is not homogeneous since it can be partially separated into two fractions by extraction with boiling light petroleum, and these fractions in turn are also mixtures The portion insoluble in light petroleum ($[\alpha]^{20°}_{D} = -20°$ in chloroform), on complete methylation can be divided into two fractions, a crystalline body (X), and an oil, whilst the soluble portion ($[\alpha]^{20°}_{D} = +40°$) can be distilled in a high vacuum to yield two fractions (A) of b p 160°/0 09 mm (bath temp), $[\alpha]^{18°}_{D} = +59°$ in chloroform, and (B) of b p 178° (bath temp)/0 09 mm $[\alpha]^{18°}_{D} = +25°$ Complete methylation of these subfractions gave rise to a mixture of (X) and an oil from (A) and a large yield of the crystalline material (X) from (B) In the same way the syrup obtained from the mother liquors after recrystallization of the 2 4 6 trimethyl methylgalactoside was partially transformed by methylation into (X)

---

* Added on proof Hands and Peat *Chem. and Ind* **57** 937 (1938)

On account of the difficulties in manipulation it is not easy to estimate precisely the yield of this substance (X) but it appears to be about 16 per cent of the weight of methylated agar employed It is non reducing and has b p 85–90°/0 05 mm , m p 81° and $[\alpha]^{20°}_{D} = +75°$ in water and $+85°$ in chloroform Analysis showed it to have the composition $C_6H_7O_3(OCH_3)_2$ and it is therefore a dimethyl anhydro methylhexoside It gave a strong Seliwanoff test and simulated a furanoside on account of the ease of removal of the glycosidic residue by dilute mineral acid , it was found that hydrolysis to the free anhydro sugar ($[\alpha]^{17°}_{D} = -23°$) took place by contact for 24 hours with N sulphuric acid This resembles the behaviour of the 3 6 anhydro 2 4 dimethyl methylglucoside of Peat and Wiggins[3], so that although the positive Seliwanoff reaction seemed anomalous, the chance that it might be a 3 6 anhydro galactose derivative was considered By the direct methylation of 3 6 anhydro α methyl galactoside prepared by the method of Ohle and Thiel[4], the corresponding 2 4 dimethyl derivative was prepared This substance was obtained as an oil, b p 90°/0 05 mm , $n^{18°}_{D} = 1\ 4640$ and $[\alpha]^{20°}_{D} = +87°$ in chloroform It is important to note that both these 3 6 anhydro galactosides give the Seliwanoff reaction

Although hydrolysis of the 2 4 dimethyl 3 6 anhydro α methylgalactoside in cold N sulphuric acid was complete in 24 hours the equilibrium value reached was $[\alpha]^{18°}_{D} = +22°$ instead of $-23°$, and although the general properties of the two substances are so similar that it is probable that the natural product is a 3 6 anhydride, it is clearly not 3 6 anhydro 2 4 dimethyl α methyl *d* galactoside, and further synthetic experiments will be necessary to decide its constitution The fact that the specific rotations of the free dimethyl anhydro sugar from agar and of 2 4 dimethyl 3 6 anhydro *d* galactose are approximately equal and opposite in sign makes it possible that the sugar concerned is not *d* but *l* galactose , this sugar has already been found in agar by Pirie[5]

These experiments fail to support the suggestion previously advanced[2] that a ketose is present in the hydrolysis products of methylated agar, although accompanying (X) is an oil of high methoxyl content which may be a fully methylated ketose , but little reliance can be placed on colour reactions in this case since the syrup may still contain a quantity of (X)

It is impossible at present to decide whether the anhydride ring is preformed in agar or whether it is the result of side reactions However, the former view is considered to be the most likely because of the low methoxyl and acetyl contents of methylated and acetylated agar, which can be explained by the presence of the anhydro hexose residues in the chain form each carrying only one hydroxyl free for substitution The anhydro hexose is clearly not an 'end group since if it were, simple hydrolysis would set free the dimethyl anhydro methylhexoside, whereas actually further methylation is necessary after hydrolysis It is hoped to report upon the precise nature of the supposed 3 6 anhydro dimethyl hexose and of the other unidentified products in due course

Multiplanar Cyclohexane Rings

ON bromination, the isomeric forms of 1 carboxy 4 methyl*cyclo*hexane 1 acetic acid (m p 173° and 137°)[1] furnished monobromo acids, which gave the corresponding hydroxy acids on being heated with aqueous sodium carbonate Oxidation of the hydroxy acids with alkaline permanganate gave rise however, to isomeric forms of 4 methyl*cyclo*hexane 1 1 dicarboxylic acid, which depressed each other s melting points Similar observations were made in the 3 methyl*cyclo*hexane series

A full report of these experiments will be published in due course

Combustion Pressures in Spark-Ignition Engines

IT has come to the notice of investigators interested in combustion and detonation in spark ignition engines that the combustion pressures may attain values which even when no heat losses are considered appeared to surpass those found by calculation making use of the normally accepted data for such processes The inadequacy of pressure indicating apparatus, especially when measurements were made under conditions of incipient or even persistent detonation, has for long prevented adequate attention being paid to this phenomenon

Repeated measurements on different engines with Farnboro quartz and capacity type indicators have now shown that the pressure rise over the compression pressure *may in several cases be up to 50 per cent* higher than is accounted for by classical calculations The extreme cases occur when there is a certain degree of detonation, the phenomenon being then sometimes, though not always accompanied by superimposed pressure vibrations , when these vibrations occur, the value cited relates to the mean value of the pressure

These pressures being sustained beyond the period of vibration either of the gas mass or of the indicator they must be considered as static pressures, to be accounted for by external energy of the combustion gases, for which it may be assumed that temporarily the specific heat of the combustion gases is much lower than normal This may be explained by an excitation lag theory[1], which states that in the case of combustion imparting chemical energy to a gas other than monatomic, this energy is first absorbed as translatory energy It may be thought that this would apply especially in the case of the nitrogen of the charge Both the pressure of the gas and its rate of heat transfer to the combustion chamber walls being dependent on the translatory energy, these findings may explain to some extent the mechanical and thermal damage due to detonation

Vitamin E Deficiency in the Suckling Rat

In a paper recently published[1] I have shown that the characteristic defects in the offspring of vitamin E deficient rats may be cured by administering to them concentrates of the vitamin It seemed important to confirm that this curative action is due to vitamin E and not to some other constituent of the concentrates derived from natural sources This I have now done by administering 2 milligrams of synthetic *d l* tocopherol (Roche) to the offspring of vitamin E deficient rats

This further observation that the synthetic vitamin produces the same curative effects as the concentrate from natural sources taken in conjunction with my previous publications shows conclusively that the missing factor in the milk of vitamin E deficient does is vitamin E

Points from Foregoing Letters

By means of a zinc mercury lamp which gives sharp spectral lines without accompanying hyperfine structure components or continuous spectrum Sir C V Raman and C S Venkateswaran find that the light scattered backwards by glycerine and by phenol exhibits well defined Brillouin components on either side of the incident lines The authors infer that the viscosity of glycerine, as usually measured has little influence on the propagation of thermal compression waves of very high frequencies

Prof J B S Haldane gives a formula for the probability that a given individual would be killed by an explosive bomb and calculates roughly the efficiency of various types of shelters and trenches against light and heavy bombs

A graph is submitted by Dr L F Richardson showing that during the arms race of 1909–13 the increase in expenditure for armaments of France Russia, Germany and Austria combined followed a linear relation with reference to time Dr Richardson connects this with his previously deduced formula expressing the interaction of fear with cost and with grievances in international relations

By means of paraffin absorption measurements, A E Downing and Prof C D Ellis estimate the position of the resonance levels for slow neutrons in several heavy elements In bismuth they find two levels (at 1 and 11 volts respectively) corresponding to high excited states of radium E Thorium and uranium likewise show two resonance levels each while with cobalt only one (at about 1 volt) was observed Iodine appears also to have two resonance levels, which might explain the anomalous results recently reported by Michiels

The viscosities of hydrogen and heavy hydrogen gas at various temperatures between 293° K and 14° K have been determined by A van Itterbeek and Miss A Claes They find that at room temperature the ratio between the viscosities is proportional to the ratio of the square roots of the molecular weights of the two molecules but at lower temperature the ratio decreases

The absorption of hydrogen and nitrogen gas by tantalum at very low pressures (clean up) at different temperatures is described by D A Wright The absorption is considerably modified by the presence of surface oxide which explains the various results reported by previous investigators

Large increases in the longitudinal incremental permeability of a wire made of iron nickel alloy (serving as core of a solenoid) is found by J S Webb, when a direct current is passed through the wire so as to produce a superimposed circular field The author submits graphs showing the variation of the *inductance of the solenoid as a function of the direct* current through the conducting core and also the variation of the longitudinal incremental permeability when the core is twisted through various angles

P E Holmes and M G M Pryor report the presence of large numbers of the barnacle *Balanus improvisus* upon reeds in Horsey Mere Norfolk following upon increased salinity of the water brought about by the temporary break through of the sea during the storm of last spring

The percentage ratio of various blood groups among the inhabitants of Khasia and Jaintia Hills Assam derived from an examination of fifty individuals, is given by Captain R N Basu and compared with the blood group distribution among Japanese Negritoes and Indians

S Hands and Dr S Peat report the presence in methylated agar agar of a derivative of 3 6 anhydro *l* galactose which is isolated as the crystalline dimethyl 3 6 anhydromethyl *l* galactoside Evidence is given in support of the constitution assigned to the latter substance E G V Percival, J C Somerville and I A Forbes have likewise isolated from agar an anhydro sugar derivative which preliminary investigations indicate to be *l* galactose

Research Items

Possession Rite in a Deccan Village

BARA GARI, ' the Dragging of the Twelve Carts a village ceremony, was witnessed by Mr K de B Codrington at Fardapur, a Mahratti speaking community in the Deccan, India, in 1932 (*Man* October 1938) An engagement is made before the shrine of the goddess Marimata, ' the Mother of Pestilence , that the rite will be carried out, if certain prayers are granted This is usually on account of prolonged illness, on behalf of children, or above all because of barrenness In the last event, one of the men of the household must shoulder the undertaking, as only men take part, though the women are profoundly interested, and ceremonially prepare the participants by rubbing them with turmeric The women also make offerings at the shrine The ceremony is evidently a family rite On this occasion six carts only took part They were tied head to tail, the first being an old fashioned field cart with long shaft, obviously necessary for the ceremony At sundown the protagonists were led by their womenfolk to the Hanuman temple, from which all village ceremonies begin Thence they were conducted back to the Marimata shrine by one of its guardians Of the participants two were boys of about nine or ten years old, the third a youth of eighteen Each protagonist was escorted to the shrine between two men holding his arms The youth was already under the influence of possession They entered the shrine, then each came out in turn with his escort and circumambulated the line of carts at a run Each bore a tray with a number of lighted cotton wicks The upper part of the body was then rigid and the eyes fixed The boy on reaching the head of the first cart was lifted in the air by his supporters, and the cart affixed to his waist cloth and waist rope by the loop on the cart shaft, to which two hooks had been fastened The cart then moved forward towards the shrine for about ten yards, accompanied by frenzied shouting and drumming The boy s feet were not on the ground and his body took the strain, while the main motive power was supplied by men pulling on the wheel spokes and others behind the yoke

Prehistoric Cave Men in Texas

A CAVE 45 miles north of the town of Dryden in the West Texas Big Bend country, which was occupied by man at some remote period, has been excavated by Mr Frank M Setzler, of the Smithsonian Institution, Washington, D C In a preliminary report issued by the Institution, it is stated that the evidence of occupation suggests that the cave may have been used for ceremonial brewing It was discovered by Mr Setzler when searching for evidence of an ancient people—the longest headed people yet recorded The slope at the front of the cave was covered with talus which contained large fragments of fire cracked limestone These had been used by the inhabitants of the cave for heating in the fire for cooking purposes and then thrown out The cave was explored by a trench seventy feet long, which was carried to a depth of six feet The deposits included an unusual number of cooking stones, pointing to an exceptional use It is thought this unusual feature of the deposits may have been occasioned by the use of the cave for brewing the juice of the sotol plant to make a fermented drink which the Indians were found to use when the white man first penetrated this country In the deposits were also found cooked animal bones, though these were not so numerous as might have been expected, and hundreds of characteristic arrow heads, scrapers, drills and stone knives

Social Motives in Economic Activities

CLASSICAL economics is largely based on the psychological premise that in their economic activities people shall be considered as solely actuated by the motives of personal material gain During the period of the greatest industrial expansion ever known, this theory expressed and co ordinated the thinking of industry and trade for more than a century , but it has now exhausted much of its usefulness, and in so far as it tends to direct attention away from other factors it has become a danger According to T N Whitehead (*Occupational Psych* , 12 No 4 , 1938), it is necessary to develop an organic conception of society in which economic activities take their place as one important aspect of the whole social process It is impossible to be acquainted with the intimate working of an industrial plant without becoming aware of a complex network of human relations which have no place in the formal organization of the plant and yet without which co ordinated human activity could not take place There is no human motive more widely found or more constantly active than the desire to have a significant place in the group for which the member has a high regard Fundamentally, the urge is to be doing significant things together with other people To insist on the importance of social motives is not to deny the existence of those motives that are predominantly individualistic The writer illustrates by a consideration of the failure of so many wages' schemes based on a too simple application of one motive, and also of high pressure emotional advertising If a small part of the money now spent in industrial research were devoted to the methodical observation of human relations in business, then a social science might be developed of vital importance to our industrial civilization

Secretory Activity of the Liver

THE frog's liver perfused with a saline solution can secrete natural and artificial pigments in concentrations many hundred times those in the perfusate This activity is confined to dyestuffs, some carbohydrates, for example inulin, passing through without any change at all in concentration Höber and Moore (*Proc Amer Phil Soc* , 78, 587 , 1938) have tested the effects of large numbers of organic substances on this secretory function of the liver Sugars, polyhydric alcohols and amino acids inhibit liver function, and can be classed generally as substances having a strong affinity for water, as being surface inactive, and as causing dehydration of hydrophil colloids On the other hand, substances which are surface active, such as the salts of the bile acids, the carbamates and saponin, act as stimulants to hepatic secretion The authors suggest that the activity of the liver cells might be regarded as being increased or decreased according as the condition of the cell colloids is altered in the direction of higher or lower dispersion With this idea in view, they have compared the action of these substances on liver secretion with their effects on emulsions of lecithin and on the injury potentials of muscle and nerve In general, there is good agreement Substances which stimulate the liver have been found to evoke injury potentials, and to increase the dispersion of lecithin emulsions and vice versa

Medical Research in South Africa

The work, research and routine, of the South African Institute for Medical Research, Johannesburg is summarized by the director, Sir Spencer Lister in his annual report for 1937 recently published (Johannesburg South African Institute for Medical Research, 1938) Studies on pneumonia and the types of the pneumococcus that occur in natives on the mines, and on prophylactic immunization against pneumonia have been continued A large number of rodents examined for the presence of plague infection yielded only three positive results, the smallest figure recorded for positive cases since 1920 The preparation of anti plague serum by means of inoculation with avirulent living vaccine has been shown to yield a serum of greater potency than by other methods A search for bovine strains of tubercle bacilli causing tuberculosis in human beings has been continued, but not a single bovine type has been found among ninety eight strains isolated from non pulmonary cases of tuberculosis, cases which in Great Britain not infrequently yield the bovine type of tubercle bacillus

Transference of Induced Food Habit

The third of a series of papers on the transference of induced food habit from parent to offspring by the late Miss D E Sladden has recently appeared (*Proc Roy Soc*, B, 126, 30, September 23, 1938) Owing to the death of Miss Sladden in 1937, the preparation of the manuscript is solely the responsibility of H R Hewer, who also devised the type of experiments carried out by Miss Sladden and discussed in her previous papers (*Proc Roy Soc*, B, 114, 441, 1934, 119, 31, 1935) This paper now records the results of a series of experiments carried out by Miss Sladden over a period of six years Two sets of stick insects, one reared on privet in every generation but tested for their ability to accept ivy in each generation, the other reared on ivy in every generation after having been tested for their ability to accept it by identical tests, have demonstrated different relative tendencies to accept ivy as a food plant Those forced to eat ivy from the first generation onwards rapidly developed an increased ability to accept this food plant Those reared on privet continuously displayed, during the first four filial generations, an increased ability to accept ivy but to a much less extent than did the ivy fed stock In the fifth and sixth filial generations ability to accept ivy displayed a decrease and a distinct annual periodicity which is only slightly shown by the ivy fed stock It is concluded that the forced ivy-feeding has induced in the stick insect the increased ability to accept ivy in succeeding generations

Humus and Plant Resistance to Disease

Under a different title (Insects and Fungi in Agriculture), Sir Albert Howard has recently published a very stimulating discussion of this topic (*Empire Cotton Growing Rev*, 15, July 1938) His thesis is that insects and fungi are not the true causes of plant diseases, these result from poor nutrition, disease resistance being the natural reward of healthy and well nourished protoplasm "The first step is to make the soil live by seeing that the supply of humus is maintained Sir Albert then stresses the significance of the return of humus to the soil by means of the conversion of vegetable refuse into humus as in the Indore process He points out the remarkably rapid improvement resulting when humus is applied to derelict plantations of tea, rubber etc results that are so striking that it is difficult to attribute them to the response of the crop to better soil tilth etc He concludes that the effect must be connected with the proper development of mycorrhiza in the roots, and during a recent tour of tea plantations in India and Ceylon, in co operation with Dr Rayner, he obtained additional evidence pointing in the same direction Sir Albert suggests that the fungus component may enable the rapid transfer of accessory growth substances from the soil to the host plant but this ingenious suggestion remains at present purely speculative

Inducing Polyploidy by the Use of Colchicine

The recent introduction of colchicine as a means of inducing polyploidy has led to many experiments with various plants Dr H Dermen (*J Heredity*, 29, No 6) has recently described experiments and summarized the literature Aqueous solutions of colchicine ranging from 0 1 to 1 per cent were applied to buds of *Rhoeo discolor* with a camel hair brush All parts of the flower were affected, but the effect was most striking in the filamentous hairs on the stamens, the end cells being affected most of all In material collected eight days after treatment, one end cell had undergone three successive doublings of the chromosomes increasing the number from 12 to approximately 96 Other cells in the same hair had only been doubled once or twice In somatic cells of the anther, cells were observed having about 32*n* and in one case 64*n* chromosomes, indicating as many as five successive divisions of the chromosomes without cell division, owing to destruction of the spindle mechanism The meiotic chromosomes normally form a ring or chain of twelve The treatment caused the formation of 4*n* cells with univalent chromosomes and other abnormalities Pollen grains were produced which judging from their size, were *n*, 2*n*, 4*n* and even 8*n* Diploid pollen grains were also obtained by changes of the plants from greenhouse temperature to cold or warm There was a lowering in the viscosity of the cytoplasm, which remained more fluid even after cell division was resumed Suggestions are made for producing polyploid pollen grains, embryos seedlings and growing tips by colchicine or temperature changes

Travel-Times of the Seismic Waves *P* and *S*

Up to, and including, the 1929 readings, the Zöppritz Turner tables were used at Oxford for the reduction of observations and determination of epicentres for the International Seismological Summary For the 1930 readings and afterwards, the Jeffreys Bullen tables have been used The change was necessary on account of errors in the older tables brought into greater prominence by improved instrumental performance at observatories throughout the world Dr A W Lee has now performed a very useful service to seismology by examining critically the I S S published data for well observed 'normal focus' earthquakes for the years 1930–31 (Meteorological Office *Geophys Mem* No 76, 9, 1938) It was found that for the 146 shocks considered, the travel times of the *P* waves agreed well with the Jeffreys Bullen 1935 tables The travel times of the *S* waves were rather different, and departures from the tables were examined for errors in identification, variations in focal depth, and errors in the tables In this work recourse was also made to original seismograms obtained at Kew It was determined that the *S* observations are generally later than the tabulated times at distances less than 28°, but beyond this they agree better with the tables as amended by Jeffreys in 1936 For epicentral distances less than 12° there may be confusion in identification owing to the pulses arising from reflections and refractions within the granitic, intermediate and basic layers of the earth s crust Between 12° and 28° it is now generally agreed that there is often a small pulse preceding that usually called *S* Lee prefers to continue calling the large easily recognized pulse *S*, and, although he does not discuss all the possibilities with regard to the preceding pulse, makes a very important statement that all discontinuities in the earth need not necessarily be horizontal ones In view of the above deviations of the 1930–31 observations from the Jeffreys Bullen 1935 and Jeffreys 1936 tables, Lee gives a new table for *S* His table for *P*, *S*, and *S–P* differences should be very useful to observers at stations who are required to give details of an epicentre quickly without communicating with other observatories

Geocentric Distances in Seismology

Since the advent of frequent radio time signals and greatly improved timekeeping, the arrival times of various earthquake waves at observatories have been much more accurately determined, and at most observatories can now be determined accurately to a fraction of a second This makes apparent certain systematic errors in the determination of epicentres, and one of these is concerned with the departure of the figure of the earth from a true sphere It has been suggested that one method of circumventing this is to use geocentric instead of geographic co ordinates for this work In order to facilitate the change over from geographic to geocentric co ordinates, and afterwards to use geocentric co-ordinates, Dr K E Bullen, of Auckland, New Zealand, has produced in recent years a number of very valuable tables One was ' Tables for Converting Geographic into Geocentric Angular Distances" published by the British Association in 1938 The latest is 'Tables for Reduction of Apparent Travel times of Seismic Pulses PKP, PKP$_2$, SKS (corresponding to the use of Geographic Latitudes) ' This is printed as *Bulletin* No 134 of the Dominion Observatory, Wellington, New Zealand (extracted from *New Zealand J Sci and Tech* , 19, No 11, 708–18 , 1938)

Anomalous Spark Discharges between Large Electrodes

In the official overseas edition (in English) of the September issue of the *Journal of the Institute of Electrical Engineers of Japan*, there is a suggestive paper by Y Ishiguro and Y Gosho on the anomalous spark discharges which sometimes take place between large electrodes when the distance between them is large The curves connecting the disruptive voltages with the distance between the electrodes, instead of being smooth, are sometimes irregular, for which there seems no obvious explanation Until quite recently, it was customary to neglect entirely the anomalous points on these curves From the point of view of ordinary high voltage engineering, a method of computing the potential gradients for anomalous results had not yet been found In 1929, Carrol and Cozzens published through the American Institute of Electrical Engineers some anomalous results obtained with spherical electrodes Ishiguro and Gosho find with disk electrodes of great size very pronounced anomalous results The disks are curved slightly at the edges They have found that the phenomena varied from day to day If the electrodes were left idle for several days, the only treatment received being the wiping away with a clean cloth of the visible dust which had accumulated on them, the experiments showed that the anomalies were greater in some cases than in others In one experiment the maximum anomalous voltage was 124 when the normal voltage was 346 The authors have made an attempt to calculate accurately the maximum potential gradient when anomalies occur. Toepler s explanation given in 1932 applies well to the author s experiment, but unfortunately, in his own experiments in order to obtain larger effects, he had sprinkled dust particles on the electrodes, whilst in the authors experiments they kept the electrodes clean They have found that the anomalous results may be decreased either by coating the electrodes with transformer oil or with carbon tetrachloride liquid

Suggested Relativity Experiment

In Nature of July 2, p 40, a letter was published from Mr F H C Smith suggesting that a test of the relativity postulate that the speed of light is independent of the motions of its source and of the observer, should be made by measuring the speed of light from approaching and receding stars by Anderson's development of the Kerr cell method Sir Shah Sulaiman reminds us that he also considers the use of non terrestrial light as of fundamental importance in testing relativity In his paper (*Proc Nat Acad Sci India*, 7, 85 , 1937) he declared "for this experiment [the Michelson Morley experiment] monochromatic light produced on the Earth has been used so far any experiment in which *terrestrial* light is used is inconclusive and does not therefore prove the postulate of Relativity Light from the Sun should first be passed through a series of prisms (as in a monochromator), then all other light, except that with the chosen wavelength, intercepted by obstacles, and only nearly monochromatic light allowed to fall on a plane reflector and then directed into the Michelson-Morley Apparatus Although the intensity will be diminished, there will be a greater facility to observe the interference fringes I earnestly appeal to experimenters to repeat the experiment with Solar Light I venture to make the prediction that *there will no longer be the null effect* '

Weather Prediction in India

A SYMPOSIUM on weather prediction was held at Poona on July 25–26 under the auspices of the National Institute of Sciences of India The problem was discussed in its various aspects, namely, seasonal forecasting in India, air mass analysis and short period weather forecasting with special reference to the forecasting of nor' westers in Bengal, use of upper air data in weather forecasts, latent instability in the atmosphere and its consequences, rainfall due to western disturbances and the associated upper air temperatures, weather forecasting for aviation with special reference to local forecasts and kinematical methods in weather forecasting

The president, Prof M N Saha in his opening remarks, referred to the development of synoptic charts in India from the time of Blanford and Eliot and to the many new methods in the art of weather prediction introduced in India Dr C B Normand reviewed the complexities of the problem which the meteorologists have to face At one time the practical forecaster could devote most of his time to consideration of rainfall Now airmen want forecasts of upper winds, of height of cloud of fog, dust storms, sudden squalls There is this variety of requirements and yet the decisions of the forecaster have to be made quickly, there is no opportunity for lengthy calculation A hopeful method of analysis one which is now a live issue among meteorologists is to focus attention on the identification of air masses and to picture how the different homogeneous air masses should interact at their boundaries and behave within themselves India is the country in which the subject of seasonal forecasting has been most intensively studied, and yet the utmost one can do at present is to give a very general indication of total rainfall over a large area for a period of 2–4 months The proper assessment of success in weather forecasting is not so easy as one would imagine at first sight Every forecaster—amateur professional or quack—finds some of his forecasts turning out correctly, if he forecasts often enough and yet it is a curious fact, as pointed out by Sir Gilbert Walker some years ago, that 'while the forecasting efforts of a charlatan are judged by their occasional successes, it is the occasional failures of a Government department which are remembered

The first forecast of the monsoon rain which was mainly based on the snowfall on the Himalayas and the Suleman range during the preceding January to May, was issued by Blanford in 1886 Gradually Eliot added other factors, the south east trades at Mauritius, Zanzibar and Seychelles, data from South Australia and Cape Colony, and Nile flood His method involved interpretations that were liable to personal bias The first forecast using a regression equation was made in 1909 by Walker In 1924, Walker worked out six formulæ for forecasting rains in the Peninsula, north east India and north west India, in which use was made of twenty eight factors selected out of a large number after applying his statistical test To these, Field proposed the addition of a factor of special interest, as it indicated the way to a new source of seasonal indicators, namely, the upper winds and the upper air, his prognostic factor for the winter rains over northern India is the upper wind of the autumn over Agra The re examination of the data in recent years, and the application of various statistical tests, have revealed a diminution of the significance of some of the factors Nevertheless, the total correlation coefficient is still 0 63 for the total monsoon rain of the Peninsula and 0 64 for that of north west India and 0 72 for the winter rain of north west India In presenting the above review of seasonal forecasting in India, Dr S R Savur said that the methods of correlation are strictly applicable only when all the quantities correlated are distributed normally To overcome this defect, general methods are being developed The theory, however, is still in its infancy

The method of forecasts for ten day periods developed by Franz Baur of the German Meteorological Service which rests on a combination of statistics and synoptics as well as the composite map method of forecasts developed by Multanovsky and his collaborators, in which the time interval for the forecast is determined by the period which marks the type of the synoptic process involved, were explained by Mr S Basu from the point of view of their possible application to Indian conditions

Air mass analysis received a good deal of attention Dr S N Sen explained the methods adopted in India for the identification of the different air masses, these are, broadly speaking, of two classes, oceanic and continental, but it is possible to divide them into several sub classes He showed certain types of stationary fronts which often develop over the Indian area

A great help in identifying the different air masses is the drawing of stream lines and trajectories of air at different levels deduced from pilot balloon and cloud movements a method which is now in daily use Information about upper air temperatures and humidities whenever available helps to make the identification more certain Dr K R Ramanathan explained how warm fronts somewhat similar to those met with in European latitudes are associated with depressions and storms in the Bay of Bengal The two air masses between which the front forms in the Bay of Bengal are the dry, cold air from north India and the moist equatorial air from the south Bay of Bengal A modified type of front' or partition zone is associated with storms of the pre monsoon season Monsoon depressions tend to form on the zone between fresh monsoon air and old monsoon air, the former behaving as a cold mass and the latter as a warm mass Dr S K Pramanik gave an application of air mass analysis to the problem of forecasting nor' westers in Bengal, and Mr S P Venkiteswaran discussed certain relationships between upper air temperatures over Agra and distribution of rainfall during passage of western disturbances

The role of latent instability in the atmosphere in the development of thunderstorms, dust storms, etc, formed the subject of an interesting communication by Dr N K Sur This term (defined by Normand in Nature of October 3, 1931, p 583) refers to a certain thermodynamical state of the atmosphere in which, in suitable circumstances, an expenditure of a small amount of energy leads to a release of a large amount of energy Absence of latent instability is associated with dry fine weather with occasional high clouds of non convectional type, and its existence usually with convective types of clouds like cumulus or cumulo nimbus or with dust or thunderstorms

Mr Krishna Rao discussed the problems which arise in weather forecasting for aviation, which can be classified into three categories, regional, route and local In forecasting radiation ground fog, the 'Taylor diagram' has not proved very useful in India except that it can be used to rule out days when fog is unlikely Daily tephigrams based on aeroplane soundings constitute the most valuable items in forecasting convectional phenomena, formation, clearing or persistence of clouds

The kinematical methods in weather forecasting developed by Dedebant and Pettersen also received attention Whenever any pressure system, such as a cyclone, an anticyclone, a trough or a front, is in continuous motion, one can, from a knowledge of the changes that have taken place in the system in the previous two or three hours, calculate the velocity and acceleration of each point of the system and thus determine the position as well as the configuration of the system during the next 6 or 12 hours The deepening or filling of pressure over an area bounded by two closed isobars is equal to the planimetric value of the barometric tendency within the same area Dr S K Banerji gave an application of these and other kinematical laws to certain Indian storms, particularly to explain the curvature of their tracks

In winding up the discussion, Dr Normand referred to the future of weather forecasting He said that it seems doubtful whether the statistical methods applied to surface data will result in any appreciable improvement of seasonal forecasting The region where we have to look for the improvement of forecasts of all kinds from short to long range is the upper air More data by aeroplanes, *radio sondes* and balloon meteorographs are needed both in day to day analysis of the weather situation and in the search for factors of use in seasonal forecasting

---

Engineering Research and Soil Corrosion

IN February 1935, the Council of the Institution of Civil Engineers adopted a more active policy in regard to engineering research and constituted a Research Committee with wide terms of reference Previously, specific problems had been investigated by committees appointed specially for each case, and their work produced results of great importance The growth in scientific knowledge and in the size and complexity of the problems confronting the engineer and also the great changes which have been effected in the materials with which he has to work, brought about a realization of the necessity for greater understanding of the scientific basis of engineering practice The Committee was entrusted with the duties of making recommendations of subjects for research and investigation, and of maintaining contact with other bodies engaged in similar work While it has mainly limited its activities to problems in branches of engineering not ordinarily included in the programmes of the more specialized institutions, it has actively co operated with many of these in researches of common interest

The report of the Committee for the years 1935–36 and 1936–37 has now been issued[1] The general policy has been to make use of the existing research organizations such as those of the Department of Scientific and Industrial Research, and of the universities and technical colleges, and no attempt has been made to set up an independent laboratory The researches in which the Committee is in this way taking part are classified under the general headings materials, soil mechanics, hydraulics, structures, and specialized engineering practice—and it will be of interest to those engaged in other branches of science to learn of the inclusion of such subjects of investigation as the most desirable types of fish passes in rivers and the practice to be prescribed for the use of self contained breathing apparatus in sewers and other engineering works None of the investigations has as yet been completed but, from time to time, in the *Journal* of the Institution, in the proceedings of other societies and in the technical press, reports of progress or of partial results have been published

Part 2 of the report gives detailed accounts of the progress of the researches undertaken One of these deals with Soil Corrosion of Metals and Cement Products The increasing occurrence of reports of severe corrosion of concrete in clay soils containing sulphate salts has shown the need for more information than is at present available as to the conditions which are potentially dangerous and as to the most effective protective measures After a questionnaire had been circulated to engineers throughout Great Britain inquiring into the prevalence of corrosion and the type of soil in which it was found, it became evident that the research ought to be organized on a wider basis, and a new committee was formed to include members from the Iron and Steel Institute, the British Non Ferrous Metals Research Association, the National Physical Laboratory, the Building Research Station and the Rothamsted Experimental Station Considerable financial support is being given by manufacturers and organizations interested in cement and concrete, and a scheme of research extending over ten years has been envisaged

From a study of the work already recorded, it has been made evident that the corrosion of metals is far more dependent upon the nature of the soil, its composition and physical condition in respect of perviousness, moisture-content, etc , than upon any variations in type of ferrous metal or in the state of a non ferrous metal A necessary preliminary to the consideration of tests on various metals is therefore the decision to concentrate attention on conditions of environment, for which purpose a special subcommittee has been formed

A separate research on the subject of "Vibrated Concrete" has yielded several interesting results From the work so far carried out, it appears that the properties of vibrated concrete are merely those of a concrete in which satisfactory consolidation has been obtained with mixes which are drier than those associated with hand-compacting The method thus extends the range of water/cement ratios towards lower limits than were previously practicable, with the results that strength and density can be improved, shrinkage and creep are reduced, and the bond with reinforcing steel is increased

In 1932, research on the stresses set up during the driving of reinforced concrete piles was commenced at the Building Research Station and was carried on in collaboration with the Federation of Civil Engineering Contractors It was initiated as a direct result of the difficulties experienced under certain conditions of hard driving, where it was found impossible to comply with the specification and at the same time to avoid serious damage to the pile This is one of the investigations in which the Civil Engineers' Committee is now co operating and as it happens, the report of the research work carried out has also recently been issued[2] In and around London there are many building sites where the ground consists of alluvial or made up soil of very low bearing power for a depth of 10–30 ft Below this is a stratum of hard compact gravel the thickness of which on any one site may vary from a foot or two to so much as 20 feet Under the gravel, soft earth of low bearing power is again found and at a still greater depth the hard compact clay is reached The uncertainty of the gravel stratum as a foundation for important structures has made it advisable to found on the hard clay It is in the penetration of the gravel that the difficulties referred to have been experienced, and excavation of driven piles has revealed unsuspected damage underground Uncertainty was, in consequence felt as to the condition of piles driven on such sites The current theory assumes uniform stress distribution through the pile, but, as the velocity of stress propagation in a reinforced concrete pile is approximately 12 000 ft per second, research was necessary This involved an examination of the nature and magnitude of the stresses induced in piles by impact, a study of the effect upon impact resistance of the design and methods of manufacture of the pile, and the development of means of indicating dangerous conditions during driving

In addition to a number of facts of the highest practical importance which have emerged from the research, as to both the conditions which arise and the best methods of driving, a mathematical theory is outlined which is shown to conform to the results of the experimental investigation in all its main conclusions and to be applicable to estimate the stress at any point under known conditions An expression is given for the Young's modulus of an equivalent homogeneous pile, but, as the mathematical expressions for the stresses are too complicated for practical use, the results have been given in the form of charts showing the maximum compressive stresses at the head and foot for different weights of hammer, stiffnesses of cushion, etc Further research is suggested and it is obvious that one of the chief sources of uncertainty and trouble is the unsatisfactory nature of existing methods of cushioning the blow A head cushion of constant properties and capable of ensuring a uniform distribution of stress over the pile head would not only prevent the majority of head failures but also would enable data to be collected on bearing capacity under controlled head conditions Of the packings in common use which were tested in the special impact machine, sackcloth has so far exhibited the best characteristics

---

Training and Research in Electrical Engineering

DR A P M Fleming, in his inaugural address to the Institution of Electrical Engineers on October 20, discussed the progress made in the methods of selecting the personnel required for the electrical engineering industry and the methods employed to develop scientific discoveries In former days, ideas were conceived and developed by the individual effort of men of genius, to-day, in the universities and great scientific laboratories, teams of scientific workers are at work, extending the boundaries of knowledge, out of which possible applications in industry may emerge The great manufacturing organizations find it necessary to be continually increasing their technically trained staff and to engage men of wide scientific attainments so as to apply the knowledge that practical research yields

Many of the new discoveries affecting our industry arise from the work of the physicist The field in which the physicist now works has developed in such a manner that, compared with fifteen years ago, he often needs for his researches plant of great engineering magnitude—plant which has to yield hundreds of thousands of kilowatts or many millions of volts On this account, as well as for other reasons, it is probable that the great manufacturing organizations will undertake more and more fundamental research

A pleasing feature during the last ten years has been the tendency towards co operative research whereby problems of common interest to a large number of different organizations are pooled This avoids overlapping of effort and has enabled the smaller concerns to profit equally with the large ones for the knowledge thus revealed is available to all on the same common basis as a raw material supply A great deal of the responsibility for continued technical development falls on the manufacturer The manufacturing branch of the electrical industry now employs 70 per cent of all the workers engaged in electrical applications

There are three principal educational levels of entry into the electrical industry In the lowest of these are those youths who are recruited at ages between fourteen and sixteen years from the elementary, central, junior technical and junior secondary schools, the intermediate level comprises those of sixteen to eighteen years of age, who have reached matriculation or higher school certificate standard in secondary schools, whilst in the highest level are those who enter as graduates from the universities and large technical colleges

The electrical profession is a democratic one, in that no matter what the educational level of the entrant is, he can, if he has the requisite ability and ambition, climb to the highest ranks The importance of attracting the very best recruits from each level and of encouraging, and affording facilities for, the upward mobility of the individual according to his aptitude and capability, cannot be over estimated

The question of the selection of a recruit for a particular post is most important Dr Fleming is of the opinion that for most types of industrial employment the best results are obtained when methods of self selection are employed and the entrant is given an opportunity after he has had some manufacturing experience under sympathetic guidance, of deciding for himself the branch of works to which he is best suited An increasing number of youths entering from the lowest educational level secure promotion through following a course of technical study leading to national certificates There is now an increasing tendency on the part of employers to permit their apprentices to attend equivalent part time day courses in the local technical institutions

This democratic tendency is in sharp contrast to the system in operation in Germany where, for the most part, the upper level attainable even by an ambitious youth is dictated by his starting level This restricting feature must react on the enthusiasm of one forced to resign himself to a predetermined status with little if any prospect of further advancement The U S S R plan has certain political limitations, but it endeavours to select, educate and train its entrants to industry, solely on the basis of merit with a considerable amount of success

University Events

LEEDS—Dr P L Sutherland has been elected to the chair of forensic medicine in succession to the late Prof Maxwell Telling Prof Sutherland, a graduate of the University of Glasgow, has held an appointment in the University as lecturer in the pathology of industrial diseases since 1920 He has been since 1910 pathologist to the West Riding County Council a post which he will continue to hold

LONDON—Dr Harry Jones has been appointed as from October 1 to the University readership in mathematics tenable at the Imperial College—Royal College of Science During 1933–37 he was lecturer in theoretical physics in the University of Bristol, and since October 1937 he has been attached to the Royal Society Mond Laboratory in Cambridge

Mr F W Paish has been appointed as from October 1, 1938, to the Sir Ernest Cassel readership in business finance tenable at the London School of Economics Since 1932 he has been one of the Sir Ernest Cassel lecturers in commerce at the School and also secretary of the London and Cambridge Economic Service

The following titles have been conferred in respect of posts held at the institutions indicated professor of Near Eastern archæology on Mr Sidney Smith (Institute of Archæology), reader in electrical engineering on Dr H E M Barlow (University College)

Science News a Century Ago

The Ashmolean Society

AT a meeting of the Ashmolean Society, Oxford, on October 29, 1838, Prof Baden Powell read a paper entitled 'On Refractive Indices" The object of this communication was to state the results of a series of observations, in which the author had been engaged during the summer, in extension and verification of his former researches Besides the general object of more accurate determination of refractive indices for definite rays in several important media, he had in view the settlement of some points on which questions had been raised, and in some preliminary remarks, he adverted especially to certain objections raised by Sir David Brewster at the Newcastle meeting of the British Association At Newcastle, Powell had read a paper entitled 'On Some Points connected with the Theory of Light while Brewster had read another entitled 'On a New Kind of Polarity in Homogeneous Light" In the discussion on those papers there was a marked difference of opinion and this found expression also in the pages of the *Athenæum* after the reading of Powell s paper to the Ashmolean Society

The Zoological Society

AT a meeting of the Zoological Society on November 1, 1838 the annual report which was read, stated that the receipts for the year up to October 31 amounted to £13,230 and the expenditure to £10,997 leaving a balance of £2,232 The council had determined upon an alteration in the mode of introduction to the gardens on Sundays Each fellow was to have a ticket for his own personal use and two checks for the admission of friends

Henry's Electrical Researches

ONE of the most important memoirs of Prof Joseph Henry of Princeton College, was that On Electro dynamic Induction read to the American Philosophical Society on November 2, 1838, in which he gave the results of his extension of the purely electrical part of Faraday s Admirable Discovery In his experiments, Henry had employed five different sized annular spools of fine wire (about one fiftieth of an inch thick) varying from one fifth of a mile to nearly a mile in length (which might be called intensity' helices), and six flat spiral coils of copper ribbon varying from three quarters of an inch to one inch and a half in width, and from 60 to 93 feet in length (which might be called 'quantity coils)" These he combined in various ways By the alternations of the ribbon and wire coils, the fact was established "that an intensity current can induce one of quantity, and by the preceding experiments the converse has also been shown that a quantity current can induce one of intensity; a result which has had an important bearing on the subsequent development of the electro magnetic induction coil (W B Taylor s discourse on the scientific work of Joseph Henry) In his experiments, Henry used various batteries, one being a cylindrical battery of one and three quarters square feet of zinc surface another a Cruickshanks battery of 60 elements 4 inches square and another Dr Hare s battery, 32 one gallon jars The investigations were fully dealt with by the French physicist, Antoine C Becquerel, in vol 5 of his 'Traité expérimental de l'Électricité et du Magnétisme"

Science in World Affairs

IN recent broadcast addresses Mr Neville Chamberlain and President Roosevelt have pleaded for peace among civilized peoples by consultation instead of force—whether displayed to produce fear or actually used to oppress or subjugate races or nationalities In the speech which the Prime Minister broadcast at the darkest hour of the recent crisis, he affirmed his conviction that any nation which attempted to dominate the world by fear of its force should be resisted, and that under such a domination the life of people who believe in liberty would not be worth living President Roosevelt stated very clearly the basic principles of permanent peace by which alone can we hope for scientific or any other quality of human progress There can be no peace," he said, "if the reign of law is to be replaced by a recurrent sanctification of sheer force There can be no peace if national policy adopts as a deliberate instrument the dispersion all over the world of millions of helpless, persecuted wanderers with no place to lay their heads There can be no peace if men and women are not free to think their own thoughts, to express their own feelings, and to worship God There can be no peace if economic resources which should be devoted to economic reconstruction are to be diverted to intensified competition in armaments—to a competition which will merely heighten suspicions and fears and threaten the economic prosperity of each and every nation "

It is obvious that the spirit of this declaration is opposed to the urge of nationalism which is now the chief cause of conflicting policies Any nation which separates itself from the rest of the world in the name of race or religion and cultivates ideals of conquest by force in order to impose its beliefs upon others is not promoting social or ethical evolution but retarding it Science has made the world a single unit through the facilities of communication and transport now available and it recognizes no political or racial boundaries in its fields of knowledge To limit study or research in science to any national or racial group, and to disregard other contributions to the progress of natural knowledge, is to betray all that is best in scientific intention Among modern and social intellectual forces, science alone speaks in a tongue which meets with universal understanding if it should ever consent to be coerced into a purely nationalistic policy its suicide is inevitable

What is wanted to day is the international spirit of science in the consideration of problems in which the interests of several nations are involved This, as is suggested in a letter signed by the Archbishop of York, the Bishop of Bristol, Sir Gowland Hopkins, Sir Thomas Holland, Sir Frederic Kenyon, Sir Richard Gregory, Mr H G Wells, and others published in *The Times* of October 29, is the kind of moral rearmament to which attention should be given by all statesmen if rationalism instead of nationalism is to be an effective power in shaping the destiny of mankind The plea made in the letter is for a World Foundation such as has been initiated in the United States by Señor de Madariaga with a two fold purpose (1) to foster the idea of world unity among all peoples, and (2) to promote inquiries directed towards political and economic appeasement on all fronts These two purposes are essentially complementary Only through a new conception of world unity can we override the rock of national bias upon which so many admirable international schemes split

In the development of the social instinct, a sense of consideration for the needs of others has grown from the primitive stage in which it embraced members of the blood kin only, or those of the local group within which the members are more or less intimately acquainted to national groups, and to a commonwealth of nations. A World Foundation would embrace all to whom the dignity of man as an individual entity transcends racial and political boundaries. When such a world commonwealth extends to all men of good will it will be possible to estimate how far the human race has advanced along the road of spiritual as well as material progress. The urge of nationalism and its ideals has diverted the thoughts of peoples in totalitarian States away from the main stream of human progress into narrower channels in which rocks and rapids threaten at every turn to shipwreck all that is best in civilization.

The efforts which scientific workers of any nationality may be expected to make in response to calls for unity and service should have for their ultimate aims a world federation and the preservation of intellectual freedom. Preparations for war, whether limited to the organization of national defence or not, cannot suffice in themselves to meet this present challenge of our day to all that is best in the heritage of mankind. The call which Dr E C Conklin addressed to the American Association for the Advancement of Science last December that those who inherit the tradition of liberty of thought, speech and Press and believe that it is essential to all progress should use their utmost influence to see that intellectual freedom shall not perish from the earth has but gained in cogency from events that have since taken place.

Such freedom is still essential for the advance of science and scientific workers to day may well feel even more than a year ago that the time has come when science should stand openly for freedom especially in countries where force war and civil disabilities leading to exile are used to compel acceptance of political or social creeds. The growing restriction of intellectual liberty is, indeed the most disturbing feature of the present international situation. From many sources before and as well as after the recent crisis have come appeals to rally in defence of liberty and scientific workers have more rather than less reason than the ordinary citizen to respond to that appeal. Science is everywhere the same in aims and methods. Its advance has depended on the contributions of individual inquirers without distinction of race, and anything that limits their contribution or hinders the exchange of views or the contact between different workers impedes that advance.

The greatest problems that confront mankind to day—the promotion of social co operation justice and brotherhood the upholding and development of loyalty to truth and the expansion of ethics until it embraces all mankind are problems which intimately concern science which indeed must bring its own contribution to their solution. There is, however, an even greater challenge. Such problems can only be solved if we zealously guard the freedom and integrity of our thought boldly facing new conditions and meeting every problem without shrinking from difficulties but faithful to the laws which govern our intellectual being.

It is precisely because when freedom of thought and work in scientific research and investigation are threatened their integrity is threatened also that the question is of such vital importance to science to day. Unless the present contraction of liberty is checked the threat to the advance of science and all that it implies for mankind will grow more serious. Already the free intercourse of men of science has been seriously checked both directly and indirectly through the doubts thrown on the integrity of what purports to be scientific work in certain totalitarian States. Even in the remaining democracies the orientation of scientific work is liable to be changed and restrictions imposed if more insidiously on the full freedom of scientific work, through the exigencies of national defence.

With this position no scientific worker who cares seriously for the integrity of his work or the advancement of his science can rest content. Alike in the prosecution of the research directly concerned with matters of national defence as for example in the distribution of population or building or in the objective study of social problems and international relations which are a fundamental part of any policy directed to prevent or eliminate war the principle of intellectual freedom is a vital condition. Violation of this principle injures the whole quality of the scientific contribution and may ultimately destroy it while at the same time it hinders the wholehearted co operation of all scientific workers which is so essential alike in the organization of national defence or a policy for peace.

The defence of intellectual freedom is thus a matter of immediate practical importance to the scientific worker, whether from the point of view of the integrity of his particular science or his response to the call for national service. He must neglect no opportunity either as a citizen or as a professional man of urging support for a policy which fully safeguards such freedom and be prepared to co operate with any national movement which aims at ensuring this essential principle of progress He should also be prepared to accept his share in the task of rehabilitating the many men of learning whose work has been interrupted by violation of this principle in other countries Equally he should be prepared to take his part in the clear thinking required to formulate sound principles of relations between the scientific profession and the State and to accept loyally the discipline or code of ethics thus evolved Nor must he fail to uphold the principle of supreme loyalty to truth essential no less in the smallest scientific investigation than in the broad programmes of objective research into social and international problems which must be pursued if we are to build a world order from which the fear of war and the wastage of armaments is ultimately banished

Seasonal Periodicity of Malaria

The Seasonal Periodicity of Malaria and the Mechanism of the Epidemic Wave
By Dr Clifford Allchin Gill Pp xi+136 (London J and A Churchill Ltd 1938) *10s 6d*

THE discovery by Ross of the mosquito cycle made it possible for the first time to explain a host of facts in the epidemiology of malaria which otherwise were entirely inexplicable It very soon became evident that malaria instead of being contracted from man s general surroundings in Nature as up to then had been supposed was merely a special case of a man to man infectious disease differing only from other infectious diseases in that an intermediate insect host was required for its transmission That the insect host was a necessary factor did not at first presuppose any very complicated relationship in this respect If there was no vector there would naturally be no malaria but other things being equal the amount of malaria might be expected to be in proportion to the numerical prevalence of the incriminated insect

This relatively simple outlook was soon found however to be far from an adequate one and the history of malaria investigation has more and more shown how complex are the factors which determine malaria prevalence Especially have recent researches shed unexpected new light in this field In the book under notice Colonel C A Gill gives a very clear and readable exposition of some of these new additions to knowledge Malaria does not merely show different degrees of prevalence in different regions of the earth it exhibits also peculiarities in the different terrestrial zones which can be described and defined

It is one of the merits of this small volume that it has for the first time clearly and interestingly given both the limits and the reasons for the existence of these zones The zones are essentially related to temperature and humidity the different combinations and permutations of which acting through the insect vector the human host and the parasite bring about special features which characterize each zone Thus below a certain critical summer temperature *Plasmodium falciparum* fails to make good and the field is occupied to the virtual exclusion of other forms of the parasite by *Plasmodium vivax* The long term relapse which is characteristic of this parasite not only appears to have enabled it to circumvent what would otherwise be very serious difficulties in maintaining transmission but it also gives to malaria in the temperate malaria zone quite peculiar seasonal and other epidemiological features

Subtropical zone malaria and tropical zone malaria differ from each other largely because in the latter long periods of extremely low humidity lead to decreased human immunity so that this zone is apt to be the site of those vast epidemics which hitherto in northern India have literally controlled the population These epidemics follow abnormally heavy rainfall and are terminated by the onset of a cold season Equatorial zone malaria has its own form of epidemic which as in the recent Ceylon epidemic follows upon drought and not upon heavy rainfall, and possesses features due to the fact that there is no cold season to cut short its course

All these interesting differences are very clearly set out by Colonel Gill who proceeding from the normal to the abnormal has been in the position to make a very valuable contribution to our knowledge of the causes and mechanism of epidemics of malaria The book is one which all malariologists should read S R C

Sponges

Die Rohstoffe des Tierreichs
Herausgegeben von Ferdinand Pax und Walther Arndt Lieferung 13 Kapitel 9 Schwamme Von W Arndt Pp 1577–2000 (Berlin Gebruder Borntraeger 1937) 45 gold marks

THIS is a new part of an encyclopædic work little known as yet in Great Britain which deals well and thoroughly with the commercial side of natural history There is much worth knowing about beast and bird beyond the ken of even the most learned zoologist The trapper, the fur trader and the plumassier the sponge merchant and the dealer in shells the pearl fisher and the ivory trader the druggist with his fats and waxes glues isinglass musk civet ambergris and galls all these not to speak of the men in Leadenhall Market or Billingsgate are highly skilled naturalists in their own peculiar way and have a fine field of learning and observation of their own

The volume before us consisting of more than four hundred pages is an extremely interesting account of the sponge fishery and the sponge market of the many sorts of sponges known to the trade, their use and value their place and mode of capture and all the trade statistics of this world wide industry

No man knows when sponges were first used They were a household word in Homer s time, and Ulysses called for water and a sponge to wash down the tables and chairs after a certain sad scene in the palace The very name is far older than Greek and harks back to that ancient *lingua franca* of the Levantine fishermen to which *tunny* and *pinna* and the *seine* net belong Oppian gives a picturesque account—it might be a modern one—of the sponge diver with a lump of lead in one hand and his crooked knife in the other and a mouthful of oil to smooth the sea and let the sunlight through From classical antiquity the book passes on to the trade routes of the Middle Ages and the old Italian apothecaries shops—and so at last to the sponge trade of the present day We are shown the fine Turkey cup or Levantine sponges the African Zimoccas the West Indian grass sponges and wire sponges the great elephants ears from the Philippines and many more and still we are only a little way from the beginning of this interesting and useful book

Complex Osmosis

Lectures on Osmosis
By Dr F A H Schreinemakers Pp xi + 266 (The Hague G Naeff, 1938) 8 50 gldrs

PROF SCHREINEMAKERS has been engaged since 1924 in studies in osmotic phenomena which have hitherto only been available in Leyden dissertations and the publications of the Amsterdam Academy of Science In this book he gives a collected account in English of his researches which will be of great interest to those who are concerned with the transport of material in animal and vegetable tissues

The fundamental equations of osmotic equilibrium were laid down by Gibbs, and provided at one time a valuable means of investigation of the properties of solutions, which has been superseded to a great extent by more convenient methods owing to the difficulty of preparing ideally semi-permeable membranes But ideal membranes rarely occur in Nature and, especially in complex solutions, a baffling variety of phenomena is encountered

This book is not concerned with the properties of solutions which determine the osmotic equilibrium but with the effect of the membrane on the *path* by which osmotic equilibrium is approached and the different types of behaviour which may be encountered in numerous different circumstances Thus although osmotic flow must always proceed on the whole towards thermodynamic equilibrium, when a membrane is permeable to two or more of the substances present it may happen that one substance is carried by another against its natural direction of osmotic flow, giving rise to apparent negative osmosis Again a membrane may be permeable to two substances in certain proportions , or only within a certain range of concentration In connexion with the latter, Prof Schreinemakers discusses some ingenious models of mechanisms by which this may be effected (checking membranes)

Although illustrative examples are given of many of the phenomena, with membranes of pig's bladder, 'Cellophane' and parchment, the book is not primarily concerned with phenomenological aspects of the behaviour of membranes It is to be regarded as the grammar of the subject, where all possible types of behaviour are tabulated and codified, thus providing a framework to which observed phenomena can be referred It is not easy to read, and the severe form of the presentation may repel some but its study by all students of membrane phenomena would be amply repaid

Finally we may note a point which is not generally known namely, that in the triangular representation of ternary systems the usual equilateral triangle may be replaced by a right angled triangle on ordinary graph paper which has similar properties J A V Butler

Northeastern American Marine Algæ

Marine Algæ of the Northeastern Coast of North America
By W R Taylor (University of Michigan Studies Scientific Series, Vol 13) Pp ix + 427 + 60 plates (Ann Arbor University of Michigan Press, 1937) 5 dollars

RECENT handbooks dealing with the marine algæ of specific localities are few in number and no systematic account of these plants has come from North America since Farlow wrote his handbook of New England algæ more than fifty years ago Prof W R Taylor's volume describes the algæ from the Virginia capes to the arctic islands and Hudson Bay, and incorporates an incomplete manuscript left unpublished on the death of F S Collins in 1920 Collins's published works and especially his volume on the green algæ of North America have shown the breadth of his knowledge and experience and it will be therefore with especial satisfaction that algologists will learn of the incorporation of his unpublished work in the present volume Prof Taylor makes it clear, however, that the book must not be regarded merely as a revision of Collins's manuscript, and points out the wider geographical range with which it deals

Recent research on the marine algæ has been considerable and many new facts relative to their life-histories have been revealed, especially perhaps in the Phæophyceæ, where the mode of over wintering of the so called 'summer annuals' is gradually being discovered In the Rhodophyceæ, too, our knowledge of life histories has increased and new light has been shed on the life cycles of aberrant forms Such additions have their bearing on classification, and it is therefore obvious that Prof Taylor, though using the facts incorporated in the older manuscript, was forced, in the light of recent work, to make major changes in classification and in the description of some of the life histories

In the present volume, some 530 species and varieties are described and as many of them are also present in Britain, the book will be of value to algologists on this side of the Atlantic as well as to those who are working on the particular area with which the author deals Most of the common species have been redescribed from American material and data secured from the literature incorporated especially in regard to life cycles and the anatomy of reproductive organs In addition references are given to two exsiccatæ Algæ Exsiccatæ Americæ Borealis by Farlow Anderson and Eaton and Phycotheca Boreali Americana by Collins Holden and Setchell References are also made to relevant books and papers to synonomy and to illustrations It is of especial value to students of the subject to have references to morphological papers included in a systematic study of this kind and this greatly enhances the general value of the work

The author begins his volume with lists showing the geographical distribution of the commoner algæ and a brief account of algal habitats and floristic areas together with careful notes on the collection and preservation of specimens A brief historical survey follows in which the history of the study of American algæ is given This is followed by a classified list which will be of especial use as a check list to workers in other regions Keys for orders, families, genera and species are incorporated in the descriptive catalogue, and each species is described briefly the localities given and references cited

In the Phæophyceæ the classification adopted appears to be that suggested by Kylin in 1934 ("Zur Kenntnis der Entwicklungsgeschichte einiger Phæophyceen ' *Lunds Univ Arsskr* n f Avd , 2, 30 (9)) It is noteworthy that there is a complete absence of any members of the Cutleriales, Dictyotales and Sporochnales in the region described The classification puts *Acrothrix*, *Arthrocladia*, and *Desmarestia* into the Desmarestiales, thus removing *Desmarestia* from the

Laminariales where its brief sojourn on account of the possession of a microscopic gametophyte seemed peculiarly unsuitable on morphological grounds

In the red algæ recent work has been included and the so called parasites *Actinococcus subcutaneous* and *A agregatus* are included in the life histories of *Phyllophora Brodaei and Gymnogongrus Griffithsiæ* of which they are now known to form a part

With further reference to anomalous forms and in view of the work of Svedelius on the genus (The apomeiotic tetrad division in *Lomentaria rosea* in comparison with the normal development in *L clavellosa* *Sym Bot Upsal* II 2) it is interesting to note that *Lomentaria orcadensis* (Harvey) Collins is recorded only with tetraspores The investigation of the nuclear condition of this plant would be of especial interest

The book is illustrated by sixty plates drawn by Chin Chih Jao whose skill and algological knowledge have combined to produce illustrations of a very high order The drawings of external morphology are especially delightful and those drawn at high magnification combine accuracy of interpretation with beauty of line It is perhaps less convenient to have the illustrations at the end rather than inserted in the text but doubtless there were technical reasons for the decision For the benefit of those who are not very familiar with the region a map showing the general distribution of the algæ would have been helpful and could easily have been constructed from the data given

An extensive bibliography completes a volume that will be welcomed by algologists as a systematic handbook of a new and particularly pleasing kind L N

Statistical Theory

Simplified Statistics
By Leonard J Holman Pp xii + 142 (London Sir Isaac Pitman and Sons Ltd 1938) 3*s* 6*d* net

IN recent years it has been widely recognized that a knowledge of statistical theory is not only important in the sciences but is also of great usefulness in many fields of business and commerce Courses on statistics are now given in various commercial colleges and the subject is finding a recognized place in any well balanced commercial curriculum These developments have already called forth a number of suitable text books in which the subject is approached in a simpler and more practical way than in the earlier books where statistics was treated for the most part as a branch of mathematics

The regular student having been thus catered for the question arises whether it is possible to present statistical theory to the general public For this a still simpler and more attractive treatment is needed and it is such a presentation that the author has provided in this volume In his preface he enumerates the classes of readers for whom he has written Some people are in the habit of using statistical formulæ without having the least idea how the formulæ have been derived There are others who at one time made an effort to study statistical theory but coming up against a mass of algebraic formulæ abandoned the attempt But the general public is for the most part unaware that there is a theory of statistics and understands by the word statistics nothing but the lists of figures in official records such as census and trade returns Such readers if they have an aptitude for mathematics and are interested in the derivation of formulæ will in this book learn of the underlying laws and of the connexion of these with mathematical probability The examples are well chosen from everyday life the author not only considers the monthly fluctuation in the sales of a commodity but also discusses in detail how one would set about verifying such propositions as Smoking during youth inhibits growth and Brunettes are more excitable than blondes

In places the author has not succeeded in smoothing the reader s path At the very beginning of the book the reader is confronted with a diagram consisting of three large rectangles and a few smaller rectangles The diagram looks like the floor plan of a house and the beginner may be astonished to find that without warning the rectangles are referred to as a curve in fact a bell shaped curve The author has overlooked the fact that to the inexperienced eye rectangles do not look like a curve On the whole however the author has taken great trouble to make each step clear and sometimes to cheer the reader on his way with jocularity in the style of a news reel commentator The nature of statistical theory is such that the non mathematical reader can scarcely expect to follow the details of the argument without unusual perseverance but to any who wish to try their strength the book can be sincerely recommended R W G

Die Sedimente des äquatorialen Atlantischen Ozeans

Lief 2 C Zusammenstellung der Untersuchungsergebnisse nach Stationen geordnet, D Auswertung der Ergebnisse Von Prof Dr Carl W Correns, mit Beiträgen von V Leinz und O E Radczewski (Wissenschaftliche Ergebnisse der deutschen Atlantischen Expedition auf dem Forschungs und Vermessungsschiff *Meteor* 1925–1927, herausgegeben im Auftrage der Notgemeinschaft der deutschen Wissenschaft von Prof Dr Albert Defant, Band 3, Teil 3) Pp xii+135–298 (Berlin Walter de Gruyter und Co 1937) 20 gold marks

IN this report, Dr Correns gives the result of the mechanical mineralogical chemical and microscopic examination of more than a hundred specimens of the bottom deposits from the equatorial parts of the Atlantic Ocean The larger number of these were cores obtained with a sampler of the Ekman type, and the longest measured 95 cm When the core consisted of more than one part each part was examined separately, and in nearly every case it was possible to assign it to its period, glacial, interglacial or post glacial An interesting result of this is that it is shown that in glacial times fine sand blew seawards from northern Africa as it does now from the Sahara

The mineral components of the various types of deposit are found to be much more uniform than was supposed previously, the minerals occurring in blue mud Globerigina ooze and red clay are strikingly similar Special attention was paid to the content of calcium carbonate, which is of great interest in view of Wattenberg's investigations into the conditions under which it is dissolved by the bottom water In the deep sea it is chiefly foraminiferous and W Schott has found that the sieve fraction No 2, with a particle radius of 1 0–0 1 mm consists almost entirely of foraminifera He uses this weight to calculate the foraminifera number of the deposit

Dr Correns sees in the deep sea deposits of the equatorial Atlantic Ocean a transition from blue mud with rapid sedimentation of the mineral components, by way of the calcareous clays and Globerigina ooze to the red clay, in which the finest minerals fall slowly to the bottom while the calcium carbonate is redissolved

Fortschritte der Paläontologie

Herausgegeben von O H Schwindewolf Band 1 Bericht uber die Jahre 1935 und 1936 Pp viii+374 (Berlin Gebrüder Borntraeger, 1937) 29 60 gold marks

THIS new periodical is intended to form a biennial review of the progress of palæontology It was planned with the idea that it should serve to keep up to date the "Handbuch der Paläozoologie", but the publication of that work was delayed and the first part has only recently appeared

The arrangement of the volume is similar to that of the *Palaeontologisches Zentralblatt* It begins with sections on text books, phylogeny, palæogeography, zoogeography and other general subjects, followed by sections on different groups of fossils, each written by someone with a special knowledge of the group and concluded with a select bibliography Each section aims at giving a summary of the more important work published in the years 1935 and 1936 With so many authors there must necessarily be some want of uniformity in both the character and the amount of information given, moreover, the quality and amount of research done must vary in different groups so that some sections of the volume lend themselves to more interesting treatment than others

The periodical should be of great value to advanced students and to specialists who wish to keep in touch with the work which is being done in other fields of palæontology

Heredity

By Prof A Franklin Shull (McGraw Hill Publications in the *Zoological Sciences*) Third edition Pp xvii+442+1 plate (New York and London McGraw Hill Book Co Inc 1938) 21*s*

THIS book has been largely rewritten in the present edition Its contents are still concerned mainly with the genetics of cultivated plants domesticated animals and man The human side has been considerably extended, and the order of the chapters rearranged Chapters are included on eugenics, population race problems and immigration

The book is intended as an introductory statement on genetics for first year students in American universities who have had no previous training in biology and are taking up the subject from the general cultural point of view It contains much that would be of interest to the general reader and should help the student to orientate himself regarding the bearing of genetics on human affairs The quantitative or biometric side of genetics is treated in an appendix of twelve pages This is followed by a series of 660 questions and problems based on the text, a list of literature and an index No typographical errors were noticed but Fig 34 A from another text book gives a misleading conception of the relative size of the parts in a flower bud

La Vie des mouches et des moustiques

Par E Séguy (Bibliothèque Juventa) Pp 254+12 plates (Paris Librairie Delegrave, 1938) 16 francs

M. SÉGUY the author of this manual, is a well known student and writer on the Diptera The book therefore is authoritative although essentially non technical Written in a clear style, it conveys to the general reader the latest essential information regarding flies and mosquitoes, their habits and more especially their relations with man The title of the book does not really convey the idea of its main purpose which is to disseminate knowledge of the great economic importance of this order of insects It deals in special with the relations of Diptera to human and animal disease, whether it be caused by the larvæ (myiasis) or brought about by the adult flies as vectors The book is illustrated by numerous figures combined into 12 plates which are drawn by the author It deserves a good reception, not only in France, but in other lands also

Swedenborg's Treatise on Copper

THE circumstances in which a translation of Swedenborg s historic Treatise on Copper ' has become available to the public are indicated in a preface to the edition recently published* written by Mr Fullman editor and information officer of the British Non Ferrous Metals Research Association He writes

"In 1734 Emanuel Swedenborg, the Swedish Scientist, Philosopher and Mystic, published the three volumes of his Latin Treatise 'Opera Philosophica et Mineralia' The first volume contains a mechanical and geometrical theory of the origin of things a translation was published by the Rev Augustus Clissold under the title 'The Principia or the First Principles of Natural Things', (London 1846 2 volumes) The second volume deals with iron and steel and has been translated into French and Swedish a long review of the Swedish translation by Harald Carlborg appeared in The New Philosophy', April 1926, Vol 29, No 2, pp 33–59 The third volume is concerned with copper it is commonly known as The Treatise on Copper, or 'de Cupro', since the Latin title commences 'Regnum Subterraneum sive Minerale de Cupro et Orichalco' "

Some years ago Mr Fullman had occasion to check various references to the Treatise on Copper and not finding any version of the book other than the original Latin called on the Rev J R Presland librarian of the Swedenborg Society at Swedenborg House to see if he could assist him From him he learned that no translation of the "Treatise" had been published but that the Society had a manuscript translation in its strong room, and also that Mr L P Ford had approached Mr A H Searle with a view to the translation of the original Latin and that the work was done at Mr Ford s expense in 1901 He offered the translation to the Council (then Committee) of the Swedenborg Society "on the condition of its undertaking to publish the work" This offer the Committee found itself unable to accept At a meeting, held a year later a request was received from Mr Ford ' to preserve the English translation of Swedenborg's treatise on Copper by depositing it in their strong room" This request the Committee granted and the manuscript was shortly afterwards placed in the strong room at No 1 Bloomsbury Street, London from which it was transferred to Swedenborg House, Hart Street W C 1 when the Society moved there in 1925

The translator Authur Hodson Searle was born in 1839 and died in 1914 When he was about four years old, he suffered an illness which deprived him completely of his hearing and consequently, for a time, of speech He was taught the finger alphabet and lip reading and thus learned to converse, although in a somewhat muffled voice In spite of these physical disabilities he became an excellent Hebrew and Latin scholar He was not a metallurgist being in fact occupied as an artist in reproducing for the engraver plates of conchological specimens All in all as Mr Fullman writes, his preparation of this translation is a remarkable achievement and no reader of it can fail to be impressed by its quality '

The British Non Ferrous Metals Research Association has recently reproduced the translation in mimeograph form in three volumes and the present reproduction makes this work which is of great interest to metallurgists and others readily accessible at a reasonable figure

Swedenborg divided his ' Treatise" into three parts The first which constitutes the great bulk of the work and is the most important deals with the methods of smelting copper from its ores and the refining of copper as produced in Sweden Norway Russia, England, Spain, Hungary, Germany Austria and elsewhere with notes on the same subject from treatises by various authors The latter part of this volume contains an account of methods used for the separation of silver from copper and a discussion of brass and processes for its production The second part commences with an account of the nature of various copper ores and their occurrence throughout the world, and then deals with the assaying of copper ore, including assaying for silver The third and last part deals with miscellaneous matters including the production of various compounds of copper the specific gravity of the metal and its increase of weight on oxidation

Pride of place in the first part is given to an account of the method of roasting, smelting and refining of Fahlun ore This was one of the greatest copper mines in the world The author states that, at the time of publication of his book, the great mine was still unexhausted though having been continuously worked for a period of a thousand years At the height of its fame it yielded 60,000 cwt of copper yearly, so that, to use his words, "All its foundations, doors, grottoes, walls, porticoes, halls and columns were thrown open to their fullest extent, the ore glittering on all sides with a ruddy glow and almost blinding the eyes with rays of golden colour, so that the guests now coming from Fahlun seemed to be, as it were, introduced into the presence of Venus herself, sitting as a bride or newly wedded wife in her most splendid decorated bridal chamber, ready to receive and welcome them most joyfully"

---

* British Non Ferrous Metals Research Association Miscellaneous Publication No 333 Swedenborg's Treatise on Copper (Opera Philosophica et Mineralia Vol 3) Translated into English by Arthur Hodson Searle Section 1 Being Chapters I–XIX of Part I of Original Pp xviii+180 Section 2 Being Chapters XX XLIX of Part I of Original Pp iii+181 348 Section 3 Being Chapters L–LIII of Part 1 Part 2 (Chapters I IV) and Part 3 (Chapters I–XII) of Original, with Index Pp iv+349–536 (London British Non Ferrous Metals Research Association 1938) 25s to Members 15s

The extraction of copper from its ores, mainly sulphide ores, containing iron, usually with some arsenic and antimony, was a long and laborious process Briefly, it was as follows First there was a calcination to drive off volatiles wood fuel being used This was followed by fusion and smelting, in which the fuel was crushed coal, the air being blown in from a blast pipe about three inches in diameter In this way a copper 'stone' was produced and collected in the fore hearth, which was tapped every two hours This stone was of an intense blood red colour and flowed very slowly Then followed a second calcination which consisted of six successive treatments in a 'burning fire' The gradual removal of the volatiles took place, with accordingly an enrichment of copper This calcination lasted about five weeks Then came a second smelting, which occupied a further week, in which further quantities of iron were slagged off, and the cupreous product was tapped from time to time This was known as coarse or black copper These furnaces were situated within a mile of the mine and there were about a hundred and thirty of them Next followed the refining of the coarse copper at Afwedstad in Sweden and the final stage consisted in the smelting of this so that it could be beaten out into laminæ or plates The total period required was between seven and eight weeks and the maximum annual production was about 2,000 tons, corresponding to a weekly output of not more than 40 tons When it is considered that the daily production of a modern copper works is of the order of 300 tons of refined metal, it will be realized that considerable advances have been made in the smelting and refining of copper in the last two hundred years

The British Non Ferrous Metals Research Association is to be commended for its public spirit in rendering available a treatise which gives so much information about the metallurgy of copper in the late seventeenth and early eighteenth centuries

Oceanography and the Fluctuations in the Abundance of Marine Animals*

By Dr. Stanley Kemp, F.R.S.

It is interesting to note that the observations we have of salinity and temperature cannot be correlated with the biological data For many years past, Dr H W Harvey has followed the temperature and salinity changes at the western end of the Channel, and during the period since 1924 he has found that the most conspicuous movements were large incursions of low salinity water in May 1928 and in March and April 1936, while in 1932, 1933 and 1934 (especially in 1933) patches of water with unusually high salinity moved eastwards up the Channel So far as can be seen, these movements show no correspondence with the marked biological changes which have occurred it is in the phosphate data only that a correlation can be found

In the year 1921 there was an exceptional influx of Atlantic water, which filled the Channel and flooded into the North Sea Salinity and temperature were much above normal and numbers of unusual planktonic organisms of Atlantic origin were found in the North Sea. Recent experience at Plymouth might lead one to think that such an influx as this would bring benefit to the herring fisheries, but actually it was just the reverse, for at Plymouth and in the North Sea at Lowestoft Yarmouth, Grimsby and North Shields, the herring fishery was much below normal

It thus appears that incursions of Atlantic water into the Channel may bring advantage to the biology of the area or may be detrimental, that no obvious connexion between the biological data and temperature and salinity is noticeable, and that so far as we can at present see, the only correlation that can be established is with phosphate The explanation lies, I believe in our very considerable ignorance of the constitution and origin of the water masses which from time to time enter the Channel

There is evidently more than one way in which an influx of Atlantic water may be advantageous It may, in the first place, bring water with a high content of phosphate and other nutrient salts which will eventually yield an abundant plankton Or, secondly, though deficient in phosphate, it

---

(Continued from p. 779)

may bring in large quantities of phytoplankton or zooplankton, the product of a former richness in phosphate This plankton will afford an immediate food supply for larval fish and other animals, and when it dies down the phosphate will be regenerated and will serve for further plankton production in the future

It is thus what we may call the biological condition of the water that is of importance and this no doubt is to some extent determined by the season of the year At times in summer the surface water may be largely devoid of both plankton and phosphate and an influx of such water, even though its high salinity may indicate an oceanic origin, will bring no improvement to biological conditions and may indeed be harmful In winter when the thermocline has broken down and surface phosphate has been renewed by convection and by stormy weather an influx may prove of advantage But it is perhaps more probable that upwelled water rich in the nutrient salts which are always to be found in the lower layers of the ocean is the potent source of surface enrichment, and of the conditions in which such upwelling occurs we are very largely ignorant We lack the necessary data and can merely speculate on what may be happening from analogy with what is known in other areas

I have dwelt at some length on these events in the Plymouth area because they afford a good example of a long period fluctuation and illustrate the way in which observations drawn from widely different lines of inquiry are linked together From other sources also there is good evidence of long period fluctuations in fisheries, and though the hydrographical changes to which they may ultimately be traced are not, as it appears, the same as in the Channel, they show that major alterations extending over a long term of years are by no means unusual

In 1925 the Norwegians discovered great numbers of cod on the banks surrounding Bear Island, and ever since that year, except in 1929 when ice interfered with the operations, the fishery has been maintained, many trawlers visiting the banks annually to take toll of their wealth Iverson, from whose paper my information on this fishery is derived, states that there was a former occasion when cod were plentiful in this area That was from 1873 until 1882 Between 1883 and the time when the present fishery began, the grounds were examined on a number of occasions, but very few cod were found and the results were unprofitable It was so in 1924, the year which preceded the present period of abundance

Another instance is afforded by the cod fishery in West Greenland At certain times large concentrations of cod appear on this coast and spread as far north as Disko Bay, affording a profitable fishery, but after a term of years their numbers suddenly decline and a protracted period of scarcity follows In 1917 cod were found in West Greenland in great abundance and the fishery on this coast has been maintained up to the present day Prior to that, as Jensen and Hansen have shown, the grounds were tested on a number of occasions without finding stocks of cod in marketable quantity, but early records indicate that there were at least two periods in 1820 and in 1845–49 when cod were present in great numbers

To these two instances of large scale changes in the fish population in northern waters many others could be added and all are apparently due to the same cause—to the fact that in recent years the entire area from Greenland to Bear Island has become appreciably warmer Berg has collected much information on the effects of this rise in temperature, Saemundsson has given an interesting account of the alterations which have occurred in the fauna of Iceland while Stephen has shown that marked changes have also taken place in the British marine fauna It is clear that an increased sea temperature, probably of the order of 1 0–2 0° C, has allowed various species of fish to extend beyond the normal limits of their distribution, with the result that it has been possible to establish productive fisheries in areas which formerly would not have yielded an adequate return It is evident, I believe, that at some future date conditions will revert to normal, and that a time will come when these lucrative fisheries will cease to exist

A distinction—which I believe to be a real one—can therefore be drawn between two kinds of fluctuations, both of which have a pronounced effect on the marine fauna Normal annual fluctuations are a constant feature They form the basis of fishery prediction, and our information, such as it is, is that their incidence is restricted a fishery for a certain species in a particular place will be affected, while other species in the same place, or the same species in another place will be unaffected It is to be assumed that the causes of such annual fluctuations, though of these we know but little, are also restricted both in space and in time

In contrast are what I have called long period fluctuations, which extend over a term of years and involve much larger areas Such fluctuations as these are due to a widespread change in one or more of the hydrographic factors in the environment, and large numbers of species, if not all, are affected simultaneously or within a short period. Long period fluctuations may mask the effects of the annual fluctuations and at times they will render fishery prediction unreliable.

Research in the Atlantic

Long period fluctuations may be brought about in entirely different ways In the Channel, as it appears, the change can be traced to a deficiency in phosphate, while in more northerly areas it is due to an increase in sea temperature But, though there is this wide difference the two sets of circumstances have this in common, that they originate in the open Atlantic, at the edge of the continental slope or farther to the west It is here in oceanic waters, that the causes of these large alterations in European fisheries must be sought

It might be thought that a full investigation of the Atlantic drift to which we owe so many advantages, would long since have been undertaken Yet, to the present day, there are many problems which remain unsolved and, as Dr Iselin has recently shown three mutually conflicting theories are extant regarding the circulation of water in the North Atlantic Fortunately there are signs that a period will be set to our ignorance On the American side of the Atlantic, the Woods Hole Oceanographic Institution and the Bermuda Biological Station are collaborating in a study of the Gulf Stream and of the effect of wind velocity and direction on the strength of a current Data recently obtained by the Woods Hole Institution show that the transport of water in the Gulf Stream has varied by as much as 20 per cent in fourteen months, and it may well be that this figure is below the normal range of variation When the observations over the five year period which is contemplated have been carried out, we may hope to know far more than we do at present of the Gulf Stream and its effects on circulation in the North Atlantic

During the present year, a German research ship is making a prolonged investigation of the hydrography of the North Atlantic, and only two months ago research ships from Denmark, Norway and Scotland were co operating with her in studying extensive areas from the Azores to Iceland

From such combined attack we shall learn much, and there is every reason to believe that the main features of the circulation in the North Atlantic will shortly be understood But the work in the eastern Atlantic is only an isolated set of observations, most valuable as a contribution to our knowledge of the general conditions, but affording little help in solving the problem of long period faunistic fluctuations of which I have spoken It is the deviations from the normal which are of paramount importance to the biologist and it is only by repeated observations made over a series of years that they can be detected I believe that the need for systematic oceanographic work in the eastern Atlantic will be more and more acutely felt as time goes on and I feel convinced that it is the only way in which we can ever reach an understanding of the reasons for the large fluctuations in our fisheries

Fisheries Research in the British Empire

There is an urgent need throughout a very large part of the British Empire for greater activity in the scientific administration of the fisheries, for to me at least it is apparent that the lessons which long years of experience have taught us in Great Britain are not generally understood elsewhere

The plain fact is that in the Empire as a whole we are deplorably deficient in fisheries administration To this broad statement there are of course some exceptions By reason of its situation in Europe, the Irish Free State is obviously one of them and it has taken its full share in the progress that has been made during the present century Another exception is Canada, where a vigorous fisheries service, with a competent scientific staff has been at work for many years Newfoundland a country to which fisheries are of predominant importance, not long since suffered a shattering blow in the loss of the whole of its laboratory buildings by fire, but it will recover from this disaster and we may hope that the work which had such a brilliantly successful beginning will shortly be resumed Australia has now made a fresh start after the tragic loss of the *Endeavour*, and has at last taken the wise step of founding a Commonwealth fishery department These are the high lights, and there are one or two colonies, such as the Straits Settlements and Ceylon, which give relief to what is otherwise a very sombre picture

In South Africa with its astonishingly rich fishing grounds and vast length of coast line, the fishery staff is utterly inadequate, and in India, where fisheries research has immense possibilities, there is apparently little hope that proper action will be taken In India fisheries are what is known as a transferred subject that is to say, they have been handed over by the central Government to the provincial administrations The result is that some provinces may have a scientific staff of one, others have none at all, while Madras, which is much the most enterprising and publishes a fisheries bulletin, has three In such conditions fishery work on any adequate scale is clearly out of the question and it is not possible even to begin the acquisition of the fundamental knowledge that is essential to future progress

In almost every problem which touches marine biology it is essential to possess a background of knowledge which can only be acquired by long years of patient study If there is one lesson to be learnt from the history of fisheries research—one that cannot be too heavily stressed—it is that the opportunity of dealing effectively with a fishery problem will generally be lost unless this basic knowledge has been obtained in advance and is ready for application Even in our home waters, which have been examined so long and so closely, our information is not within sight of being complete in almost every branch of fisheries work there are new fields to be explored new methods to be tried and many large gaps in the knowledge we possess But it may at least be said that we have made a beginning In many other parts of the world not even a beginning has yet been made, ignorance is profound and there is no background of knowledge which can be utilized

It is surely time that the importance of such knowledge was recognized and that early steps were taken to lay the foundations of fishery science throughout the Empire

---

International Standard of Musical Pitch

By Dr. G. W. C. Kaye, O.B.E.

THE problem of the international standardization of musical pitch has recently assumed a new prominence in view of the increasing exchange of concert and similar programmes by the various broadcasting organizations in different countries The general question has come up from time to time in the past, though it cannot be said that any substantial measure of unification has ever resulted internationally

The history of musical pitch is one of many standards mainly evolved by some body of standing which at the time was able to impose its will to a greater or less extent on current practice In some countries, indeed, the choice of pitch was, and still is, enforced by legal decree It has long been customary to express musical pitch in terms of the frequency of the note A in the treble clef, and this convention will be observed in what follows

Ellis (*J Roy Soc Arts* 1880) gives us a good notion of the state of affairs which prevailed in the early history of musical pitch It appears that from the fourteenth to the seventeenth century the note A wandered haphazardly over a range of nearly 200 cycles per second (374 to 567) In the eighteenth century the upper limit came down by more than 100, the spread of pitch being from 377 to about 423 During the nineteenth century the range was from about 424 to 494, a progressive rise being evident up to about 1887 reflecting no doubt, as always a striving for increased brilliancy

In Great Britain the London Philharmonic Orchestra was the premier orchestra for many years, and the philharmonic pitch was followed by most other orchestras, being first based in 1826 on a value of 433 for A, and afterwards (nineteen years later) on 455 A conference of physicists at Stuttgart in 1834 adopted 440, while a similar conference of musicians and physicists appointed by the French Government in 1859 established the Diapason Normal which was based on a figure of 435 (largely through the influence of Koenig) the associated temperature of the instruments being taken as 15° C (59° F) This pitch, which was legalized in France and had a fairly wide vogue in Europe, was adopted by the Boston Symphony Orchestra at its foundation in 1883 and was endorsed in 1885 by an international congress at Vienna In 1896, the Philharmonic Society adopted 439 at 68° F (see Hipkins NATURE Aug 31, 1899), while in 1899 an international discussion by the pianoforte trade, which revealed values of A ranging from 435 to 442, also resulted in the adoption of 439 at 20° C (68° F) by the participating makers, a decision which materially assisted in checking the general tendency of pitch to rise Another significant step was the lowering in 1927 by the Army Council of the pitch of British Army bands from 455 to 439 at 68° F

In the United States, while musical pitch was the subject of many vagaries during the last century a figure of 440 is now universal, having been adopted by the American Federation of Musicians in 1918, the Music Industries Chamber of Commerce in 1925, and the American Standards Association in 1936 It may be added that this value is in good accord with the usual British figure, as the temperature in American concert halls is said to be customarily of the order of 70° F

To come to more recent events, a conference was recently held at Broadcasting House under the auspices of the British Standards Institution, with Dr G W C Kaye in the chair The conference was attended by representatives of some thirty musical and other organizations, including the Royal Academy of Music, the Royal College of Music, the Royal College of Organists, the Royal Military School of Music, the Musical Association, the British Broadcasting Corporation, the Old Vic and Sadler's Wells, the National Physical Laboratory and the federations and associations of manufacturers of wind and string instruments and organ and piano builders The meeting had also before it the views of eminent conductors and professors of music After a full discussion, the conference agreed unanimously that the British Standards Institution, as a member of the International Standards Association, should be asked to take action to try to secure an international standard of musical pitch A small committee, which was appointed to draw up definite proposals, has now commenced its labours

It emerged from the above meeting that, pending international agreement, the British Broadcasting Corporation has provisionally adopted a figure of 439 for the treble A It also appeared from radio observations made in Germany that many of the musical performances now broadcast from different countries in Europe are based on a pitch exceeding 435, being on the average about 443

The most recent information available appears to indicate that the accepted figures for A in most countries lie between 435 and 440 cycles per second, although this range is definitely broadened in actual practice On the whole, it would seem that if an international figure were to be adopted, it will probably be at or near 440 The choice of such a figure, which is of course absolute would be the primary duty of an International Conference

The next duty, though a secondary one, would be to deal specifically with the temperature question Many musical instruments, as at present constructed, exhibit appreciable temperature variation of pitch The majority of the stringed instruments present, of course, no difficulty in this respect, and, as regards the piano, its pitch is stated to fall by only about 1 part in 18,000 for 1° F rise in temperature actually, the effects of humidity changes are probably more significant In the case of the wind organ, which presents the major problem, the pitch of the flue-pipes rises about 1 part in 500 for 1° C rise (that is, about 1 in 1,000 per 1° F) for moderate temperature variations In other words, a pitch of 435 at 15° C becomes 439 at 20° C The orchestral wind and reed instruments (flute, oboe, clarinet, etc) are also influenced by the warmth of the breath, fingering, etc , they are said to have, on the average, about half the temperature coefficient of the wind organ

One of the great difficulties with most concert halls is the steady rise of temperature as a concert progresses, so that the pitch of an orchestra may rise by five or more cycles a second during the early stages of a concert It has been observed in Germany that, after the entry of wind instruments which had been kept cold, a sudden shifting of the pitch of an entire orchestra may often result Thus the concert pitch may be subjected to continual fluctuations during the playing Improvement may be effected by warming the instruments before a concert to bring them into a steady condition

The oboe which is often used as an orchestral standard of pitch is demonstrably unsatisfactory for the purpose The piano is clearly better, and a steel tuning fork better still, with a drop in pitch of only about 1 part in 16,000 for 1° F rise in temperature Elinvar forks are even better, with a positive or negative coefficient varying in different samples up to 40 parts in a million Valve oscillators with mica condensers can be readily constructed which have a temperature coefficient of pitch of less than 1 part in 1,000

There are two features which are likely to simplify the temperature question in the future One is the increasing vogue of air conditioning, which will make the temperature control of concert halls more feasible The other is the rapid development of electro acoustical instruments, such as the electric organ, which have no temperature coefficient, and would appear to present an important field of development Incidentally, the values adopted for the treble A in two well known makes of electric organ are 439 and 440 respectively

It is of course appreciated that temperature variation may be especially troublesome under outdoor conditions, which may be extreme in some countries, and it is probably impossible to legislate for such untoward circumstances Something can be done, it is stated, by pre tuning the different instruments, for example, in the case of military bands in tropical countries, by flat pitch tuning of the wind instruments and sharp pitch tuning of the percussion instruments

It is clear, however, that as things are at present, international agreement can only be secured for what may be termed reasonable concert hall conditions and until those conditions are such that the pitches of musical instruments are virtually free from temperature change, the working temperature will normally require to be specified It seems probable from the above that a figure at or near 20° C (68° F) is likely to be acceptable to the majority of nations

The indications are that an international conference on the question of musical pitch may be convened in 1939 It would accordingly be appreciated if those readers of Nature who are interested in the general situation would be good enough to communicate with the Director, British Standards Institution, 28 Victoria Street, London, S W 1.

Science and Engineering in Antiquity

GIBBON, in The Decline and Fall of the Roman Empire", when describing Rome in all its glory, said the city was "filled with amphitheatres, theatres temples porticoes triumphal arches, baths and aqueducts all variously conducive to the health, the devotion, and the pleasures of the meanest citizen ' The aqueducts appealed especially to him and of them he wrote The boldness of the enterprise, the solidity of the execution and the uses to which they were subservient rank the aqueducts among the noblest monuments of Roman genius and power " They evidently make the same appeal to Mr W J E Binnie, who, having taken as the theme for his presidential address to the Institution of Civil Engineers, delivered on November 1 "Science and Engineering in Ancient Times ' devoted many of his remarks to the work of Frontinus on the aqueducts This subject no doubt was also a congenial one, owing to Mr Binnie's own work as a hydraulic engineer

Sextus Julius Frontinus, who was born about A D 35 and died about 106, was a very able and conscientious government servant and for a time was governor of Great Britain When about sixty years of age he was appointed Curator Aquarum' or Commissioner to the Water Supply of Rome, and this led him to write his two books, ' De Aquis Urbis Romæ", an English translation of which was published in 1899, by the distinguished American hydraulic engineer, Clemens Herschel (1842–1930) himself the inventor of the Venturi meter When Frontinus took office there were nine aqueducts carrying water to Rome, and one of them had been in use nearly four hundred years, a longer period than Drake's leat has carried water to Plymouth The total length of the nine aqueducts was 263 miles, about 35½ miles being borne on arches The total capacity as estimated by Herschel was 84 million gallons a day, but the actual quantity supplied did not amount to more than 38 million gallons The Appian aqueduct (313 B C) was sixteen miles long and was almost entirely underground , the Anio Vetus (273 B C) was forty miles long The Marcia was fifty eight miles long, and was constructed about 145 B C The two older aqueducts followed the contour of the ground, but in the Marcia, arches with a total length of six and a half miles carried the aqueduct across the valleys The Claudia, the Julia, fourteen miles, the Virgo, thirteen and a half miles, the Alsietina, twenty nine miles, and the New Anio were erected nearer the age of Frontinus, some of them indeed in his lifetime One portion of the Claudia was a tunnel three miles long

The three earliest aqueducts were constructed of dressed stones about 18 in × 18 in × 42 in set in mortar, but most of the later aqueducts were of concrete and brickwork , the arches being divided into voussoirs by brick courses The waterways were rendered with *opus signinum* made of pottery ground into powder mixed with lime mortar The durability of this lining is shown by old underground tanks and conduits in Alexandria, where the surrounding limestone has been eroded away by water, leaving the lining intact Settling tanks were provided on each aqueduct and water was led into buildings by lead pipes Payment was made according to the diameter of the bronze nozzle or *calix* through which the water flowed

Frontinus was aware that the quantity of water varied with the head, and the length of pipe, but the laws governing the flow of water were unknown By laws existed regarding the water supply, and it fell to the lot of Frontinus to enforce them

In considering the construction of the roads, aqueducts, and tunnels of antiquity a question naturally arises as to what methods were employed in surveying and laying down the plans The answer to this question was given by Mr Binnie earlier in his address when dealing with the writings of Hero of Alexandria

To Hero are attributed a book on ' Pneumatics", three on ' Mechanics ', one on "Catoptrics", and another on the "Dioptra ' The ' Pneumatics" has been published in English, and the other five have been translated by Mr R C S Walters, a member of the Institution of Civil Engineers, and Mr Binnie had had the advantage of perusing his manuscripts In this connexion, it is perhaps worth recalling that in 1921 Mr Walters read a paper to the Newcomen Society entitled, "Greek and Roman Engineering Instruments", and that in 1928 the University of Washington, Seattle, U S A , published Mr E N Stone's pamphlet on "Roman Surveying Instruments" For lengths, the Romans used the *Pertica*, the *Decempeda*, and also the *Hodometer*, or road measurer , for horizontal angles they used the *Groma*, an example of which was unearthed at Pompeii in 1912, while by means of the *Dioptra* they could measure both horizontal and vertical angles The *Dioptra* was the forerunner of our theodolite, and with it, said

Mr Binnie, very accurate levelling could be carried out and it was possible to set out aqueducts with very flat gradients

Besides the writings of Hero and Frontinus, Mr Binnie touched upon the work of the Egyptians and their methods of drilling granite the views of Lucretius on matter, the universe and time, the career of Archimedes, and finally and briefly, the work of that versatile genius Leonardo da Vinci, a review of whose many activities was given by Mr E McCurdy to the Royal Institution on March 19 1920 a full report appearing in NATURE of May 6 and 13 and by Mr J W Lieb in a paper read to the Franklin Institute in 1921

Obituary Notice

Prof Karl Sudhoff

WE regret to announce the death of Karl Sudhoff, the Nestor and doyen of medical historians, which took place at Salzwedel in Saxony on October 8 at the ripe age of eighty four years

Sudhoff was born on November 26, 1853, the son of a theologian and philosopher, at Frankfort on Main, the birthplace of Goethe, who formed the subject of many of his non medical writings He qualified at Erlangen in 1875 with a thesis on a subject—primary multiple carcinoma of the osseous system—which gave no indication of his future activities, and for the next thirty years remained in general practice with a leaning towards gynæcology, first at Bergen near Frankfort and afterwards at Hochdahl near Düsseldorf He soon rose to eminence in his profession, and his financial success enabled him to accumulate a library rich in medico historical works

During this time, Sudhoff won a considerable reputation by his studies on Paracelsus, so that he was elected the first president of the German Society of the History of Medicine, founded in 1901 Four years later he was appointed as the first occupant of the chair of the history of medicine at Leipzig, where he founded an institute for this speciality, and held this post until 1924, being succeeded by his brilliant pupil, Dr Henry E Sigerist, now professor of the history of medicine at Johns Hopkins University

Sudhoff's activities may be considered under three headings (1) his successful career as a medical practitioner, in acknowledgment of which he was created a councillor in 1900, (2) his epoch-making work as a medical historian, (3) his ability as an organizer Sudhoff was an extraordinarily prolific writer, as is shown by the fact that a bibliography of his works and those of his pupils occupied nearly thirty pages of the *Festschrift* dedicated to him in 1924 on the occasion of his seventieth birthday, and more than fifty pages of his *Archiv* published ten years later His chief works, in chronological order, were his studies of Paracelsus, the iatro mathematicians of the fifteenth and sixteenth centuries, the anatomy of the Middle Ages, the history of hygiene, German medical incunabula, Alexandrian medicine, ancient balneology, manuscript plague tracts, the early history of syphilis, the school of Salerno, the surgery of the Middle Ages, the history of dentistry, a survey of the history of medicine, and early writers on paediatrics His minor works included obituaries of medical historians and others, an autobiographical sketch entitled 'Aus meiner Arbeit", and numerous reviews of current literature on the history of medicine In addition to purely medical subjects, he wrote on folk lore, magic, alchemy, astrology and Goethe in relation to the Rhineland

Mention should also be made of his editorial work In 1908 Sudhoff founded the *Archiv fur die Geschichte der Medizin und der Naturwissenschaften*, to which his name became attached in 1929, in 1909 he became editor of *Klassiker der Medizin*, and he was also joint editor of several other medico historical publications

The organizing ability of Sudhoff was shown by his establishment of the Institute for the History of Medicine at Leipzig, which he made a model of its kind, the organization of the Goethe exhibition in 1899 on the occasion of the hundred and fiftieth anniversary of the poet s birth, the active part which he took in the preparation of a historical section in the German exhibition of hygiene at Dresden in 1911, and his activity as dean of the medical faculty at Leipzig in 1922–23

Sudhoff had many friends in Great Britain, to which he paid several visits both before and after the Great War His *Festschrift* was dedicated to him by Sir Clifford Allbutt, and several other British writers contributed to the volume He was elected a corresponding member of the Section of the History of Medicine of the Royal Society of Medicine in 1913 the year of the International Congress of Medicine held in London, when he read a paper at the historical section of the Congress on the origin of syphilis, and thirteen years later he was elected an honorary fellow of the Royal Society of Medicine

J D R

WE regret to announce the following deaths

Sir John Griffith, president of the Institution of Civil Engineers in 1919, on October 21, aged ninety years

Mr George Jennison, formerly owner and principal curator of the Belle Vue Zoological Gardens, Manchester, on October 21, aged sixty six years

Colonel J Clibborn, C I E, formerly principal of the Thomason Engineering College, Rorkee, known for his work in connexion with irrigation in Northern India, on October 31, aged ninety years

News and Views

Geophysical Research at Johannesburg

On October 21, the Bernard Price Institute of Geophysical Research at Johannesburg was opened by General Smuts It is specially fitting that Johannesburg, perhaps the wealthiest and most industrialized city in Africa, the prosperity of which depends so largely on mining, should be the seat of this important new enterprise. The Institute is governed, in finance and administration, by a Board of Control directly responsible to the Council of the Witwatersrand University. The University has been enabled to establish and staff the Institute by gifts from the Carnegie Corporation of New York, and from Dr. Bernard Price, resident director of the Victoria Falls and Transvaal Power Company. Dr. Price's deep interest in the work and success of the Institute is shown also in his chairmanship of the Board of Control. The Institute is under the direction of Prof. B F. J Schonland, who as Carnegie-Price professor of geophysics gives post-graduate teaching in the University. At present, the Institute also has on its staff three scientific assistants

The Institute building, situated in the University grounds, has about 6,000 sq. ft enclosed floor space, on two floors; the first story extends only over about half the ground floor, so that there is a large roof terrace over which the first floor building can be extended later if necessary. In addition to the director's office, the library, workshop, store room, dark room and so on, the building contains a seismograph room, an oscillograph room, and five research rooms, in which are incorporated many special features appropriate to the needs of a geophysical research institute. There is also a guest room for the use of overseas visitors who may be co-operating in the Institute's research programme. The present programme of the Institute includes atmospheric electricity (a subject in which Prof. Schonland has already made outstanding contributions to knowledge, and which is of special local importance in view of the severity and prevalence of thunderstorms there), seismology, the study of the magnetic properties of the rocks of the Witwatersrand, and the behaviour of rocks under pressure. Radio studies are also being planned

Institute of Ornithology at Oxford

The statute relating to the proposed Edward Grey Institute of Field Ornithology was brought before Congregation at Oxford this week. Accommodation and funds for the Institute will be provided by the University. There will be a salaried director. The committee of management, although mainly of University members, will have representatives of the British Ornithologists' Union, the Oxford Ornithological Society and the British Trust for Ornithology. The business of the Institute will be to carry out research on problems of ornithology, especially on the numbers, distribution, movements, habits and economic status of British birds and to publish the results obtained It is evident that activity will be concentrated on field work and will begin by extending that done by the Oxford Ornithological Society. The Society has recently made a count of all species over small areas like Bagley Wood and of the waterfowl on the lake at Blenheim. It has also made surveys of a single species over a wider area as, for example, the count of all the rookeries in an area of more than nine hundred square miles around Oxford.

International Committee on Intellectual Co-operation

The report by Prof. G. de Reynold on the work of the twentieth plenary session of the International Committee on Intellectual Co-operation of the League of Nations (Geneva. League of Nations. London: George Allen and Unwin, Ltd C 253.M.150 1938.XII) indicates the services to intellectual life which this organization is rendering both directly and indirectly. Its influence on the teaching of the principles and facts of international co-operation, the revision of school text-books, the investigation of unemployment among university graduates, its studies on the rights of the scientific worker and the inventor and on the contract of publication, the International Studies Conference and the agreement with the International Council of Scientific Unions are briefly indicated by Prof. de Reynold, as well as its relations with the International Labour Office and the International Museums Office. Prof. de Reynold stresses the importance of the National Committees of Intellectual Co-operation and of the efforts of the organization to keep in touch with and respect al forms of culture, and of utilizing the most modern means of disseminating information. Resolutions adopted by the Committee at its meeting on July 16 are included, and among the appendixes are reports of the Advisory Committee on the teaching of the principles and facts of international co-operation, on the teaching of modern languages as a means of promoting mutual understanding between nations; of the Acting Secretary-General of the Rome International Institute for the Unification of Private Law on the work of the Institute in the field of intellectual rights and of the Advisory Committee on Professional Workers.

A further appendix gives extracts from the general report of the director of the International Institute of Intellectual Co-operation to the International Committee and to the Governing Body. In these extracts, reference is made to obstacles to intellectual life, including the questions of student exchange, libraries, archives, etc., the scientific study of international relations as developed by the International Studies Conference, including a note on the Prague Conference on the university teaching of international relations. Other matters dealt with relate to the use of broadcasting for disseminating information on international problems of the day, whether by documentary talks, round table broadcasts or international bibliographic information The use of the same means for disseminating information on the progress of the sciences and on developments in literature and the arts is also discussed, and for planning and sponsoring such programmes the collaboration of leading scientific institutions in different countries should be solicited The organization of a central international information office is also proposed, which with regard to scientific information would be in contact with scientific institutions and scientific workers in different countries, and at regular intervals would provide the programme committees with communiqués on recent discoveries and memoranda on new developments A resolution adopted by the Congress of the International Federation of Associations of Inventors and Industrial Artists recommends that the author of a scientific discovery or invention should not be deprived of his rights because he has himself divulged it in a scientific paper submitted to a learned society or published it in a scientific journal The resolution also urges an international agreement which in all countries would entitle the author of a scientific discovery or invention to claim a royalty from persons or enterprises utilizing the discovery or invention for industrial purposes

The School as a Cultural Centre

A RECENTLY issued bulletin of the United States Office of Education, The School Building Situation and Needs" by the official senior specialist in school building problems, emphasizes the view that the State schools, both primary and secondary, must provide, not only for the education of pupils enrolled in ordinary course as at present but also for cultural needs of other members of the community, notably adolescents who have left school but are not at work and adults needing re education in new lines of work made necessary by industrial changes and for recreation during leisure time It is clear, says the report, that technological advances and the resulting decrease in the number of workers required in industry are going to make it necessary for the public schools to provide either full time or part time education and recreational opportunities for a large proportion of boys and girls, between eighteen and twenty one years of age, who are neither in school nor at work School buildings must be equipped for this purpose A similar expansion of the purposes of school buildings was advocated in two addresses to Section L (Educational Sciences) of the British Association meeting in August at Cambridge by Mr W G Newton and Mr S E Unwin, county architect, Cambridge The former included in his summary of to-day's requirements to be interpreted in the school architect's building forms ' importance of the parent and the use of the school as a cultural centre", while the latter declared that "the school of the future will only be starting its work with child education, it will be a meeting place for people of all ages", " for adult activities, even if only for evening classes and adult lectures, a common room where the People can meet for discussion or friendly conversation, with facilities for light refreshment, will be necessary '

Industrial Arts and Education

THE report of a Committee appointed by the Commissioner of Education to consider the Interpretation of Industrial Arts in American Schools has been published as Bulletin No 34, 1937, by the United States Department of the Interior (Washington, D C Gov Printing Office, 15 cents) The report is primarily concerned with the way in which the study of industrial arts can contribute to a programme of education for a society which is fundamentally industrial, and the significance of such study in providing a background for education for citizenship, apart from its value in stimulating the development of creative and artistic abilities, is stressed The position of industrial arts in the elementary school, the junior high school, the senior high school, in adult education and in higher education is discussed in separate chapters of the report, and particularly in the senior high school, the contribution of industrial arts to vocational training is emphasized as well as its value in safety education In the broadest sense, safety education in the sense of providing every citizen with an adequate scientific or technical background for the life he or she is called upon to live in this present age is one of our greatest needs, and the report would be worth while if only for the terse but illuminating way in which it indicates opportunities which are at present often missed

Utilization of British Hardwoods

MR W A ROBERTSON, director of the Forest Products Laboratory at Princes Risborough, discussed the utilization of British hardwoods in a paper read before the Department of Forestry of Section K (Botany) at the recent meeting at Cambridge of the British Association. The author dealt with some of the more economic species such as oak, beech, ash, birch, sycamore, alder and poplar In discussing the more valuable hardwoods, oak, beech, ash, etc, Mr Robertson pointed to the fact well known to the scientific forester that the poorness of the British present-day timber is due to faulty sylviculture—a position which will not be rectified in Great Britain until recognition by owners of woods is given to the fact that they require just as careful and scientific attention throughout the life of the crop as agriculture Clean grown timber of any type can only be produced by good sylviculture, in which is included the essential item of correct thinning at specified periods The coming of plywood has opened new modes of utilization of large-sized hardwoods, since British timber of these species is every whit as good as the foreign Yet, as Mr Robertson says, the problem of the disposal of thinnings and cordwood still remains a difficulty

Long Ashton Research Station

RECENT developments in fruit products research are described in the Long Ashton Research Station report for 1937 Since 1932 a comprehensive study has been made of the possibilities of utilizing surplus and low grade fruits, both syrups and wines being investigated In 1934, fruit squashes were included in the programme, and with such success that in the following year production employing the Long Ashton methods was extended to the commercial scale Even greater success has attended the researches on fruit syrups The growing popularity of milk bars has resulted in a demand for various syrups as constituents of milk shakes For the last two years the Research Station has worked in close collaboration with a local firm producing these commodities and syrups are now being sold on the large scale under the National Mark Scheme A still more recent development has been the use of these syrups for aerated beverages, the high ascorbic acid content of the juices being an important feature in their favour Wines made from English fruits have attractive characters and are of full alcoholic strength, but they are relatively expensive, and development on the commercial scale is not expected to be so rapid as in the case of the syrups

Seismological Work at Stuttgart

A VERY valuable addition to seismological data and an interesting addition to earthquake literature appears in the report of the Stuttgart Seismological Station for 1936, edited by Dr W Hiller which has recently been received The station is equipped with three Galitzin Wilip seismographs orientated to record N S , E W and vertical movement, two Mainka seismographs of mass 450 kgm to read N S and E W vibrations two vertical Wiechert instruments of mass 80 kgm and 1,320 kgm respectively, and one trifilar gravimeter The report gives the readings of seismograms obtained with these instruments, including the phase, time of arrival amplitude in the three components and remarks chiefly concerning the position of the epicentre of the shock which caused the record At the end of the report are 15 pages of detailed study of earthquakes with epicentres in the neighbourhood of the station, including two sketch maps—one concerning the Bodensee earthquake of March 15 1936, and one of the earthquake of April 19 1936

Public Service Occupations

A BULLETIN entitled Training for the Public Service Occupations issued by the Office of Education, Department of the Interior, United States of America (Vocational Education Bulletin, No 192 20 cents) reviews the work already carried out in training for public service occupations below the university level The Bulletin is concerned with the manual aspects of the public services rather than with the administrative side, and it is intended to interpret the provisions of the George Deen Act as they relate to the promotion of vocational education for such occupations It also outlines methods which have been used with success in planning and developing training programmes, and indicates ways in which Federal, State and local trade and industrial educational agencies can assist in the organization of vocational training for such occupations Incidentally, the Bulletin should serve a useful purpose in educating the general public in the work and problems of the public services, as has been done very successfully in Great Britain in certain civic exhibitions

New Antarctic Land

IN a slender volume illustrated with photographs and maps ' My Last Expedition to the Antarctic, 1936–1937 (Oslo Johan Grundt Tanum 1938), Mr L Christensen has recounted all too briefly the voyage of the *Thorshavn* to the Wilkes Land and Enderby regions of the Antarctic A brief voyage resulted in important work largely through the help of flying In Lars Christensen and Ingrid Christensen Lands (Kemp and MacRobertson Lands) the mountain ranges were photographed and mapped The most important discovery, however was that of the missing land between Crown Prince Olav and Princess Ragnhild Land, where from 34° to 40° E Prince Harald Land was found from the air A long range of mountains was noted in the interior Thus practically the entire coast line of Antarctica from the Weddell Sea eastward to the Ross Sea is now known and it would appear that in many parts mountains arise through the ice sheet at greater or less distances from the coast In several parts, rocky coasts or outlying islands suggest landing places for ground work Mr Christensen brought back geological specimens from several of his landings, but he says nothing of their nature

Communication Equipment for Vehicles

To the *A W A Technical Review*, published by the Amalgamated Wireless (Australasia) Ltd , of July Dr G Builder and J D Gilchrist have contributed a paper on communication equipment for vehicles Since about 1924, specific instructions for one or more units has been effected extensively either by radio telegraphy or telephone broadcasting This only needed the fitting of receivers in the fleet units the reports back to the organization headquarters being made when necessary by the ordinary telephone service The advantages of two way transmission led very soon to the use of telegraphic transmission from the units to headquarters when it was necessary to acknowledge instructions and make reports This as a rule required trained radio operators both on the units and at headquarters As development progressed, the use of telephony rapidly became common and duplex working was adopted The improvement in the equipment has now made such services almost equivalent to the normal wire line telephone services In some cases it is possible to dial any one mobile unit from headquarters, causing a bell to ring in the mobile installation The personnel of the mobile units therefore, have not to keep continual watch and are not distracted by calls which do not concern them It is feasible to arrange a dialling number calling either all the units or a group of them simultaneously These highly developed systems are rare, but they indicate the inevitable trend of development in the near future The use of crystal control of transmitter and receiver frequencies has proved of the greatest value in this connexion. One of the earliest applications was to police work and this has proved of great value in preventing crime and arresting criminals.

Tuberculosis in Tunisia

In his inaugural thesis (*Thèse de Paris*, No 365, 1938), Dr M H Thamer states that in Tunisia, which is a country of 2,608,313 inhabitants with a mixed population consisting mainly of Tunisian Mussulmans (2,335,623) with Tunisian Jews (59,485) and Europeans (213,205) the mortality from tuberculosis is much higher among the Mussulmans than in the other two groups. In Tunis alone there are about 4,000 tuberculous Mussulmans, and tuberculosis alone is responsible for more than a third of all the deaths from epidemic diseases. Further proof of the high incidence of tuberculosis among Mussulmans is furnished by army statistics, according to which 0·59 per cent of the Mussulman soldiers are affected as compared with 0·25 per cent of the Europeans. Moreover all the Tunisian practitioners are agreed that the number of tuberculous subjects is increasing yearly in enormous proportions, and that the immense majority of the cases are highly infectious and run a rapidly fatal course. At the present time the means for combating tuberculosis in Tunisia are quite inadequate. The only institution for detecting cases is the Mussulman Dispensary at Tunis, while barely 84 beds are available for all the cases of pulmonary tuberculosis *in a population of more than two millions*, among whom there are more than 6,000 deaths from tuberculosis yearly. There are at present no institutions in Tunisia for the prevention of tuberculosis among Mussulman children. The following measures, according to Dr Thamer, are urgently required: (1) for children, the creation of open-air schools, holiday colonies and a preventorium; (2) for adults, the establishment of five sanitary districts for Tunis, Susa, Sfax, Ket and Bizerta respectively, in each of which there should be a tuberculosis dispensary and the provision of about fifty hospital beds; (3) there *should also be a sanatorium of about a hundred beds* in the suburbs of Tunis; (4) afterwards the antituberculosis campaign should be extended to the smaller towns and the rural districts which constitute about three quarters of the total population of the country.

Government Scientific Publications

Most scientific workers are aware that from time to time research papers of immediate interest to them in their own particular work appear among Government publications. Even to those who make the fullest and most regular use of such publications, the admirably written and printed "Brief Guide to Government Publications" which has recently been issued by H.M. Stationery Office will probably come as a revelation of the extent and importance of the contribution to scientific, industrial and agricultural research which comes from such sources. Whether in agriculture, economics or social questions, education, medicine and public health, transport and communications, science, industry and technology, H.M. Stationery Office not only supplies innumerable publications containing up-to-date information on specialized subjects, but is also to an increasing extent the channel through which the results of both pure and applied research are published. A very lucid but comprehensive description of the chief Government publications in all these fields as well as in others of less direct interest to scientific workers is contained in this useful guide, and not the least of its merits are the brief but clear accounts of how Government publications are sold and of the catalogues, lists and bibliographies of such publications which are available.

Research on Coal Utilization

The British Coal Utilisation Research Association has decided to establish an experimental station in London. Premises have been secured at West Brompton, and are now being equipped. Dr D H Bangham, lately professor of chemistry and dean of the Faculty of Science, Egyptian University, Cairo, who has made important contributions to the physical chemistry of charcoal, cellulose and other carbonaceous materials, has been appointed the senior member of the scientific staff, and will take charge of a group of programmes connected with the use of coal. Mr J S Hales, who will take charge of the Domestic Appliances Department, has worked at the Fuel Research Station on the measurement of smoke and the operation of coke fires, and has since served on the research staff of a manufacturer of domestic solid fuel burning appliances. Mr R T Hancock, formerly associate editor and contributor to "Kemp's Engineers Handbook", has been appointed head of the Intelligence Department and editor of the Association's monthly bulletin.

An Electrodeposition Exhibit

Many examples of the varied applications of electrodeposition were shown at a special exhibition held at the Science Museum, London, in 1935. The success of this exhibition prompted the arrangement of a smaller permanent exhibit, which has been generously presented by the Electrodepositors' Technical Society. The main features of the original exhibition have been incorporated in a single case, which is now on view in the Chemistry Collections of the Science Museum. One of the most interesting sections of the exhibit deals with research, and has been arranged by the Research Department, Woolwich. Here may be seen *the results of the systematic* studies of electrodeposition problems made at Woolwich and elsewhere during the past twenty years.

Crystals, Molecules and Atoms

In a review which appeared in Nature of September 10, p 455, of the second volume, entitled "The Fine Structure of Matter", of Dr C H Douglas Clark's treatise on atomic and molecular structure, reference was made to the omission of modern quantum theory from Part 3, entitled "The Quantum

Theory and Line Spectra' Dr Douglas Clark has written pointing out that his complete work has been subdivided for convenience in publication, and that an advertisement of the scheme printed as frontispiece shows that the concluding Part of Vol 3 will deal with modern quantum mechanics Papers relating thereto have been sorted for inclusion in Vol 3, and the Part recently published contains the classical treatment only Thus while in the opinion of the reviewer, modern quantum mechanics should have received attention already, Dr Douglas Clark believes that his plan, which follows the historical order of development as far as possible will prove satisfactory

Health Organisation of the League of Nations

THE April number (7, No 2) of the *Bulletin of the Health Organisation* is entirely devoted to the teaching of hygiene based on a report by Prof Jameson, Prof Pittaluga and Dr Stampar on certain European institutes and schools of hygiene The June number (7, No 3) contains papers on the assay of morphine and cocaine the sero diagnosis of syphilis, nutrition and nutritive requirements, and undulant fever in France The final article deals with the significance of codeine as a habit forming drug, this does not appear to occur and the medical use of codeine is therefore not a social danger

Guide to Official Statistics

THE annual volume entitled Guide to Current Official Statistics of the United Kingdom is now published for 1937 (London H.M Stationery Office 1*s* net) The greater part of the book is a subject index in which every entry is followed by a list of related publications each referred to by its official number This is followed by a numerical list of publications The arrangement makes reference easy, and the book shows the wide range of valuable statistical and other matter that is available

Announcements

THE Lord President of the Council has appointed Dr G Stafford Whitby, at present director of the Division of Chemistry, National Research Council, Canada, and formerly professor of chemistry at McGill University, Montreal, to be director of the Chemical Research Laboratory, Teddington, in succession to Sir Gilbert Morgan, who retired on September 30 Dr Whitby is expected to take up his duties early in 1939

THE Council of the Royal Society of Edinburgh, with permission of the Hon Lord Robertson, have caused to be incised on the house at 14 India Street, Edinburgh, the following inscription

JAMES CLERK MAXWELL
NATURAL PHILOSOPHER
BORN HERE 13 JUNE 1831

THE Hermann Göring foundation ' Reichsjägerhof has sent an expedition to Greenland for six or seven months investigation of animal and plant life as well as to make geographical and meteorological observations

AT a recent session of the Health Section of the League of Nations, an international commission was appointed to promote uniformity of standards for patent medicines Dr Charles H Hampshire, of London, was appointed chairman, and the other members are Profs H Baggesgaard of Copenhagen, E Zunz of Brussels M Tiffeneau of Paris R Eden of Zurich, L van Italie of Leyden and Mr Ernest Fullerton Cook of Philadelphia

ONE of the Hunterian professorships of the Royal College of Surgeons of England has been awarded to Dr Donald W G Murray of Toronto, who will deliver his lecture in London next year This is the second time that this award has been made to a Canadian, the other occasion being in 1924, when Dr William E Gallie, of Toronto was so honoured Dr Murray has been appointed for his work on heparin, which has been done in conjunction with Prof C H Best, professor of physiology in the University of Toronto

DR WU LIEN TEH, for thirty years in the Health and Medical Service of the Chinese Government, including the directorship of the Manchurian Plague Prevention Service and of the National Quarantine Service, recently retired to his home in Penang He was editor of the *National Medical Journal* now known as the *Chinese Medical Journal* for fifteen years, and was founder and later president of the Chinese Medical Association

THE Central Association for Mental Welfare has decided, with the approval of the Board of Control to hold courses and establish a diploma for workers engaged in the teaching and training of low grade mental defectives The course will be held from January until December 1939, and the first two terms will be spent in approved occupation centres The third term will be spent in London and will consist of theoretical and specialized practical work Further information can be had from the honorary secretary of the Association, 24 Buckingham Palace Road S W 1

ACCORDING to official statistics, more sugar and margarine are consumed in Denmark than in any other country in the world During the period 1930–34, the annual consumption of sugar in Denmark was 54 kgm per inhabitant as compared with 49 5 kgm in England, 46 3 kgm in the United States, 25 6 kgm in France and 10 3 kgm in Poland

THE *Internationale Zeitschrift für Psychoanalyse* and the journal *Imago*, the official organs of the International Psychoanalytic Society, which are both edited by Prof Freud, have ceased publication The *International Journal of Individual Psychology* is also suspending publication

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 838.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

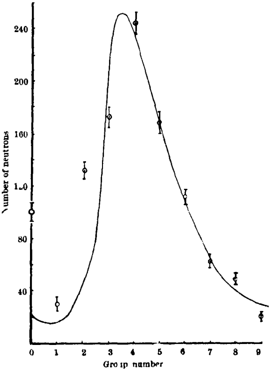
Velocity Distribution of Thermal Neutrons

WE have been developing during the past year an apparatus to make possible the study of neutrons of known energies within the thermal region. In principle, the apparatus consists of a device for producing a burst of neutrons lasting about 0·5 millisecond at intervals of 5 milliseconds. The source is surrounded by paraffin to slow the neutrons down to thermal energies, and these neutrons are then detected by a boron tri-fluoride chamber 5·4 metres away. The electrical pulses from the chamber are amplified and fed to a cathode ray oscillograph. Time signals are also received by the same amplifier and oscillograph whenever the bursts of neutrons occur. Since the neutrons take an appreciable time to cross the 5·4 metres between source and detector, a pulse from the chamber will be recorded later than the time signal corresponding to the burst which produced the neutron, and the distance between the two is inversely proportional to the velocity of the neutron. The traces on the oscillograph screen are photographed on a rapidly moving film, and the distances between the time marks and the pulses measured after development. From an analysis of these measured distances the velocity distribution of the neutrons can be inferred.

The source is a tube of the Oliphant type yielding deuterons, which strike a target of heavy ice. The discharge producing the ions has a voltage of about 20 kv. and is made intermittent by means of a beam of light interrupted by a tuning fork. This light falls on a photo-electric cell the current from which is amplified until it can control the 20 kv. discharge. To accelerate the ions we use a field of between 200 and 250 kv.

The accompanying graph shows the distribution between ten sub-divisions of the period of 1,556 neutrons, the faster neutrons appearing to the left. We have calculated the distribution to be expected if Maxwell's distribution law held for the neutrons, taking a temperature of 15° C., and assuming that the efficiency of the boron counter is inversely proportional to the velocity of the neutrons; it is shown on the figure by the curve. A correction, of the order of 20 per cent, has been made to the observed counts to allow for neutrons which did not follow the direct path between source and detector. This was done by making an experiment with a thick boron absorber in the direct path of the beam, and subtracting the result after correcting for the relative strengths of the neutron source under the two conditions.

The curve is adjusted to fit the experimental count for the middle division, and shows reasonably good agreement for the slower neutrons. At the zero of the time scale appears a group of fast neutrons which have not been slowed down by the paraffin to thermal energies. The discrepancy at divisions 2 and 3 may be due either to a peculiarity in the absorption of boron affecting the efficiency of the chamber at these velocities or to the hydrogen in the paraffin not being free. This may delay the achievement of equipartition of energy and affect some velocities more than others. We hope to examine the first suggestion by measuring the absorption of the neutrons of different energies by a boron screen.



○ EXPERIMENTAL OBSERVATIONS; VERTICAL LINES INDICATE STANDARD DEVIATIONS.

It will be seen that our apparatus constitutes a 'velocity spectrometer' for slow neutrons. A suggestion for constructing such an apparatus has been put forward recently by Milatz and Horst[1] and Alvarez[2] has described an apparatus which bears the same relation to ours that a monochromator does to a spectrometer, but we believe that the results reported here are the first to be recorded by the method.

Decomposition of Organic Peroxides

CONTINUING the investigation on the alkyl peroxides[1] and their relation to combustion phenomena, we have now obtained data on ethyl hydrogen peroxide, and propyl hydrogen peroxide

Ethyl hydrogen peroxide decomposes heterogeneously in the temperature range 140–200°, the rate of reaction being in accord with the expression for adsorption derived from the Langmuir isotherm, due allowance being made for the buffering effect of unchanged peroxide and decomposition products In agreement with this result, packing the vessel greatly increases reaction rate It was also found that coating the surface with salt increases the reaction rate, which may be connected with the suppressing effect of salted walls on the reactions of hydrocarbon and oxygen The products of the peroxide are mostly liquid at room temperature and include acetaldehyde and formaldehyde

At higher pressures the decomposition is homogeneous, explosive, and is attended with light emission The products of the decomposition are chiefly gaseous, and resemble those obtained from explosion of the mixture $C_2H_6 + O_2$

Propyl hydrogen peroxide was not obtained pure but the preparation used (60 per cent by iodometric method) formed propionaldehyde on heating at 200°, together with a gas containing propylene, ethylene, methane, hydrogen and carbon monoxide No explosive decomposition has yet been observed

Both the above compounds initiate markedly the slow reaction $C_3H_8 + O_2$, although they were found to reduce the induction period, they did not, however, affect the subsequent reaction rate, that is, in the expression $\omega = A(e^{\varphi t} - 1)$ only A, and not φ is changed

Their initiating effect can be nullified by poisoning (for example, with salt) the surface of the reaction vessel, which leads to the conclusion that the initiation takes place *after* a collision of the peroxide with the wall, which can direct the decomposition in two senses

$$\text{(i) peroxide} \xrightarrow[\text{clean wall}]{} \text{initiators}$$

$$\text{or (ii) peroxide} \xrightarrow[\text{poisoned wall}]{} \text{inert products}$$

This conclusion is in agreement with deductions from the observed accelerating effect of inert gases on the reaction $C_3H_8 + O_2$, for if the first reaction product is a peroxide, the reaction

$$\text{(iii) peroxide + fuel} \xrightarrow[\text{(in gas)}]{} \text{chain carrier,}$$

will be favoured at the expense of reaction (ii) A possible alternative explanation of the effect of the inert gas would be that it is more adsorbed on the poisoned surface than on the clean surface

To settle this point, further experiments on the effect of inert gases on the decomposition of these peroxides are in hand

It is noteworthy that hydrogen does not accelerate the slow oxidation of propane

Mechanism of the Rearrangement of Phenyl Ethers

WHEN certain phenyl ethers are heated at their boiling points, the non aromatic group migrates from the oxygen to the nucleus The more important groups which so migrate are allyl, benzyl and *tert*-alkyl If the rearrangement of some of these ethers is effected in a suitable solvent, the migrating group is transferred in part, to the solvent Thus by heating a quinoline solution of benzylphenyl ether, benzyl quinoline is formed together with the normal products of the rearrangement Toluene is also formed

These observations find a satisfactory explanation if the assumption be made that the preliminary phase of the rearrangement is the elimination of the migrating group as a free radical Thus toluene results from the disproportionation of the benzyl radical—a reaction known to occur with free radicals[1] The transference of the migrating group to the solvent arises out of its reaction with the free radical The assumption that free radicals take part in the reaction makes clear the observation, hitherto inexplicable, that the rearrangement of benzylphenyl ether is very materially assisted by the presence of metals such as zinc or copper[2]

Splitting of the Hæmocyanin Molecule by Ultra-violet Light

INVESTIGATIONS along different lines (ultracentrifugal sedimentation[1], X ray analysis[2]) have shown that the proteins contain particles possessing the hall mark of individuality and therefore are, in reality, giant molecules We have good reason to believe that the particles in protein solutions and protein crystals are built up according to a plan which makes every atom in it indispensable for the completion of the structure Primary protein reactions are therefore elementary acts which must, of necessity, obey the laws of quantum mechanics[3]

From this point of view, it would seem of interest to test the action of various energy quanta on proteins under such conditions that complications by secondary reactions are reduced to a minimum The experience with protein dissociation reactions accumulated in this laboratory[1] indicates that the forces holding the large blocks of very big molecules together are less strong than the forces acting between the dissociable parts of smaller protein molecules The chance of observing the primary process caused by the absorption of an energy quantum, therefore, appears to be most favourable in the case of proteins of very high molecular weight

We accordingly chose the hæmocyanin of *Helix pomatia* (molecular weight 6,740,000) as protein material for our first experiments Splitting of this molecule by ultra sonic waves has recently been observed in this laboratory[4] As energy quanta, we used ultra violet light Hæmocyanin solutions of various pH were exposed to the radiation of a quartz mercury lamp By means of ultracentrifugal sedimentation determinations, it was found that at a pH of 6 2 a splitting into half molecules occurs Prolonged irradiation causes denaturation, finally resulting in complete precipitation It is of interest to note that at *p*H 6 2 a further splitting of the half molecules does not take place At *p*H 7 4, however, both halves and molecules of smaller size are formed By means of suitable filters, it was found that the photochemical action is confined to the region of wave length in which the 'protein part of the molecule absorbs (2 800 A and shorter wave lengths) The band corresponding to the absorption of the prosthetic group (3 700–3 200 A) is inactive

From these observations we conclude that the weakest bond in the molecule of *Helix* hæmocyanin is that holding the two halves together To split up further by ultra violet light the half molecules, an increase in the number of ionized groups is necessary

We hope to gain further information by extending these experiments to other high molecular proteins and by using other kinds of energy quanta

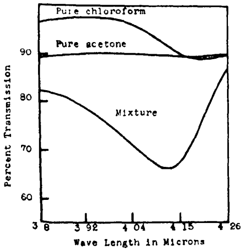
Association of Unlike Molecules through Hydrogen Bonds

IN donor solvents such as acetone and dioxan the position of the OH fundamental of water alcohols or phenol depends upon the solvent so as to indicate hydrogen bond formation between the solute and the solvent[1] Using CH_3OD I have extended the work on alcohol mixtures to include new solvents many of which absorb in the 3 μ region and hence cannot be studied with ordinary alcohol Most of the amines apparently form very strong hydrogen bonds with an OH or an OD group—that is in general they produce longer shifts in the OD band than do oxygenated solvents like ethers and esters



ASSOCIATION BAND IN CHLOROFORM ACETONE MIXTURE (MOLE FRACTION 0 5, CELL THICKNESS 0 015 CM)

An interesting case of association between unlike molecules is that of chloroform with other liquids[2] I have observed an associational band in the region of 4 μ for mixtures of chloroform with donor solvents such as pyridine, ether and acetone Considering with other factors, the position of the band and the manner of its variation in position and intensity for the different mixtures, I believe it to be an NH or an OH vibrational band resulting from a hydrogen bond formed by the sharing of the proton of the CH chloroform group with the N or O of the solvent One of the bands is shown in the accompanying diagram A similar, but weaker associational band was found for some bromoform solutions In all previous infra red studies of hydrogen bonding, only shifts in the bands of either the solute or solvent were observed—no new bands were found This seems to be the first direct observation of the new band which would be found in any case of hydrogen bonding, and hence I consider it the most definite evidence yet given for the existence of hydrogen bonds

A more complete report of these results will appear elsewhere

Very Small Intensity of the Red OI Triplet during the Auroral Displays of September 14 16

IT has been shown in previous papers[1, 2] that the red aurora of type *A* owes its redness to the enhancement of the red OI triplet $({}^1D_2 - {}^3P_{0,1,2})$ and that the relative intensity of this triplet and the frequency of the red auroras of type *A* seem to follow the sunspot frequency[3, 4] This rule was found to hold for spectrograms obtained since 1923 and up to the winter season 1937–38

As we approached the present sunspot maximum the red auroras of this *A* type and the intensity of the red triplet became very pronounced indeed On spectrograms obtained during the winters 1936–37 and 1937–38, the red line 6300 was usually about equally as strong as, and sometimes much stronger than the green line[3, 4, 5]

b Sept. 15–16, 1938
exp. 2045–2400

Very brilliant auroral displays appeared at Oslo during the two nights September 14–15 and 15–16 this autumn On both nights we took several auroral spectrograms on panchromatic plates (Agfa Isopan) *Although the green line 5577 appeared with great density on the plates the red line 6300 was only just visible on one of the spectrograms* The result is illustrated in the accompanying figure, which gives photometer curves for two of the spectrograms Only one of these curves shows the red line

Thus the average intensity of the red line 6300 relative to that of the green one was very small indeed throughout these auroral displays Not only the red OI triplet, but also the red bands of the first positive group of nitrogen were relatively very weak

As a result of the weakness of the red part of the spectrum, the auroras appeared green or bluish The small intensity of the red triplet is very interesting when seen in connexion with the fact that we are just at a sunspot maximum and it will be of great interest to see whether this small intensity of the red triplet is maintained throughout this winter and during the next few years If that is the case, it would mean that the intensity of the red triplet suddenly drops when the sunspot frequency has reached its maximum and that consequently the agency which is effective in producing the enhancement of the red OI triplet is not directly connected with the sun spots, but with some other solar phenomenon such as flocculæ or prominences or with some kind of active matter carried to high solar levels as the result of solar activity

Scattered Reflections of Radio Waves from a Height of more than 1 000 km

Besides the two main divisions of the ionosphere the *E* and *F* layers at heights of 120 km and 250 km , more or less irregularly occurring reflecting layers have been observed Magnetic storms and auroras are usually accompanied by an increase of the height of the *F* layer *F* layers with an equivalent height of 400–500 km are often observed during and after magnetic storms

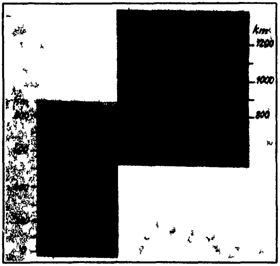

Fig 1

Scattered reflections 850 1200 km. equivalent height Recorded July 7, 1938, 18h 0m –18h 5m M E T on 7 65 Mc /sec

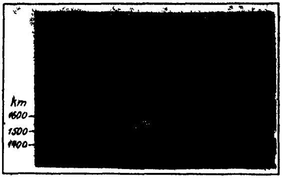

Fig 2

Scattered reflections 1300–1600 km equivalent height Recorded July 9 1938 16h 45m 16h 50m M E T on 9 0 Mc /sec

During recent months, experiments with a pulse transmitter with considerable output have been made using frequencies which were higher than the critical penetrating frequencies of the *F* layer the latter being controlled and recorded by a second set consisting of a receiver and a transmitter of moderate output The output of the larger transmitter was more than 50 kw in the pulse the aerial used was a horizontal half wave dipole the distance between the transmitter and the receiver was 150 m

On a number of afternoons and evenings, scattered reflections from a region lying between 850 km and 1,600 km equivalent height were recorded Fig 1 is a record showing scattered reflections between 850 km and 1,200 km equivalent height, and Fig 2 shows scattered reflections with 1,300 km to 1,600 km equivalent heights On the latter figure the white line indicates a ground wave 180° out of phase with the pulse emitted Since a 50 cycle circuit was used for the oscillograph this indicates a time difference of 1/100 sec which corresponds to an equivalent height of 1 500 km The echoes observed on the oscillograph screen are faint and the amplitudes rapidly varying They seem to be similar to the scattered reflections from the 100 km level recently described by Eckersley[1] and Appleton[2], and an explanation of these high echoes as due to ionospheric clouds seems to be probable

A detailed study of the appearance of these high echoes will be published elsewhere

The Electron Neutron Interaction

Recently, we described the results of experiments which led us to the conclusion that electrons are emitted from atoms when they interact with fast neutrons by some hitherto unknown process[1] On the other hand, Kallmann and Kuhn[2] have shown that gamma rays are emitted in the D–D reaction and that the neutron electron interaction postulated by us is not necessary to account for their results

Recently, we repeated our experiments using the coincidence method of two counters instead of a single counter method We constructed a pair of thin walled, semi cylindrical counters placed close side by side, and only simultaneous discharges taking place in both counters were recorded In this way we could get rid of many ambiguities with which one inevitably meets in experiments with a single counter For example the effect of recoil atoms is completely avoided, and the complete protection of the counters from the X rays excited in the discharge tubes becomes unnecessary, because the double counter system is insensitive to low energy electrons The latter circumstance was a decisive advantage in that it reduced the effect of the secondary gamma rays excited in matter in the direct neighbourhood of the counter

With this arrangement we confirmed in the first place that, when carbon was used as the secondary electron emitter the radiations coming from the target and sensitive to the double counter system consisted chiefly of gamma rays in agreement with the result of Kallmann and Kuhn But in the second place, when lead was used as the electron emitter a definite indication was observed that the electrons are emitted by the direct action of fast neutrons As we have already stated the postulation of the new effect is only necessary when the effect is observed in the case of light elements (see also Seaborg and Grahame[3]) Our present results can be accounted for by the existence of gamma rays from the target together with the internal conversion of the lead nucleus excited by the neutrons The disagreement with our former result seems to have come from the error involved in the estimation of the effect of the secondary gamma rays excited in the walls of the counter and that of the recoil atoms in the counter We should like to express our regret for this error

As to the origin of the gamma rays coming from the target, their intensity is of the same order of magnitude as would be expected from gamma rays excited in the substance constituting the target (glass) and the Dewar vessel for liquid air cooling the target It is, however, probable that they are inherent in the D–D reaction But their intensity is too low to relate them directly with the low-energy neutron group found by Bonner[4] The quantum energy of the gamma rays was estimated by the method of Bothe and Becker and it was found to be about 2 Mev The value is that to be expected from Bonner s result, but it is indistinguishable from the quantum energy of the gamma rays excited in most of the substance by the D–D neutrons

Details of this work will be published shortly in the *Proc Phys Math Soc Japan*

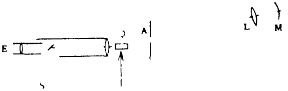
A New Method of Measuring the Velocity of Light

IN determining the velocity of light by Fizeau s toothed wheel the number of eclipses per second cannot be made more than about half a megacycle Thus the method requires great distances In two modern determinations, that of Karolus and Mittelstaedt at Leipzig in 1926, and that of Wilmer C Anderson at Harvard in 1937, the toothed wheel was replaced by a modulated Kerr cell and the frequency varied in the one case from 3 to 7 megacycles per second, and in the other case from 7 to 56 megacycles per second I have recently replaced the Kerr cell by a piezo electric quartz oscillator working at 115 mega cycles per second, and have thus been able to use Fizeau s method with a very short base line

The accompanying diagram represents the arrangement *Q* is the quartz The periodic electric field is applied in the direction of the arrow, and under its influence stationary ultrasonic waves are formed At the rarefactions and condensations the density of the quartz is altered thus its refractive index varies periodically and if parallel light is incident in the direction of the axis of the telescope the quartz acts on it like an intermittent diffraction grating This intermittent grating takes the place of Fizeau s toothed wheel The first order spectrum is as bright as the direct image



Monochromatic light from the source *S* is reflected down the telescope by a Gauss eyepiece The aperture *A* is placed in such a position that only a first order spectrum gets through The light then travels along an optical bench *AL* and is reflected back on its path by the lens mirror combination *LM* If when it returns to *Q* the grating is in action the first order spectrum is diffracted along the telescope to the eye of the observer at *E* if on the contrary, the quartz atoms are momentarily in their mean positions there is no diffraction Thus when the lens mirror combination is drawn back along the bench the image undergoes a periodic change in intensity As the grating forms twice in each period of the oscillator and the light has to traverse the path both going and returning, the positions of the mirror which give minima are only about 65 cm apart The first position at 32 cm from the quartz cannot be obtained owing to the aperture *A* getting in the way but the others which lie within the range of the bench, at 97 cm 162 cm 227 cm 292 cm and 357 cm , are all easily visible

The method is still in process of development, and will later be described in full It is too soon to estimate its possibilities, but at present it seems better than the other methods for measuring the velocity of light in liquids

The method was discovered during the course of an investigation supported by the Carnegie Trust for the Universities of Scotland, and I have been indebted to my colleague Dr John Thomson for freely placing his knowledge of short wave wireless at my disposal

Automatic Operation of Ciné-camera and Lighting Arrangements for Time Lapse Studies

The ciné camera provides a convenient means of recording the growth of plants and fungi, or other very slow movements. The method employed is to expose one or more frames of a film at regular intervals over the period of study. The camera is operated through the single frame crank or release either by hand or automatically. Where artificial lighting is necessary, lamps are also switched on at the appropriate moment. The apparatus required for automatic operation is generally elaborate and expensive. The design of a relatively simple and cheap form may therefore be of interest to investigators and others.

C
8V
CONTACTS OPERATED BY LEVERS AND CAM ON CLOCK

A Relay operating lamps. B Relay operating solenoid D. C Transformer. D Solenoid operating camera by lever and cable.

The device described below was developed initially for use in filming the growth of wood destroying fungus and for demonstrating the efficacy of preservative treatment of wood. Single frame exposures were required at intervals of 15 minutes over a continuous period of about thirty days. The objects being filmed had to be illuminated only while each frame was taken, as exposure of the fungus to intense light, for other than very short periods, was liable to affect its growth.

Apparatus. The ciné camera is operated by means of a solenoid (see accompanying diagram), the single frame release being connected by Bowden cable to a lever, the free end of which is pivoted to the armature. The solenoid and the lamps for illuminating the objects are connected to the mains and controlled by mercury tube relays. A small transformer supplies 8 v. current to the latter. The circuits containing the relays are opened and closed by reed contacts operated by levers and a cam on the minute hand shaft of an eight day clock.

The method of operating the contacts is a modified form of that sometimes used in electrical master clocks. The cam is four sided, so that the contacts are closed every fifteen minutes. Each contact is moved by a pair of followers, the inner ones being pivoted to the clock frame and the outer followers being pivoted to the inner at their mid points. The differences in length of the four cam followers govern the sequence and duration of closing and opening the contacts. The inner followers are in each case shorter than the outer and when they are dropped by the cam the pivots of the outer followers are lowered giving angular motion to the latter and so closing the contacts. When the outer followers are dropped in their turn by the cam they resume their original position relative to the inner followers and open the contacts. The sequence is as follows. The inner follower for the lamp relay contact falls first; a second or so later the inner follower for the solenoid relay contact falls. The outer follower for the latter then falls after a suitable period has elapsed and the solenoid circuit is opened. Soon after, the outer follower for the lamp circuit falls. During the next fifteen minutes the followers are gradually raised by the cam until the operation is repeated.

This arrangement has the advantage that the loading on the clock movement is small and uniform, without tendency to retard or stop the clock when the contacts are operated. The timing is accurate and readily adjustable by slight alteration in the lengths of the followers. Any number of operations from one to thirty or more per hour can be obtained by using suitable cams, larger diameters being required, of course, for the greater frequencies.

When films prepared in this manner are projected at normal rates, the otherwise imperceptible growth or displacement of the object is shown and rhythmic movements may become visible.

Sampling Lake Deposits

Work by the Freshwater Biological Association during the past year has directed attention to the importance of the deposits at the bottom of lakes as a means of interpreting their history since the Ice Age[1] and similar work on both freshwater and marine deposits has been progressing in other parts of the world[2]. Cores from the floor of lakes or the sea have usually been taken with a sampler consisting of an open ended pipe driven vertically into the deposit by its own weight (for example, Bigelow tube), by a hammering device, by exploding a charge at its upper end[3], or by screwing it into the deposits by means of connecting rods operated from a pontoon[4]. Such methods have the disadvantage that the deposits tend to be compressed and distorted by the pipe, so that the resulting core fails to give an accurate picture of the original stratification. The apparatus described in this communication was designed by one of us (B. M. J.) to avoid these difficulties, it has been tested successfully on Windermere, and should have application to similar problems elsewhere

Fig 1 shows the whole apparatus with the sampler proper (*F*) at the bottom, extension tubes (*E*) above it, of sufficient length to penetrate the deepest deposit to be sampled, and above these a length of guide tube on which slides a driving weight (*D*) The gear (*C*) for closing the sampler is carried on a flange at the upper end of the guide tube A bridle of cable supports the whole apparatus and works the driving weight The top of the bridle is hooked to a trip release (*B*) on the end of the main cable (*A*)

The sampler proper is shown in cross section in Fig 2 in the open position (*A*) and closed position (*B*) It consists of an outer tube, of 2½ inch bore, of which one third of the circumference is cut away, and an inner half tube The cut side of the outer tube is closed, except for a small longitudinal opening, by a face plate The inner half tube is carried by radial arms on a shaft, which passes upwards to the closing gear, so that when the shaft is rotated the inner half tube projects through the longitudinal opening, passes through an arc of a circle, and closes against the face plate The top and bottom ends of the inner half tube are closed by thin diaphragms, for the passage of which cross slots are left in the face plate The bottom end of the outer tube is closed by a solid steel point which slides on its attachment to act as a valve

Fig 1.

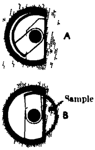

Fig 2

A, Sampler open, B Sampler closed

In use, the whole apparatus is lowered by a single cable from a pontoon, with the sampler in the open position Its own weight is sufficient to penetrate the upper soft layers of the deposit, and it can be driven down to the required level by raising and dropping the sliding weight A messenger weight sent down the cable then releases the trip, which disconnects the main cable from the driving weight and allows a fine by pass cable to be tightened by hauling up the main cable Tension on this fine by pass cable, transmitted through a pulley and skew gears (*C*), revolves the central shaft, and with it the inner half tube, thereby enclosing a core of the bottom deposit in the sampler (Fig 2, *B*) Loss of any part of the sample is prevented by the diaphragms mentioned above As the fine by pass cable completes the closure, a second strong by pass cable (to the left of *B*, Fig 1) becomes tight and takes the weight of the whole apparatus as it is hauled out of the deposit The latter process is made easy by the valve at the bottom of the sampler allowing water to pass down the tube to fill the hole left in the deposit On reaching the surface, the apparatus is laid horizontally and the closing gear is turned backwards to expose the core which is then transferred to a trough in which it is stored for examination

The experimental sampler was made to collect cores only 4 feet long but deeper deposits were explored by using extension tubes (*E* Fig 1) to take successive but overlapping cores at increasing depths In this way cores of 9 feet in length were obtained in Windermere There seems however, no reason why a longer and better constructed apparatus on the same plan should not be capable of extracting undisturbed cores from considerably greater depths of deposit and under many fathoms of water

The advantages of this apparatus over others previously used for similar purposes are that (1) it is worked from a pontoon with only a single cable and is therefore applicable to almost any depth of water, (2) there is no need for connecting rods to the surface, (3) for obtaining cores at successive depths in the deposit there is no need for devices to ensure that the sampler enters the same hole again, (4) there is no compression or appreciable distortion of the core, at any depth, because the inner half tube cuts laterally along the arc of a circle into undisturbed deposit

Nature of the Gonadotropic Hormone from Pregnant Mare Serum

In a recent communication, Hartman and Benz[1] reported on the carbohydrate content of gonadotropic hormone preparations from pregnancy urine and pituitary gland A similar result was previously reported by Karl Meyer[2] who investigated a product obtained from Prolan by reaction with iodine The product obtained contained 11 07 per cent total nitrogen 16 4 per cent total reducing sugar of which 7 72 per cent was hexosamine The acetyl value was 3 16 per cent If these figures are recalculated on the iodine free substances, the figures are 11 9, 17 7, 8 3 3 4 per cent respectively

We have been occupied lately with the purification of products obtained from pregnant mare serum, and we found that they contain considerable amounts of reducing sugar, hexosamine and acetyl groups They give strongly positive Molisch and Elson Morgan reactions for hexosamine The most interesting fact we derived from our investigations is that apparently the relation of total nitrogen and hexosamine nitrogen is in some way characteristic for the purity of the products

In analysing different products prepared from mare serum which are in the market as well as our own products, we have found that in the average product this quotient, N_{hex}/N_{total} is between 1/34 and 1/48 The purest product gave 1/14, whereas the above cited preparation from human pregnancy urine[2] showed a relation of 1/18 4 On the other hand, using the analytical data of Meyer[3], on the glycoprotein, ovomucoid *a*, a quotient of nearly 1/9 is obtained

Our findings would confirm the assumption of Karl Meyer and John W Palmer as to the mucoid nature of gonadotropic fractions

It may be of interest that the gonadotropic hormones apparently do not contain cystine

Production of Mammary Carcinomas in Mice of a Susceptible Strain by the Synthetic Œstrogen, Triphenyl Ethylene

It is well known that in certain inbred strains of mice, many of the females develop spontaneous mammary tumours Few or no tumours occur in the males of these strains or in the females spayed before puberty When, however, these males are injected with œstrone over prolonged periods, a number develop mammary tumours

We have produced mammary carcinomas in the males of such a strain by the injection of a synthetic œstrogen Fifty three males of the *R* III strain (Dobrovolskaia Zavadskaia) received weekly a sub cutaneous injection of 5 mgm of triphenyl ethylene in oil, the dose being later reduced to 3 mgm The injections were started before the age of sexual maturity and have been continued up to the present time Twenty six mice are still alive after 28 or more weeks of treatment

So far, ten mammary carcinomas have developed in nine male mice (one mouse developed two tumours) They are of the same histological type as those which occur spontaneously or which are produced by the injection of a natural œstrogen in this strain, that is, they are papillary adenocarcinomas with cystic and degenerative areas The tumours appeared at 18, 19½, 21 (two mice), 23, 24 (two mice), 26 and 29 weeks of treatment

Several tumours have also developed in females of the same strain ovariectomized before puberty and afterwards injected with triphenyl ethylene Their histological examination is at present in progress

Twenty nine males and twenty one females (non spayed) of a strain which does not spontaneously develop mammary carcinoma (black agouti) have also been injected with triphenyl ethylene for a similar period, and no tumours have so far developed

A Hæmoglobin from Bile Pigment

Under this title, Lemberg, Legge and Lockwood have described in Nature of July 23, p 148, "a new hybrid hæmoglobin" formed by special treatment of hæmoglobin – ascorbic acid solutions In the summary given, p 166, one finds the following "The new compound, like hæmoglobin, combines reversibly with oxygen and carbon monoxide but the non protein part of its molecule is a bile pigment closely related to verdohæmatin This might give the impression that the existence of bile pigment globin compounds was not known before

In 1932, Barkan[1] suggested that the easily split off blood iron (leicht abspaltbares" Bluteisen), discovered in 1925 by him[2], may be a step in the formation of bilirubin Later Barkan and Schales[3] pointed out that the two fractions E and E' of the 'easily split off' blood iron accompany the hæmoglobin in the circulating blood as intermediate products of bilirubin formation E and E' are hæmoglobin like compounds in which the bearer is an undenaturated globin, whilst the prosthetic group is a hæmin or hæm derivative with an opened porphyrin ring similar to that in Lemberg s 'verdohæmochromogen' We called these compounds pseudohæmoglobins, and the prosthetic groups pseudohæmin and 'pseudo hæm' We suggested the use of the prefix 'pseudo for such products which resemble in many points the 'true' ones and differ from them only by the opening of the porphyrin ring, indicating by the letter α, β, etc, at which methene group the opening took place (in our case α pseudohæmoglobin, α pseudo hæm, etc) We were able to show[3] that the two native fractions E and E differ by the valence of the iron It is in the divalent form in E (E is a pseudo hæmoglobin *in sensu strictiori*) but trivalent in E (E' is a pseudomethæmoglobin) We were able to transform E into E and vice versa[3] Barkan and co workers described many properties of the pseudo hæmoglobins E and E The most important fact is that the bile pigment – globin compound E combines reversibly with oxygen and carbon monoxide according to the 'distribution equation, and that the relative carbon monoxide affinity (by which is meant the ratio of the affinity for carbon monoxide to that for oxygen) is rather greater in the case of E compared with hæmoglobin (Barkan and Berger[4]) The pseudo methæmoglobin E' (like the methæmoglobin) does not react in this way with oxygen and carbon monoxide

Recently Lemberg observed that verdohæm (pseudo hæm after our definition) unites with native globin to give a hæmochromogen and not a hæmoglobin Therefore he assumed as a working hypothesis that in the disintegration of hæmoglobin the alteration of the globin part precedes the oxidation of the prosthetic group[5] Barkan and Schales[6], on the other hand, have emphasized that the existence of E and E' (that is, of *iron containing bile pigment – globin compounds*) in the normal red blood cells gives evidence that an oxidation of the prosthetic group must be the first step in the breakdown of hæmoglobin The new statement by Lemberg and his co workers that an iron containing bile pigment – globin compound is readily formed from hæmoglobin seems, when considered in connexion with our previous work, to support our opinion mentioned above

There is no evidence, however, indicating whether or not the new hæmoglobin product of Lemberg and co-workers is identical with our pseudohæmoglobin found in erythrocytes. Thus it is doubtful whether the new name 'choleglobin' is necessary and suitable. The choice of rather unsystematic names in bile pigment nomenclature is, we find, a hindrance rather than a help to discussion.

Some other details in the letter of Lemberg and co-workers may be discussed elsewhere.

A Viable Homozygous Deficiency in *Drosophila melanogaster*

THROUGH combination of fragments of chromosomes from two complicated rearrangements (obtained in my work dealing with the w^{mt} position effect, 1938, in the press), one of which causes a light w^{mt} and the other a very dark w^{mt} eye colour, the first having the break to the left and the other to the right of the *w* gene, a stock was obtained which had no *w* gene in its genotype. Since the cytological observations show that the breaks occur near each other, or even at the same point in both the original aberrations, it was concluded that only one gene, namely, the gene white, was deficient. The cytological data agree well with the phenotypical actions of the *w* deficiency which does not differ from a simple *w* mutation causing the white eye colour. The cytological observations agree also with the data obtained by numerous authors showing the position of the *w* gene in the $3C_2$ region of Bridges' salivary chromosome map. But in the *w* deficiency combinations the $3C_2$ band is not thinner than in the normal chromosome.

This may serve as evidence for the conception that the genes are really localized in the intrabandular areas. In this case the *w* gene must be included between the disks $3C_2$ and $3C_3$ in the X chromosome map. It may be also that this finding, which does not agree with the data of Shultz (1938), who has shown that in the *w* mutations the $3C_2$ disk is thinner than in the normal chromosome, is caused by the fact that in both of the original aberrations and in their compound, the $3C_1$ and $3C_2$ disks, which are translocated from chromosome IV to chromosome II L, stain more deeply by aceto-carmine, that is, more nucleic acid is present.

The *w* deficiency males and females (the latter have been obtained by crossing *w* deficient males to notch^8 females) do not differ from the typical w^w mutations, and have no other pleiotropic effects. The increased sterility of the *w* deficient males is due probably to the original sterility effect present in one of the aberrations involved.

It is the second undoubted case of viable homozygous deficiency; the first was obtained by H. J. Muller (1935, the *y, ac* deficiency). The phenotypical effect which is caused by the *w* deficiency corresponds well with Muller's theory (1932) of the action of hypomorphic and amorphic mutations. Thus, the *w* mutations are typical amorphic mutations and probably some of them are caused by real deficiencies. The viability of the deficiencies and the absence of pleiotropic effects in these flies shows a high degree of discontinuity of the hereditary substance in the sense that the role taken by some genes is very low and that they affect few physiological functions of the whole organism. This may be caused by a high degree of duplication of genes, partially not homologous with each other.

Thermal Conductivity of Mud Brick

INVESTIGATIONS of the thermal conductivity of mud brick, of which the methods of manufacture with mud and straw seem to have remained practically unchanged through thousands of years, have been made with small- and large-scale apparatus.

Results with small samples 10 cm. in diameter and from 1 cm. to 2 cm. thick have given results ranging from 3·8 × 10^{-4} calories per sq. cm. per 1° C. temperature gradient per sec. with much straw to 8·0 × 10^{-4} c.g.s. units with minimum straw.

The results with mud brick walls built vertically in 150 cm. × 140 cm. × 28 cm. frames vary from 3·9 × 10^{-4} to 6·0 × 10^{-4} c.g.s. units. The weight of water in the bricks was found to vary by some 15 per cent according to the humidity of the air. Such bricks appear considerably better heat insulators than ordinary burnt bricks now used in constructional work, but are less heat insulating than the best cellular concrete.

Bluffing by Eclipse Prediction

LIVY'S description of the Roman general, C. Sulpitius Gallus, warning his men before the battle of Pydna (168 B.C.), that an eclipse of the moon would take place on the following night is well known. He gave a scientific explanation of the phenomenon so that they should not take it as an adverse omen. The Macedonians, on the other hand, were, according to the historian, unprepared and thoroughly alarmed.

Less familiar is the very effective use of a solar eclipse by the Byzantine Emperor, Alexius I Comnenus, who figures so prominently in the history of the First Crusade. To quote the words of his biographer, his daughter Anna Comnena:

In the course of the discussion a certain Nicolas, one of the Emperor's secretaries, came up to him and whispered in his ear, 'You may expect an eclipse of the sun to take place to-day', and on the Emperor's expressing a doubt, he swore with an oath that he was not lying. Then the Emperor, with his habitual quick wittedness, turned to the Scythians and said, 'I appoint God as Judge; and if a sign appears in the heavens this day, you will know for a surety that I have good reason for suspecting, and therefore not receiving, your embassy because your leaders are not sincere in their overtures for peace. If, however, no sign appears I shall stand convicted of having been wrong in my surmise Before two hours had passed the light of the sun failed and the whole disk was darkened by the moon s passing over it At that sight the Scythians were terrified (The Alexiad translated by Elizabeth A S Dawes London Kegan Paul 1928)

In fiction, we have Mark Twain and Rider Haggard making use of this device, Rider Haggard s description of the duration of an eclipse being a stock example of a scientific howler in literature It would be interesting to find who first thought of this form of bluff in imaginative writing The earliest reference I can discover is in the romance The Prairie Bird , by the Honourable (Sir) Charles Augustus Murray My copy is dated 1854, but, according to the Dictionary of Natural Biography, this book was published in 1844

Points from Foregoing Letters

EXPERIMENTS have been made by G E F Fertel Dr P B Moon, Prof G P Thomson and Dr C E Wynne Williams on the distribution of velocities among the neutrons emitted from a source surrounded by paraffin By using as the source an intermittent discharge they find that with one apparent exception, the distribution follows the Maxwell law

Ethyl hydrogen peroxide decomposes heterogeneously in the temperature range 140–200° according to E J Harris and Prof A C Egerton Coating the surface of the vessel with salt increases the reaction rate and at higher pressure the decomposition is explosive The authors discuss the action of this and other organic peroxides upon propane oxygen mixtures

From a study of the rearrangement of benzylphenyl ether and similar ethers in suitable solvents Dr W J Hickinbottom suggests that the observed facts are best explained by assuming that the rearrangement is dependent on the intermediate formation of free radicals

Irradiation of hæmocyanin (mol weight 6 740 000) with ultra violet light of wave length corresponding to the absorption band due to the protein part of the molecule (around 2800 A), leads to the splitting of the molecule, according to ultracentrifuge experiments by Prof The Svedberg and S Brohult The authors consider that primary protein reactions are elementary acts which obey quantum mechanics

A graph showing a new absorption band in the region 4μ in mixtures of chloroform with acetone, due to association between the molecules of these solvents is submitted by Prof W Gordy, who states that this is the most definite evidence yet published for the existence of hydrogen bonds between associated molecules

A very small intensity of the OI triplet in the auroral spectrum during the displays of September 14–16, which resulted in the auroras having a greenish or bluish tinge, is reported by Prof L Vegard, who suggests that the enhancement of that radiation in the auroral spectrum prior to the sunspot maximum may be due to some kind of active matter carried to high solar levels as the result of solar activity

Dr Leiv Harang and Willi Stoffregen have obtained scattered reflections of radio waves from heights between 850 km and 1,600 km equivalent height, using a pulse transmitter with considerable output The frequencies used were higher than the critical penetrating frequencies of the F_2 layer The scattered reflections are explained as due to ionospheric clouds

Dr R A Houstoun describes a variation of Fizeau's method of determining the velocity of light, in which the toothed wheel is replaced by an intermittent diffraction grating This enables the range to be diminished to a four hundredth of its value

An arrangement for recording the growth of plants and other very slow movements by photographing at fixed intervals with a ciné camera is described by P Harris Advantages claimed for the new arrangement are that the clock movement is small and uniform and the timing accurate and easily adjustable, so that from one to thirty or more operations per hour can be readily obtained

A device for sampling lake deposits in which the inner half tube cuts laterally along the arc of a circle so as not to disturb the deposits, is described by B M Jenkin and C H Mortimer The apparatus is worked from a pontoon with only one cable without connecting rods to the surface and samples at successive depths can be taken without the sampler having to enter the same hole again

G Fleischer Dr E Schwenk and K Meyer find that the proportion of hexosamine in relation to the total nitrogen in the gonadotropic hormone present in pregnancy urine is of the same order as that in the glycoprotein ovomucoid α The authors consider that this supports the view concerning the mucoid nature of gonadotropic extracts

Dr J M Robson and G M Bonser report that injections of triphenyl ethylene (a synthetic œstrogen) lead to the production of tumours in male mice of a strain in which females alone develop spontaneous tumours

Prof G Barkan and O Schales have pointed out that in the red blood cells there are present iron containing bile pigment – globin compounds These pseudohæmoglobins accompany the hæmoglobin in the circulating blood as intermediate products on the way to bilirubin formation The recent work of Lemberg and his co workers described in NATURE is believed to support the opinion of Barkan and Schales that an oxidation of the prosthetic group and not an alteration of the protein part may be the first step in the breakdown of hæmoglobin to bilirubin

Through combination of fragments of chromosomes from two complicated rearrangements found in two varieties of the fruit fly (*Drosophila*), one of which causes a light and the other a dark eye colour, I B Panshin has obtained a stock in which the gene white is absent in the genotype Cytological observations support the view that the genes are localized between the dark staining bands of the chromosomes

Research Items

Indians of the Copper River Delta, Alaska

A DETAILED record and analysis of the culture of the Eyak Indians by Dr Kaj Birket Smith and Dr Frederica de Laguna ('The Eyak Indians of the Copper River Delta, Alaska', *Kgl Danske Videnskabernes Selskab* København Levin and Munksgaard, 1938 Pp 592+18 pl) is based mainly on observations made during an expedition to Prince William Sound in the summer of 1933 The Eyak it had been estimated in 1930, were distinct from Eskimo, Tlingit and the Atna, or Athapascan speaking tribes of the Copper River Valley The hypothesis then suggested that they were a group of the Athapascans who had come from the interior down the river is here tested and discussed in the light of intensive ethnographic study Eyak culture is an extremely complicated thing, as might be expected from their geographical situation on the borders of three or four of the principal culture areas of North America, and close to the main cultural gate between the two hemispheres The basic structure seems fairly clear More than eighty Eyak elements, namely, 45 per cent of the 183 traits studied, are classed with the ice hunting culture They belong to all phases of human life, comprising dwellings, dress, conveyance, house utensils and tools, hunting methods and weapons, magic and religion, etc The elements of the snow shoe culture, on the other hand, are exceedingly few in number and of a casual character This culture can never have been adopted as a whole The analysis of Eyak culture adds strength to the evidence of a circum Pacific culture stream, as 27 of its elements seem to belong here Further, the greater part of the 22 Tlingit elements must be included among circum Pacific traits, as in most instances they are elaborations of Old World forms, which have drifted back to the north The origins of the remaining elements can be classified roughly as follows Asiatic without belonging to any well-defined complexes previously mentioned (9 elements), Eskimo Thule culture and north west coast, chiefly from the southern area of the latter (7 elements), Eskimo Thule traits (10 elements), North East Coast and Plateau, or in a few cases only, the latter (17 elements)

Blood-groups in India

IN a paper on the blood group distribution in India (*J Genetics*, 36, No 2) Dr Eileen Erlanson Macfarlane discusses previous results and adds new ones from different parts of India Different castes as well as races have been compared, and, as might be expected, the castes differ in their blood groups The rather small samples indicate that, in Bengal *A* is similar in different castes, as would be expected if it is of ancient origin, but the percentage of *B* increases and that of *O* decreases in the lower castes On the Malabar coast these conditions are reversed, the higher castes being highest in *B* It is evident that *B* has spread both socially, in different castes, and geographically, and it is suggested that *B* may have spread from a single source in north central India during recent millenniums In Bengal, the Mohammedan blood groups are similar to those of low caste Hindus in the same region, which accords with the tradition that they were low caste converts from Hinduism in Moghul times The relatively low *B* in Cochin is accounted for by the fact that migratory movements from farther north missed the Malabar coast, the lower castes and pre Dravidians being high in *A*

Frequency of Multiple Births

MR ALBERT V T DAY of 180 Kings Highway Westport Connecticut, writes to direct attention to the empirical rule connecting the observed frequencies of twin, triplet and quadruplicate births namely that approximately one birth in 80 is of twins, one in 80^2 of triplets, and one in 80^3 of quadruplets He suggests that the discovery of such a consistent rule in inorganic physics would not be treated as a mere mathematical coincidence If the said rule is a functional expression of some real biological mechanism its true basic ratio may be 81, derived as 9^2 or 3^4

Food Pellets of Owls

BY studying the activities of a captive short eared owl (*Asio flammeus*) Dennis Chitty has added to knowledge of its food habits (*Proc Zool Soc*, Ser A, 108 267, 1938) The formation of pellets it is said, is not due to any special diet or structure of the alimentary canal and Guérin regards their ejection as a deliberate act the time of which is determined at will by the bird In the short eared owl the time of ejection of pellets was found to be related to the weight of the meal previously taken, although as a rule pellets were retained longer at night than during the day At each ejection the owl completely emptied its stomach, the pellet representing the residue of one or two meals of which the combined weight seldom exceeded 40 gm Biochemical analysis of the food taken by the owl shows that pellet ejection involves a low percentage of ash, and particularly of calcium in the retained food matter The data gathered in these experiments have been used to estimate the food requirements of an owl in natural conditions (though the results may be considerably off the mark) It is concluded that in a year a short eared owl would eat more than 47 lb of voles and mice, and probably more than 95 lb but less than 142 lb Where some relationship is known between the size of owl and vole populations in the same area, this represents a consumption of the vole population by owls at a rate of 0 02–0 05 per cent of the population per day—not enough to make any serious impression upon a vole plague

Moulds of Blue Cheese

MOULD fungi which can grow under the conditions of low oxygen tension provided by the cracks of certain cheeses are somewhat variable, and many species have been described It was suggested by Thom in 1930 that all these species were really cultural variants of one, namely, *Penicillium roqueforti* S Dattilo Rubbo has re examined the question in great detail (*Trans Brit Mycol Soc*, 22, Pts 1 and 2, 174–180, Aug 1938), and his results substantially confirm those of Thom A new variety, *viride*, of *P roqueforti* has been obtained from Blue Cheshire cheese, but this is the only variant of significant permanence isolated from Roquefort Gorgonzola, Stilton, Blue Vinney, Wensleydale and Blue Cheshire products Dolce Verde cheese, however, provides an isolated exception, for its organism is related to *P expansum*, a blue mould associated with the rotting of fruit

The Pitch-Crust Fungus

A DETAILED paper by W H Wilkins (*Trans Brit Mycol Soc*, 22, Pts 1 and 2, 47–93, Aug 1938) gives an account of the spore germination and methods of infection of the common pitch crust fungus, *Ustulina vulgaris* This fungus can attack standing timber, and causes subsequent decay The investigation shows that while spores can germinate upon living trees, penetration is very slow Dead wood, on the other hand, allows germination and ready penetration and it is suggested that in Nature the organism is somewhat saprophytic and grows first upon non living timber Saturated wood and a temperature above 10° C for not less than 24 hours are the necessary conditions for spore germination and the age of the spores is also a potent factor The optimum temperature for germination is 25–30° C and the optimum pH is 6 Spores germinate upon, and penetrate, ash, beech, elm, horse chestnut, lime and poplar, but not oak The collected result of these experiments is, however, considered to suggest the improbability of spore transmission in temperate climates, and other methods must be considered

New Zealand Forest Fungi

NUMEROUS references to published work upon fungi which attack New Zealand forest trees have been collected by Mr T T C Birch (*N Z J Forestry*, 4, 2, 1937, or *N Z State Forest Service Bull* 9, 1938) For each fungus species, the New Zealand hosts are given, distribution of the parasite is indicated, a description of the type of damage caused is given, and then the references to published work It is thus possible to obtain with ease a conspectus of New Zealand forest pathology Many of the sixty two species listed are common in Europe, though not always as parasites *Schizophyllum commune*, for example, is a parasite in New Zealand, but is usually considered a saprophyte in Great Britain Seven species, the hyphæ of which are probably mycorrhizal, are also mentioned, and beneficial symbiosis of *Boletus luteus* with *Pinus radiata* has been proved by Mr Birch

The Earth's Crust

A RECENT paper by Neil R Sparks (The Eureka Earthquake of June 6, 1932 , *Bull Seism Soc Amer* , 26, 13–27 , 1936) has aroused considerable interest in that the thicknesses of the crustal layers and the velocities of waves in them turn out to be rather different from those determined for Europe In consideration of this, Stoneley (*Bull Seism Soc Amer* , 28, 191–195 ; 1938) has reviewed the observations, determining the standard deviations He finds the thicknesses of the granitic and second layers to be 12 6 ± 2 5 km and 12 2 ± 1 9 km , compared with the 16 and 14 km given in Sparks's paper The velocities of the P waves in these turn out to be 7 15 ± 0 065 and 7 53 ± 0 073 km /sec respectively, using Sparks's assumptions The most recent determination by Jeffreys (*Mon Not Roy Astro Soc* , Geoph Supp , 4, 210 , 1937) for European earthquakes is 17 ± 2 km and 9 ± 3 km for the thicknesses of the granitic and intermediate layers respectively, and P^* is 6 498 ± 0 026 km /sec

Absorption of the CH_2 Group near 3μ

IN a previous communication (*Proc Roy Soc* , A, 162, 419 , 1937), Drs J J Fox and A E Martin recorded observations made on the CH vibrations of some organic compounds in the 3μ region They indicated that, whilst a CH_2 group in general gave rise to two C–H vibration bands, in some molecules, especially those containing a benzene ring, the C–H units interacted to give several bands Continuing this work, the same authors have examined a large number of compounds containing CH, CH_2, and CH_3 groups arranged in different ways, and a recent paper (*ibid* , 167, 257–281 , 1938) contains details of the absorption in the 3μ region, of seven compounds in which CH_2 groups are attached to the rest of the molecule by single bonds By reviewing the data available for ethylene, the authors have been able to explain the CH_2 bands observed in more complicated molecules When only one CH_2 group is contained in the molecule, the two bands observed correspond to the CH valency vibrations in and out of phase , but as the number of CH_2 groups in the molecule is increased, coupling between them causes an increase in the number of bands Thus dioxan has four strong bands Using a model of the form aldehyde type which approximates to the molecules studied, the observed frequencies can be explained assuming that the CH force constant is 4 52 × 10^5 dynes/cm It is found that the mass to which the CH_2 group is attached, and the various other force constants involved, have only slight effects on the position of the CH_2 absorption bands in the 3μ region, except in rare instances where the bonds connecting the CH_2 groups to the rest of the molecule are strained Compounds containing CH_3 and aliphatic CH groups will be dealt with in a forthcoming communication

Ultra-Rapid Processing of Radiographs

BY ordinary methods of processing, the minimum time between the taking of a radiograph and the viewing of the finished film is about ten minutes Development takes five minutes and the remaining time is needed for a quick rinse and sufficient fixing to render the film legible In certain surgical operations—the Smith Petersen nail operation is a case in point—frequent radiographs are required for inspection during their progress, and the surgeon is held up while these are being prepared It is now possible by mean of a process devised by Messrs Kodak, Ltd , to view the films within one minute after exposure By the use of the new ultra rapid developer which this investigation has produced, the development of normally exposed films takes only fifteen seconds A quick rinse of ten seconds in clean water and fixation for thirty seconds in a special bath complete this stage of the process, so that the surgeon's loss of time is greatly reduced It is stated that films prepared by this special process can be made available for future reference by giving them a final fix in a normal hardening bath and then thoroughly washing them The radiographic quality of the films produced by this new method compares well with that obtained under the more familiar processing conditions

Aggregation of Purified Tobacco Mosaic Virus

DR HUBERT S LORING, DR MAX A LAUFFER, AND DR W. M STANLEY, Rockefeller Institute for Medical Research, Princeton, New Jersey

THE point of view has been advanced by Bawden and Pirie[1] that purified tobacco mosaic virus consists of stable aggregates of many smaller units present in the infectious tissue extracts. Such aggregation has been stated to take place after purification by chemical means or after high speed centrifugation, and to result in a decrease in specific activity, in an increase in stream double refraction, and in an inability of the purified virus to pass ultrafilters which readily permit of the passage of crude virus. Similar conclusions have been drawn for purified latent mosaic virus[1]. It was early recognized that prolonged chemical treatment of tobacco mosaic virus with salts at room temperature resulted in a decrease in specific activity[2]. Later, other evidence was secured indicating that aggregation of virus occurred as a result of such treatment; hence there is complete agreement that the rather drastic chemical procedures used by Stanley[3] and by Bawden and Pirie[1] and others for the purification of tobacco and latent mosaic viruses and their strains resulted in aggregation.

TABLE 1

ACTIVITY AND STREAM DOUBLE REFRACTION OF TOBACCO MOSAIC VIRUS AFTER ONE TWO THREE AND FOUR SEDIMENTATIONS

Experiment	Activity*			Stream double refraction†			
	1	2	3	1	2	3	4
Original juice	466	2068	799	14.4	21.0	21.2	18.5
Sedimented and redissolved in supernatant juice	486	2243	798	17.7	19.9	19.5	19.8
Original juice	1152	970	609				
Sedimented and redissolved in water or buffer	1267	988	561	16.7	8.7	13.8	15.8
Twice sedimented virus	1777	2359	1221		18.0		11.0
Three times sedimented virus	2025	2052	1276			25.3	
Once sedimented virus	605	1413					
Four times sedimented virus	533	1163			36.0		27.0

* Activities are expressed as numbers of lesions obtained on 30–40 half leaves of *Phaseolus vulgaris* plants by a 1–2000 dilution in 0.1 *M* phosphate buffer at *p*H 7 for samples of juice and 10^{-4} gm per c.c. for samples of purified protein.

† Stream double refraction is expressed as the galvanometer deflections in mm. caused by undiluted samples of juice and re-suspended virus or by concentrations of purified virus equal to those of the once sedimented virus redissolved in water.

For this reason, other means for purification were sought by us. Highly active preparations were obtained from the infectious juice of young plants after three or four precipitations of the virus with ammonium sulphate, provided long exposure to the salt was avoided[3]. In more recent work, however, it was found that preparations obtained by means of high-speed centrifugation in the absence of salt possessed a high and uniform specific activity, and this method has been used almost exclusively[4]. It has seemed desirable to examine the nature of such preparations of purified virus in view of Bawden and Pirie's finding that all their purified preparations consisted of aggregated virus and their contention that centrifugation causes such aggregation.

The question of aggregation of tobacco mosaic virus has been studied by comparing the activity, the stream double refraction, and the filterability of virus before and after purification by ultracentrifugation. The virus was sedimented from clarified infectious juice by centrifugation at about 5° for $1\frac{1}{2}$ hours in a field of about 50,000 *g*. To determine the effect of one sedimentation the virus was redissolved in the supernatant juice from which it had separated, or in the same volume of water or 0.1 *M* phosphate buffer at *p*H 7. The solutions were then centrifuged at low speed to remove a small amount of insoluble material. To obtain more highly purified samples, the once sedimented virus dissolved in water was subjected to one or more additional sedimentations. The activity tests were made on leaves of *Phaseolus vulgaris* L. plants by the half leaf method[5], and the stream double refraction measurements in the apparatus previously described[6].

The results of the activity and stream double refraction measurements are shown in Table 1. When the sedimented virus was redissolved in the supernatant juice and the activity of the resulting solution was compared with that of the original juice at the same dilution, both sedimented and unsedimented virus produced about the same number of lesions. When the sedimented virus was redissolved in water and compared at the same dilution with the original juice again comparable numbers of lesions were obtained with both solutions, although the protein concentration of the former was only about 80 per cent that of the juice. As shown in Table 1, the stream double refraction of the once sedimented virus, whether redissolved in the supernatant juice in water, or in dilute buffer was about the same as that of the original juice. The combined activity and stream double refraction measurements demonstrate quite conclusively that one sedimentation under the conditions described failed to cause either an appreciable decrease in specific virus activity or an increase in stream double refraction, as would be expected if irreversible aggregation of the original virus had taken place. They also showed that such centrifugation resulted in practically complete sedimentation of the virus. In agreement with this the supernatant juice which had been poured off contained less than 1 per cent of the original virus activity and showed a negligible amount of stream double refraction.

The results of the activity comparisons and stream double refraction measurements of virus purified by two, three, or four sedimentations are also shown in Table 1. These samples were compared on a protein basis. The activity results are comparable to those found after one sedimentation in that no great change in activity took place after several sedimentations. A comparison of once and four times sedimented virus, however, showed a slight decrease in specific virus activity after four sedimentations. In agreement with this, four times sedimented virus showed a significant increase in stream double refraction If this is due to aggregation, then, in view of the activity measurements, the amount must either be relatively small or must be largely reversed at the dilution used for the activity measurements

The ultrafiltration experiments were carried out in the presence of 0 1 M phosphate and nutrient broth at a 1–5 dilution at about pH 8 under the conditions used by Thornberry[7] Ultrafilters of about 190 mμ and 330 mμ average pore diameter, kindly supplied by Dr J H Bauer, were used In each case the filterability of the virus was determined by comparing the activity of the solution on half leaves before and after filtration The results are summarized in Table 2 They show that once sedimented virus, redissolved in the supernatant juice, or virus purified by four ultracentrifugations, possessed about the same ability to pass ultrafilters of 190 mμ average pore diameter as the virus in the original juice Once sedimented virus, as well as clarified infectious juice, could be filtered through filters of 330 mμ average pore diameter without significantly affecting the virus concentrations The ultrafiltration results are, therefore, entirely comparable with the activity and stream double refraction measurements, except that the small amount of aggregation indicated by the two latter measurements in the case of the four times sedimented virus appears to be insufficient to affect its filterability through membranes of 190 mμ average pore diameter

TABLE 2

EFFECT OF SEDIMENTATION ON ULTRAFILTRATION OF TOBACCO MOSAIC VIRUS

Virus solution	Dilution*	Average pore diameter (mμ)	Activity†		Per cent virus in filtrate
			Before filtration	After filtration	
Infectious juice	1 100	190	483	203	42
Sedimented virus in supernatant juice			292	307	105
Four times sedimented virus			1038	382	37
Infectious juice	1 100	330	846	66	9
Sedimented virus in water			1782	1700	96
Twice sedimented virus			268	121	45

* Dilutions are in terms of the original juice The solvent in each case consisted of nutrient broth at a 1 5 dilution in 0 1 M phosphate at pH 8

† Number of lesions produced on 24 30 half leaves of *Phaseolus vulgaris* plants

The results of the three types of experiments described above fail to show an appreciable irreversible aggregation as a result of centrifugation They are in agreement with the finding of Loring[4] that latent mosaic virus purified by ultracentrifugation readily passed filters of 450 mμ average pore diameter, and the observation[5] that the tobacco mosaic virus nucleoprotein in clarified juice and that purified by ultracentrifugation have the same sedimentation constant. The latter observation, as has been shown by Lauffer[9] from theoretical considerations, indicates that the size and shape of the particles of purified virus are the same as those of the virus particles in the juice It is improbable that virus in untreated juice is in the form of prismatic plates as suggested by Bernal[10], for it has already been demonstrated that such virus consists of rod-like particles[4,11] Recent work indicates that tobacco mosaic virus has a molecular weight of at least 43×10^6, a length of at least 430 mμ, and an effective diameter[9] of about 12 mμ

The results obtained in the present work fail to confirm Bawden and Pirie's[1] report that one sedimentation causes great increase in stream double refraction, and indicate that tobacco mosaic virus purified by a few careful centrifugations is comparable in specific activity, in stream double refraction, and in filterability to the virus in untreated juice In view of unpublished observations that isoelectric precipitation or precipitation by means of ammonium sulphate at room temperature causes a loss of specific activity and an increase in stream double refraction of ultracentrifugally isolated virus, it is evident that the virus first isolated by chemical means, as well as preparations obtained later by us and by others by means of prolonged chemical treatment at room temperature, consisted largely of aggregated virus Preparations obtained by rapid chemical treatment in the cold or preferably by means of ultracentrifugation in the cold appear to be the only ones yet obtained that are comparable to the virus in untreated juice with respect to specific activity, filterability and stream double refraction

F C BAWDEN, Rothamsted Experimental Station, Harpenden, AND N W PIRIE, Biochemical Laboratory, Cambridge

WHEN we found that the infectivity and filterability of preparations of tobacco mosaic virus were reduced and the anisotropy of flow was increased by chemical methods of isolation, we suggested that linear aggregation had taken place[1,2] This is now confirmed by Loring, Lauffer and Stanley, but they claim that unaggregated preparations can be made by the use of a high speed centrifuge We found that sedimenting the virus increased anisotropy of flow, but we made no measurements of the effect on infectivity or filterability It was suggested by analogy with the chemically prepared virus that this effect was also a result of aggregation There is no necessary contradiction between our observations and those of the American workers We centrifuged for 3 hours at 25–30° C, whereas they used a more efficient centrifuge running at 5° C, furthermore, their measurements of anisotropy of flow were made at very much higher rates of shear[3] than were ours A lengthening of the virus rod would be expected to increase the readiness with which anisotropy of flow would be demonstrated rather than the total amount shown, and the changes which we have claimed might well be undetectable by their method.

Even if centrifugation does not cause aggregation, completely unaggregated preparations could be expected only from plants that have been recently infected, for aggregation occurs naturally in the sap of plants that have been long infected[4]

We have emphasized the need for caution in interpreting centrifugal data on systems which can, in some circumstances, aggregate It may be possible to isolate unaggregated tobacco mosaic virus by short periods of centrifuging in strong gravitational fields at a low temperature. But it is significant that four sedimentations cause an increase in anisotropy of flow detectable by the method of Loring, Lauffer and Stanley. It therefore seems improbable that one sedimentation should have no effect Also, until more adequate data on the activity, chemical composition and physical properties of virus preparations made solely by high-speed centrifugation have been published, it will not be possible to assess their purity

Dr. Kenneth M. Smith, F.R.S., Potato Virus Research Station, Cambridge, and **W. D. MacClement**, Molteno Institute, Cambridge.

Dr. Stanley and his colleagues draw the conclusion that tobacco mosaic virus is not aggregating after centrifugation since it passes a membrane of 190 mμ average pore diameter In our ultrafiltration experiments, we have found that this virus, after precipitation at *p*H 3 4, will pass through a membrane of smaller pore size than the foregoing and has an end-point under optimum conditions of 150–175 mμ This indicates an aggregation of some kind, since the accepted ultrafiltration end-point of tobacco mosaic virus in crude clarified sap is about 50 mμ In our opinion, therefore, it is not justifiable to draw the conclusion that the virus is not aggregated merely because it passes a membrane of 190 mμ average pore diameter Tobacco mosaic virus, however, which has been subjected to the full process of purification and will therefore take up the liquid crystalline state, has a filtration end-point greater than 450 mμ, it is clear, therefore, that intermediate stages of aggregation are possible

---

Origin of the Solar System

THE presidential address to the British Astronomical Association was delivered by Rev Dr M Davidson, on October 26, at Zion College, and dealt with the theories advanced to explain the system of planets and satellites of the solar system

After brief reference to certain electric theories, in particular to that of H P Berlage, which appeared in *Prof Roy Acad Amsterdam* in 1930–34, other theories which have held the field for a time were discussed The main objection to the old and rather attractive Laplacian hypothesis is the enormous discrepancy between the angular momentum that the rotating nebula must have possessed and that which the solar system possesses to-day. Further, the theory suggested that the planets were thrown off from the original sun by internal forces and were not removed by some outside agency, but, as the major planets have about 98 per cent of the angular momentum of the solar system and only about 1/700 of the total mass, this suggests the action of an internal body

The planetismal hypothesis of Chamberlin and Moulton did not receive so much attention in Great Britain as might have been expected The manner in which the planets were formed, according to this hypothesis, differs essentially from that which the more recent tidal theory assumes In the former case, they are assumed to have been built up slowly by accretions drawn into the original nuclei, in the latter case the once liquid planets received very little later accretions. The difference may not be of much interest to an astronomer but to the geologist it is of the utmost importance

The planetismal hypothesis is the parent of the more recent tidal theories, and naturally many of the objections to the latter will also apply to the former. Dealing with Sir James Jeans's theory, which first assumed a very extensive sun but later adopted the 'Roche model'—a body with a strong central condensation—Dr Davidson referred to a number of objections to the theory The greatest of these, he believes, is that which arises from a consideration of the distribution of angular momentum in the planets, per unit mass, as pointed out by Prof H N Russell The visiting star which was supposed to have produced the eruption from our sun must have made a very close approach, and, even under the most favourable conditions, it could not have produced ten per cent of the angular momentum per unit mass that the planets possess at present This seems to be sufficient, without any other objections, to condemn the theory

The recent theory of Dr R A Lyttleton was then dealt with This starts with the assumption that the sun was once a binary and that its companion was ejected by a visiting star, the filament formed by the usual disruption, which is supposed to occur in these cases, finally producing the planets and satellites, the latter by close approaches of planets However, as Dr H Jeffreys has shown, the satellites could not have been formed in the manner assumed, and Dr Lyttleton was forced to abandon his original explanation of these bodies, and to assume rotational instability of enormous primitive planets Jupiter and Saturn, according to this theory, were once a single extensive planet, and from the filament resulting from the disruption their satellites were formed, and even other independent planets His explanation of the origin of the primitive planets was severely criticized by Dr W J. Luyten and Dr E L. Hill In particular, they had shown that the visiting star, which must have removed the filament from the companion at least 20 astronomical units from the sun (half the distance of Pluto), required a velocity of about 100 km a second, and at such a distance from the sun the matter would escape. There are other objections, and Dr. Lyttleton, recognizing the validity of these, has modified the theory in one respect especially If the visiting star is greater than the companion of the sun, the conditions would obviously be more favourable, but, on the whole, it seems extremely doubtful if an explanation will be found along these lines Dr Davidson is of opinion that some much simpler explanation, not demanding so many *ad hoc* assumptions would be forthcoming, but this might be a long way off yet

In conclusion, Dr Davidson referred to the new satellites of Jupiter and to the fact that Mr J Miller had predicted a missing satellite (NATURE, Feb 5 p 245) Unfortunately, satellite x, for which an orbit had been computed, did not fit into the place predicted for it, as it was 7 million miles from Jupiter He felt, however, that there was a space about 2½ million miles from Jupiter in which a satellite would some day be discovered The fact that satellites vi, vii, and x are moving in similar orbits at nearly the same mean distances from their primary provides another problem for the cosmogonist Perhaps a shoal of minute bodies occupies this region, but naturally one can only conjecture on such matters

At the close of the address, Dr Davidson vacated the presidential chair, which was then taken by Mr B M Peek the newly elected president

---

Removal of Sulphur Acids from Flue Gases

In Great Britain there is manufactured annually about one million tons of sulphuric acid but a quantity of sulphur oxides much greater than this is discharged into the atmosphere by the combustion of coal In the last ten years it has become possible to reduce atmospheric pollution from this source The concentration of sulphur oxides in chimney gases is very low and so long as fuel consuming units were small and scattered the resulting damage was relatively inconspicuous Moreover any effective process for desulphurizing the gas would have been prohibitive in cost Engineers limited their efforts to reducing the visible pollution by smoke and grit

Technical developments in the generation of electricity compelled attention to the problem of cleaning flue gas Mechanical stoking made it possible to burn fine coal at high rates of combustion and caused the discharge of much grit and dust into the atmosphere The introduction of pulverized fuel accentuated the grit nuisance Economy of steam production and power generation was secured by working in ever larger units and the need for reducing the high cost of distributing electricity required that these units should be installed near the load The result has been the erection of huge coal burning units using inferior coal in large centres of population With the project to erect the generating station at Battersea, the danger of discharging large quantities of sulphur acids into the heart of London was recognized and the London Power Company was compelled to render its chimney gases innocuous before passing into the air Now the concentration of coal burning into large units while increasing the local intensity of atmospheric pollution, eased the technical problem of designing and operating economic processes of sulphur removal In a relatively short time the Battersea station was discharging into the air, flue gases almost free from sulphur The gases, before entering the chimney, were washed with large volumes of Thames water to which lime was added and the clarified effluent returned to the river

When the Fulham Power Station came to be enlarged, the authorities were able to insist that a similar standard of purity should be maintained, but in addition, that no effluent should be returned to the Thames, lest the alkalinity of the river water, already diminished by the Battersea plant, should be destroyed The very existence of the Fulham plant was thus dependent on devising a process which made no liquid effluent The wash liquor would inevitably become saturated with salts which must be removed as fast as made The salt in this case was calcium sulphate, which is prone to form a troublesome scale on surfaces and in a continuous process liable to block the plant

In an address delivered at a recent meeting of the London Section of the Society of Chemical Industry Dr R Lessing described the course of experiments which showed how the salt could be removed without scale formation Calcium sulphate solutions can persist in a supersaturated state, but this condition can be prevented if the wash liquor contains sufficient $CaSO_4, 2H_2O$ in suspension It was found possible to define conditions under which the flue gases could be washed continuously with a liquor containing in suspension about 10 per cent of $CaSO_4$ and working in a closed cycle Water removed by evaporation up the chimney was replaced and fresh lime was added to replace that removed by precipitation of lime salts An essential feature in the cycle was a delay tank where the desupersaturation of the liquor could proceed to a point where deposition of scale in the plant would not occur

This process has now been in operation at Fulham and elsewhere long enough to leave no doubt that gases can be discharged from chimneys practically free from sulphur acids without the production of a liquid effluent An important advantage of a washing process is the simultaneous removal of grit Mechanical methods of removing grit are only partially successful The electrostatic precipitator can retain grit almost completely but allows acid gases to pass into the air Moreover, the electrostatic precipitator is not certain under overload conditions such as arise when 'soot blowing is in progress

The cost of sulphur extraction during the first year's working at Fulham was 0 0144*d* per unit and will doubtless be reduced with further experience This may be a price well worth paying to reduce the damage due to sulphur in urban atmosphere Dr Lessing said that the washing of the chimney gases at Battersea and Fulham would eventually mean a reduction of sulphur pollution in the London area amounting to ten per cent This shows the importance of this striking success of chemical engineering

American Association for the Advancement of Science

Virginia Meeting

THE American Association for the Advancement of Science meets in Richmond for its first Virginia convention on December 26–31

On Monday evening, December 26, at the John Marshall Hotel, editors of all Virginia newspapers, members of the National Association of Science Writers, prominent officials of the State and of the American Association and others will be entertained at dinner by members of the local Virginia Section of the American Chemical Society planning committee, headed by Lloyd C Bird Sir Richard Gregory, editor of NATURE, is to be the principal speaker Austin H Clark, curator of the Division of Echinoderms at the Smithsonian Institution and formerly director of the press service for the Association, will be honoured at this meeting for his long service and untiring co operation with the Press of the world in helping to make available scientific news for the public

Dr George D Birkhoff, professor of mathematics at Harvard University and retiring president of the Association, will be the principal speaker at a general session on Tuesday night at the Mosque His subject will be "Intuition, Reason and Faith in Science Dr Wesley C Mitchell, professor of economics at Columbia University and president of the Association, will preside The address will be followed by a reception by the local committee to the Association and guests at the Thomas Jefferson Hotel

The joint session of the Society of the Sigma Xi and the Association will be held on Wednesday night at the Mosque with Dr W F Durand, emeritus professor of engineering at Stanford University, as the principal speaker Dr Durand is a past president of Sigma Xi, the leading honorary scientific fraternity of the United States and a member of the National Committee for Aeronautics His subject for the seventeenth annual Sigma Xi lecture will be 'Modern Trends in Air Transport"

On Thursday evening there will be a joint general session of the United Chapters of Phi Beta Kappa and the American Association at the Mosque The lecturer will be Dr Frank Pierrepont Graves, New York State Commissioner of Education, and his subject will be Is Education a Science ? '

The mental health symposium, one of the features of the meeting, will end on Friday night with a general session at the Mosque Dr C Macfie Campbell, professor of psychiatry at Harvard Medical School, will be the principal speaker

As a contribution to the general public, members of the local planning committee are arranging a public meeting at the Mosque for either Saturday afternoon or evening with Dr William M Mann director of the National Zoological Park, Washington, D C, as the speaker Dr Mann has kindly consented to show and explain his motion pictures taken in Sumatra during an expedition for specimens for the National Zoo This motion picture and Dr Mann's address will be one of the principal features for the public during the meeting

In order to commemorate the outstanding work of Virginia s first State geologist W B Rogers, after whom Mount Rogers in Southwest Virginia is named on the occasion of the Virginia meeting of the American Association, the Virginia Section of the American Chemical Society has organized a tour to include a visit to White Top and Mount Rogers in picturesque southwest Virginia The erection of a tower of native rock on top of Mount Rogers, which would give visitors and pilgrims to this beauty spot a view of five States, is one of the proposals for the memorial Prof Rogers, a graduate of the College of William and Mary, where his father was a professor, was appointed professor of natural philosophy at the University of Virginia, and first State geologist in charge of the Virginia Geological Survey in 1835 His work brought him national recognition as a leading Virginia man of science, and created a general appreciation of that day of the scientific possibilities in Virginia Dr Rogers helped in the formation of the Association of American Geologists and Naturalists He was elected president of the Association in 1848, when it was transformed into the American Association for the Advancement of Science, and in 1876 became president of the latter body

---

Laboratory of Saharan Biology

THE extent of investigations carried out by the French in the Sahara is well known to the British scientific world, and not a few British biologists have made that desert a field of their researches In the past, such explorations have had to take the form of more or less arduous expeditions, which prevented more lasting observations requiring a convenient and suitably equipped base The need of establishing such a base was recognized by French authorities some years ago, and all biologists interested in desert life will be glad to know of the existence of a Laboratory of Saharan Biology (Laboratoire de Biologie Saharienne) at Beni Ounif, in the south of the Oran province of Algeria and on the border of French Morocco.

The Laboratory occupies an old fort, which was abandoned as it had lost its military importance, and comprises several rooms with the necessary furniture and scientific equipment In a village which has grown around the fort one can obtain all the necessities of life, while its relatively small size enables one to reach unspoilt desert by a short walk The environs of Beni Ounif are exceptionally interesting for a biologist, since most of the types of desert environment can be found within easy distance *reg* (hard, pebbly desert), *hammada* (stony desert), *erg* (sand-hills), *oueds* (dry water courses) and a large oasis with date cultivation The Laboratory presents unique facilities, by its situation and equipment, for investigations on various problems of the ecology of desert plants and animals, which can be attacked by direct observation in the field combined with experiments on fresh material in the Laboratory

Owing to insufficient publicity, the Laboratory has remained hitherto practically unknown to biologists outside France, and it is to be hoped that this note will attract the attention of biologists who may wish to work on desert biology but believe that this must necessarily involve the discomforts of travelling and camping Beni Ounif is reached by train from Oran or Algiers in seventeen hours, and inexpensive accommodation can be found in one of the several local hotels Foreign research students are very welcome, and no charge is made for the use of the Laboratory Detailed information can be obtained from the director of the Laboratory, Prof Ch Killian Faculté des Sciences Algiers, Algeria

University Events

Cambridge —In accordance with its usual practice Trinity College announces the offer of a research studentship open to graduates of other universities who propose to go to Cambridge in October next as candidates for the degree of Ph D The value of the studentship may be as much as £300 a year Candidates must not have reached the age of twenty six years before May 1 1939 In certain circumstances, an election may be made to an additional studentship The same College offers as usual Dominion and Colonial exhibitions to students of Dominion and Colonial universities who wish to go to Cambridge next October as candidates for the degree of B A M Litt M Sc or Ph D These exhibitions are of the titular value of £40, but their actual value varies Further particulars may be obtained from the Senior Tutor Trinity College Cambridge

I Rothbarth has been appointed assistant in statistical research

The degree of master of arts has been conferred upon Dr J E Driver (London) University demonstrator in chemistry

At Emmanuel College Dr G R Owst, professor of education has been elected into a professorial fellowship

Prof R G W Norrish has been elected a member of the Council of the Senate

London —Dr H S W Massey, who has been since 1933 independent lecturer in mathematical physics in the Queen's University, Belfast, has been appointed as from January 1 to the Goldsmid chair of mathematics tenable at University College

The Chester Beatty scholarship in radiology of the value of £400 for one year has been awarded to Mr E P Allen This scholarship was established through the generosity of Mr A Chester Beatty for two years to enable students to study radiology in the United States

The John Marshall fellowship of the value of £500 a year for two years has been awarded to Mr K C Eden This fellowship was established under the will of the late Miss A B Marshall in memory of her father, Prof John Marshall

The following doctorates have been conferred D Sc in biochemistry on J F Danielli, D Sc in botany on Miss Ann C Halket, D Sc (engineering) on Prof J T MacGregor Morris

Science News a Century Ago

Royal Astronomical Society

On November 5, 1838, at a meeting of the Royal Astronomical Society a letter written on October 23 from Konigsberg by Bessel to Sir John Herschel was read, describing his efforts to determine the parallax of a fixed star Bessel began his letter Esteemed Sir,—Having succeeded in obtaining a long looked for result, and presuming that it will interest so great and zealous an explorer of the heavens as yourself, I take the liberty of making a communication to you thereupon Should you consider the communication of sufficient importance to lay before the other friends of astronomy I not only have no objection, but request you to do so With this view, I might have sent to you through Mr Baily, and I should have preferred this course as it would have interfered less with the important affairs claiming your immediate attention on your return to England But, to you I can write in my own language and thus secure my meaning from indistinctness

Bessel then went on to describe how to attempt the determination of the parallax of a star he thought of using Fraunhofer's heliometer, why he chose 61 *Cygni*, and the course of his observations which were begun in September 1824 After having his heliometer repaired, he resumed the inquiry and in March 1840 terminated a series of 402 measures

Botanical Society of Edinburgh

At a meeting of the Botanical Society of Edinburgh on November 8, 1838 Prof Graham read an account of a visit which he along with some friends, had paid to the west of Ireland in August, to examine its botanical productions It was stated that the mountains of Cunna mara (*sic*) present very little of the alpine vegetation with which the mountains of Scotland are clothed a difference probably arising from their structure the summits, or nearly two thirds of their height being composed of the most unproductive quartz Near the base of the mountains some micaceous soil exists, and there a little alpine vegetation was found The only peculiarity which the quartz presented was abundance of *Saxifraga umbrosa* (*athenæum*)

Prof Robert Graham was born at Stirling on December 7 1786 and died at Coldoch in Perthshire on August 7 1845 After practising medicine in Glasgow, he was appointed professor of botany in the University of Glasgow in 1818, being the first occupant of the chair Two years later he was transferred to the chair of botany at Edinburgh which he held until his death

The Australian Museum

It would not be easy to imagine, said the *Mechanics Magazine* of November 10, 1838, 'a more gratifying evidence of a young colony's progress in civilization than that which is given by a handsome volume, a few copies of which have lately reached this country The book is A Catalogue of the Specimens of Natural History and Miscellaneous Curiosities deposited in the Australian Museum' It is very handsomely printed 'by James Tegg and Co, at the Atlas Office, George street Sydney, an offshoot from the well-known 'Thomas Tegg, at the Old Mansion House, Cheapside, London''

Forthcoming Events

[*Meetings marked with an asterisk are open to the public*]

Monday, November 7

University College London at 5 —Dr J F Danielli The Permeability of Membranes (succeeding lectures on November 14 and 17) *

University of Leeds at 5 15 —Dr H Spencer Jones, F R S Solar and Terrestrial Relationships *

Royal Geographical Society at 8 30 —Miss G Caton Thompson Climate Irrigation and Early Man in the Hadhramaut

Tuesday, November 8

Royal College of Physicians at 5 —Dr Harold Scott Conquest of Disease in the Tropics (Fitzpatrick Lectures Succeeding lecture on November 10)

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene) at 5 30 —Sir Stanley Woodwark The Rise and Fall of certain Diseases concurrent with the Progress of Sanitation and Hygiene *

University College London at 30 —Prof P Pruvost Some Problems of Sub Surface Geology in Northern France (succeeding lecture on November 10) *

King's College London at 8 30 —Prof A Dalcq The Formation of the Pronephros and its Causes *

North East Coast Institution of Shipbuilders and Engineers Newcastle on Tyne —Sir William Bragg Pres R S The Molecular Basis of the Strength of Materials (Andrew Laing Lecture)

Thursday November 10

Royal Society at 4 30 —Prof E D Adrian F R S Some Problems of Localisation in the Central Nervous System (Ferrier Lecture)

London School of Economics at 5 —W G Eady The Care of the Unemployed (succeeding lecture on November 11) *

Friday, November 11

Physical Society (at the Imperial College of Science) at 5 15 —Prof A V Hill F R S The Transformations of Energy and the Mechanical Work of Muscles' (Guthrie Lecture)

Royal Institution at 9 —Sir William Bragg, Pres R S Combination Tones in Sound and Light"

Appointments Vacant

Applications are invited for the following appointments on or before the dates mentioned

Lecturer (woman) **in Mathematics** in the Froebel Educational Institute Training College for Teachers Grove House Roehampton Lane S W 15—The Principal (November 8)

Director of the Imperial Bureau of Forestry—The Secretary Executive Council of the Imperial Agricultural Bureaux 2 Queen Anne's Gate Buildings London S W 1 (November 15)

Four Assistants (grade III) for work on aeronautical electrical equipment at the Royal Aircraft Establishment South Farnborough—The Chief Superintendent (November 18)

Assistant Lecturer and Demonstrator in Zoology and Comparative Anatomy in University College Cardiff—The Registrar (November 19)

Lecturer (Chemistry) in the Department of Pure and Applied Science in Loughborough College Leicestershire—The Registrar

Human Evolution and Mechanization

IN an address* at the end of last year before the American Society of Mechanical Engineers Prof Earnest A Hooton of the Peabody Museum Harvard University surveyed the course of evolution in the primate stem regarding it as a series of adaptations in a progression towards the specifically human attributes of tool making and tool using He showed how each of the modifications in structure such as the development of the hand with its opposable thumb and sensitive finger tips of the foot as a movable point of balance of upright stature with the consequent visceral readjustments of stereoscopic vision and of the central nervous system and the changes in form size and complexity of the brain were all antecedent conditions in the attainment and elaboration of a material culture The results of recent observation and experiment with monkeys and apes have also shown how structure and mentality in each branch of the pithecoids has militated against the attainment of anything more than some rudimentary form of mechanical achievement while the failure to develop an articulate language has precluded the passing on of experience and acquired knowledge which is an essential element in human cultural progress

We will not attempt to follow Prof Hooton in detail as he traced the influence of the invention of tools from the time when it relieved man of the necessity of further structural adaptation in the struggle for survival—tools as he says made organic adaptation obsolete—to the dominance of the machine in modern civilization There are however two points which call for special consideration Of these the first is a development of the familiar principle that disuse of an organ leads to its atrophy Prof Hooton suggests that when human evolution emphasized cerebral development it diverted nutriment from other parts of the body and the less active organs diminished in size While however he goes on no man has need of the strength of the ape he ought to need the brains of a man he should not be able to survive with the brains of a moron The machine and mass production of modern civilization favour the survival of the physically unsound and the mentally impotent by relieving mankind of the opportunity or indeed the necessity for physical and mental exercise The second point maintained by Prof Hooton is that invention is the product of the individual and is accepted with reluctance by the many if indeed it be not actually suppressed though the conservatism of the masses is responsible for the preservation and stability of the culture already achieved

Prof Hooton intentionally paints in darkest colours the picture of present day trends in mechanized society which he regards as rushing headlong along the downward path on a well engineered road Man's mechanized science he says has so far outstripped his biological status and social ideals and behaviour that it has become a menace What we must do he concludes is to direct a modicum of that high intelligence and creative ability which is too much monopolized by mechanical science to the study of ways and means of repairing and improving the human machine

With this conclusion all will be in hearty sympathy especially in so far as it implies the building of a better race and the study of the capabilities stored up in our species through the millions of years of primate evolution which have culminated in man At the same time certain comments present themselves for consideration It is possible to exaggerate the deadening effect of mechanization on the human mind Much depends upon the individual and his character qualities and interests In the days before mechanization it was the deadening effect of manual labour of any kind now contrasted with mechanization which was blamed and often not unjustly for the inertia and the baseness of the masses in our population They always have been and always will be coarse in some degree while they are unleavened by the desire and the opportunity for self development Such an opportunity must now come in our modern civilization through the development of a regulated mechanization which will give labour the necessary leisure

* The Simian Basis of Human Mechanics or Ape to Engineer The Tenth Henry Robinson Towne Lecture delivered at the Annual Meeting New York N Y Dec 6–10, 1937, of the American Society of Mechanical Engineers Reprinted from *Mechanical Engineering* of January 1938 *Antiquity* of June 1938

But again surely the moron like character of the base mechanic is much exaggerated The mental and social effects of mechanization through atrophy of the powers of the mind and the dangers of passive receptivity induced by gramophone wireless and the cinema are patent indeed but are they really so serious as they are said to be ? The introduction of the talking film has placed the cinema more nearly on the level of the theatre as an educative and cultural influence Its failure is now in its material rather than in its method of presentation—this does not refer to natural history and other instructional films—and the shortcomings of the film as drama are being remedied rapidly Both cinema and wireless now reach thousands where formerly the theatre music and literature influenced hundreds or it may be only tens The effect is to be seen around us everywhere in daily life in a raising of the general cultural level Nor is individual performance likely to be seriously affected Photography and the gramophone were it was feared to put an end in turn to painting and music Both have helped the development of these arts and the understanding of their principles while as regards the individual executant they may possibly have eliminated a few who never would have attained perhaps even a mediocre competence

In a sense new inventions are the work of an individual yet in all but backward cultures the individual unless in exceptional instances is the spear head, while the general cultural level of society is the shaft of the spear The individual gathers up the threads of a general cultural trend This applies even in highly specialized branches of thought as for example when a whole body of scientific workers is proceeding along certain general but related lines of development Darwin was indebted to a general drift of philosophic and scientific thought and speculation which had been incubating for a generation or more before his time Only in the more primitive type of society existing in complete isolation could such conditions as Prof Hooton pictures prevail—a society in which innovation by an individual would be suppressed or adopted only with extreme reluctance by the conservative masses Cultural advance is usually a process of cross fertilization that overcomes by one means or another the natural conservatism which is undoubtedly a prominent feature in the make up of a primitive group The effects of such cross fertilization of cultures can be seen in the processes of growth of all the great civilizations of the Old World Of its advantages and disadvantages we are ourselves perhaps the most conspicuous example

What may be termed the humanization of future progress in a mechanistic world—a world in which as Western civilization spreads more and more widely to the peoples of less advanced culture mechanization will increase rather than diminish—is more likely to be brought about by a cross fertilization of the existing cultures of the different peoples of the world than by internal development of a nationalized ideal For while the nationalized ideal *ex hypothesi* is separatist in tendency it is only by a general pooling of ideals and ideas such as for example in the biological study of man which Prof Hooton rightly desiderates that we can hope to solve the problems threatening world civilization problems ranging from those of currency and the distribution of a food supply now running to waste to that which must be the pre occupation of us all the preservation of peace

Finally a word as to the biological study of man to which Prof Hooton would direct some of the creative energy now devoted to the interests of mechanization It is difficult to avoid the conclusion that in the application of scientific investigation to the problems of man s future and the planning of human relations—which must come if the world is not to drift into a worse chaos than that of the present time—the study of human heredity in all its aspects will play an important part How far the study of eugenics as at present pursued will enter into the attack on this problem is an open question Who is to decide what is the type to which to breed ? Further the prolifera tion of the alleged inferior classes of the population is after all only in accordance with Nature s method of ensuring in any species that out of an innumerable progeny the fit shall survive This is not an argument in favour of the physically and mentally degenerate but the history of English society is the last which should be called on to testify that the product of any one grade is inferior If however it is maintained that such an excess in numbers of offspring constitutes a social burden the argument is removed from the biological to a sociological plane and constitutes a problem of a different character

Dialectical Materialism in Biology

Biology and Marxism
By Prof Marcel Prenant Translated by C Desmond Greaves Pp xxiii + 223 (London Lawrence and Wishart Ltd 1938) 10*s* 6*d* net

MANY readers of NATURE will ask what Marxism has to do with biology It would be possible to write a volume on the economic influences which have done much to determine the course of biological research For example botany was at one time largely concerned with medicinal herbs The greatest age of systematic botany was that of the crude exploitation of Colonial floras and interest in plant genetics arose with the need for improvement in Colonial plants such as Canadian wheat and Javan sugar beet

But Prof Prenant s book is an attempt to apply to biology the principles of dialectical materialism the philosophy of Marx Engels and Lenin It was written for working class students to whom Marxism is already familiar and not primarily for biologists Nevertheless, every biologist who recognizes that Marxism whether true or false is an important philosophical movement will find the book extremely interesting

The author points out that Marxist ideas are peculiarly applicable in biology because both biology and Marxism are concerned with change and he is primarily concerned with evolution both individual and social Here Marx s and Engels criticism of Darwin whose results as a whole they accepted is of great interest In 1878 Engels wrote Darwin when considering natural selection leaves out of account the causes which have produced the variations in separate individuals and deals primarily with the way in which such individual variations gradually become the characteristics of a race variety or species On the other hand many biologists will consider the criticism of Darwinism quoted on p 194 less valid

It is particularly interesting to see how a modern Marxist tackles some of the outstanding problems of biology A Marxist must be *materialistic* without falling into mechanism and Prof Prenant certainly does his best to steer a course between the Scylla of epigenesis and the Charybdis of preformationism when discussing theories of embryonic development In his account of heredity while admitting the main results of the Morgan school he stresses the importance of the cytoplasm and above all the fact that at no time can the chromosomes be regarded as independent of their surroundings

In my opinion Prof Prenant under estimates the importance of selection for man It is true that natural selection in the strictly Darwinian sense of selective killing has been largely replaced by what Karl Pearson called reproductive selection based on differential fertility However under this new form selection is perhaps as important as ever and Dr Needham s critical notes show that there is plenty of room for divergence between Marxist biologists on quite fundamental questions

Indeed should interest in Marxism spread as appears to be probable there is no doubt that biological and other scientific problems will be more and more discussed from a Marxist angle That this need not involve any slavish acceptance of Marxist writings as gospel will be clear to any reader of Prof Prenant s statement (p 198) that in explaining life as an innate property of protein Engels was straying from the dialectical path Provided Marxists are willing to follow this example I do not think that non Marxist biologists need fear an attempt to impose Marxist dogmas on science such as probably occurred in some quarters in the Soviet Union between 1922 and 1932 and they may even admit that Marxism makes for a novel approach to certain problems which is bound to stimulate thought and experiment

The translation is almost uniformly excellent and the publishers may be congratulated on a book which will certainly interest Marxists in biology and should also interest many biologists in Marxism J B S HALDANE

Challenge to Ten

Duodecimal Arithmetic
By George S Terry Pp viii+407 (London New York, and Toronto, Longmans, Green and Co Ltd, 1938) 30s net

THIS handsome volume of tables is one of the most astonishing books ever composed by an enthusiast The practical advantages of twelve over ten as the base for everyday reckoning in any community which has progressed beyond counting on the fingers are obvious, and almost every language has a word for a dozen So far as the change from one base to another depends on the schooling of a single generation, it could be effected by a stroke of a governmental pen Unfortunately, ten dominates not only our habits but also our records, not only our present means of computation but also our inheritance of tables Converted to a belief in duodecimals by Emerson Andrews's 'New Numbers", and perceiving more clearly than many advocates that the issue is not theoretical, Mr Terry applied himself forthwith to the task of reducing the handicap by which any rival of the decimal system is delayed at the start, by providing a comprehensive collection of tables in the scale of twelve

As a practical man, Mr Terry begins with adequate tables for conversion between the scales of ten and twelve, but except in these tables the work is duodecimal throughout The tables include square roots of n and $12n$ and cube roots of n, $12n$ and 12^2n to 6 places from 12^2 to 12^3, reciprocals to 16 places as far as 12^3 9 place logarithms to base 12 at interval of $1/12^3$, natural logarithms, circular functions and their logarithms, exponential and hyperbolic functions, the exponential integral and the sine and cosine integrals the factorial function and its logarithmic derivative, and Bessel functions of orders 0, ½, and 1 Attention is paid everywhere to interpolability and the volume ends with a number of tables of interpolation coefficients

Some of the tables were calculated directly in the scale required, and some were obtained by the conversion of standard decimal tables In all cases, the ample margin of three places beyond those published was reserved, and the tables were differenced before being cut down The volume has been produced by reproduction of typescript this method eliminates many sources of accidental error, and is seen here at its best, the typist having evidently been aware of responsibility for the appearance as well as for the accuracy of the pages

Mr Terry's task could not have been performed more modestly, more efficiently, or with better judgment Nevertheless, such is the obstinacy of humanity that it is only too likely that when the millennium has come at last, five gross and eight more years must elapse before the universal adoption of duodecimal arithmetic E H N

Analysis of Explosives and Matches

Explosives, Matches and Fireworks
By Prof Joseph Reilly (Section of Lunge and Keane's "Technical Methods of Chemical Analysis", Second Edition Vol 4) Pp xi+172 (London and Edinburgh Gurney and Jackson, 1938) 7s 6d net

THE general arrangement of this work is the same as in the first edition of Lunge and Keane's treatise which was published in 1911, but the section on explosives, which previously was by the late Oscar Gutmann, has been rewritten entirely by Prof Reilly The directions in this section are clear and practical, and numerous references are given, so that the reader can obtain more detailed information Stability tests occupy twenty-four pages, and of these the Abel heat test takes seven, whereas the other forty-three methods dealt with have only seventeen pages between them In many cases only the general character of the test has been given, but as the chemical practitioner will seldom be called upon to carry them out, this is no doubt sufficient

The sections on matches and fireworks in the first edition were written by Dr A Bujard, of Stuttgart, and the English translation was revised by E G Clayton Prof Reilly has rewritten most of the earlier parts, dealing with woods and waxes for matches, phosphorus and the composition and manufacture of glue, but the rest of the matter is almost unchanged since 1911 Of the fifty-one and a half pages devoted to matches twenty-five deal with glue and other binding substances

Nearly all technical works dealing with fireworks are unsatisfactory, and that of Bujard and Clayton was no exception It is therefore to be regretted that the section has not been rewritten On p 149 are given some coloured fire mixtures containing potassium chlorate and sulphur, and there is a green star mixture specially recommended by Clayton containing realgar as well On p 151 Prof Reilly has added the words "The use of chlorates is restricted in mixtures on account of their sensitiveness and has been made illegal in some countries " This is too mild as mixtures containing chlorate together with sulphur or a sulphide have been forbidden definitely for fireworks since 1894 in Great Britain and are classified as fulminates" If one of the ingredients be sulphide of arsenic (realgar) the composition is specially dangerous Many fatal accidents have been caused by such fireworks

Mercury fulminate and detonators are dealt with twice—in the explosives section and again in that dealing with ' Primings and Fireworks"—but the word fulminate" does not occur in the index, and against mercury fulminate ' there is only reference to the fireworks section The latter contains a description of the Esop test for detonators which is inaccurate and confused

The first two thirds of this book are very satisfactory but unfortunately this cannot be said of the remainder A M

General Scientific Knowledge

Van Nostrand's Scientific Encyclopedia
Pp v + 234 (London Chapman and Hall, Ltd, 1938) 50s net

THIS encyclopædia is stated to cover the basic sciences of chemistry physics mineralogy, geology botany, astronomy, and mathematics and the applied sciences of navigation aeronautics and medicine and the three branches of engineering, civil, mechanical and electrical To do this even when as many as 10,000 separate articles each of between 100 and 1,000 words are allowed, necessitates a good deal of selection, abbreviation and omission The authors and publishers plead, in the preface, for indulgence for such omissions, they write "The exercise of judgement in the selection of material was unavoidable and it was necessary to maintain a limit of difficulty beyond which it was impracticable to go in attempting to cover so broad a field within the physical confines of one useful volume " To grant this indulgence seems but just

The information given is, on the whole accurate and trustworthy, but in some instances the obligatory brevity may give the reader a wrong impression, and occasional statements are, to say the least, controversial Each little article is logically written, beginning with a simple definition which is afterwards developed, and the more complex concepts are then discussed Every term explained in the volume is printed in bold type wherever it is used significantly in the course of articles on other terms This system of cross reference is a useful and helpful feature of the book No provision, however, is made for those who wish to pursue a subject further, a few references to standard works might have been included at the end of the more complex articles True, there would be difficulty in selecting suitable references but the authors have had to exercise their powers in this direction throughout the preparation of the whole work

The authors are all associated with American academic institutions, and naturally American practice and views are reflected in many of the articles The responsibility for each science has been left largely in the hands of a single author for the sake of unity, but in each instance a number of others has worked with the author and a group has acted in an advisory capacity

In a work of this nature, some inconsistencies are bound to occur for example some three pages are devoted to an article on chemistry, but no entries at all are to be found under such headings as physics" biology ' or medicine ' some indication of the scope of these subjects might have been given with suitable cross references Despite all that is often said about the absurdities of placing the different branches of science in water tight compartments it is still necessary to define their scope both for academic and for economic reasons Each university authority appears to have clear notions as to the dividing line between various branches of science, although they are not always in common agreement Again, admission to membership of the various professional scientific and engineering bodies normally involves the decision of some committee as to whether a man is a chemist, physicist, electrical engineer and so forth, and cases are frequent when a man is elected to several such bodies, demonstrating his versatility or may be the difficulties of dividing science into professional groups Whilst for many purposes several such individual organizations are advantageous, one representative and respected body able *and willing* to speak for science as a whole, and perhaps also engineering, is likely to achieve more There appears to be a growing desire to have such a body, as the recent activities of the British Association for the Advancement of Science has proved But this is digressing—the point to be stressed is that the boundaries of the various branches of science have been defined and some indication of these definitions artificial and changeable as they may be should in the reviewer s opinion have been included in such an encyclopædia It is interesting to find NATURE and the *Philosophical Magazine* are classified on p 249 under *chemical* journals while the Royal Society heads the list of chemical societies !

The printing is excellent and is in double column with clear headings The illustrations are clear and helpful and some pleasing coloured plates are included The book is well produced and considering its 1 200 pages is not too bulky for convenient handling It will form a valuable addition to the libraries of teaching institutions and be of considerable help to those private individuals who can afford it requiring a reference book of science H R L

Gulf Coast Oilfields

Gulf Coast Oil Fields
a Symposium on the Gulf Coast Cenozoic Edited by Donald C Barton and George Sawtelle Pp xxii+1070 (Tulsa Okla American Association of Petroleum Geologists London Thomas Murby and Co 1936) 4 dollars 18*s* 6*d*

AT the Houston convention of the American Association of Petroleum Geologists held in March 1924 an attempt was made to give a comprehensive picture of American salt domes Papers included descriptions of oilfields theories as to their origin and a general summary of research carried out to that date In 1926 these papers were published by the American Association of Petroleum Geologists in the form of a symposium entitled Geology of Salt Dome Oil Fields

Since that time a wealth of new information and discoveries concerning Gulf Coast geology has come to light In fact developments during the intervening decade have been far more rapid than during the quarter century which preceded publication of the original volume At the 1933 convention of the Association at Houston a series of papers was presented which reflected the trend of progress at that time and these have formed the nucleus of a further volume under the above title recently published Other important papers have been added to make the whole symposium representative of what is in reality a new era of Gulf Coast geology

The work comprises in all forty four papers grouped under three headings general and theoretical papers stratigraphy descriptions of oilfields and salt domes The last group is subdivided into four regions South Texas South east Texas Southern Louisiana and East Texas An unusual frontispiece to this book is a mosaic of parts of forty aero photographs taken at heights of approximately 12 000 ft of Barbers Hill Salt Dome Chambers County Texas to facilitate accurate reading of this frontispiece the significance of various elements of the picture are indicated and instruction given in the correct interpretation of this and similar aerial photographs

D C Barton points out in a foreword to the volume that application of geophysical methods of prospecting was largely responsible for the incidence of the new era of Gulf Coast history Half way through the period under review the number of known domes had been doubled by torsion balance and seismograph discoveries and an intensive refraction campaign was being conducted Then after a short lull due to economic depression to the flood of oil from East Texas and decline in geophysical successes three important discoveries in Texas and Louisiana confirmed the theory that deep dome structures are more prolific than shallow ones and easier to prospect The rate of exploration afterwards became the fastest in the history of the Gulf Coast The area of potentially good production was vastly increased production zones were deeper and the depth of drilling almost doubled In 1924 production of crude oil was 30 million barrels In 1934 it was 94 million barrels and in the first half of 1936 25½ million barrels were produced from southern Louisiana alone

It seems almost impossible that this rate of progress should be maintained but D C Barton predicts some interesting developments in the coming decade Of these perhaps the most spectacular is that wells to a depth of 20 000 ft or more may be mechanically feasible and not commercially impracticable Moreover in his view there will be progressive improvement in geophysical technique with the possibility of detecting commercial accumulations of oil and gas by direct method and prior to drilling though probably not at great depth Increased efficiency in recovery of crude oil from sands increased production of gasolene kerosene and diesel oil from a given quantity of crude oil conversion of natural gas into gasolene by polymerization and increased efficiency in the consumption of petroleum products as motor fuels will all combine to make the next decade as prosperous as the one that is just past

An Introduction to the Scientific Study of the Soil

By Prof Norman M Comber Third edition Pp vii + 206 (London Edward Arnold and Co, 1936) 7*s* 6*d* net

WHILST no outstanding changes have been made in the third edition of Prof Comber s deservedly well known book its subject matter has been brought fully up to date without sacrifice to the conciseness and clarity of the original text The book is intended for agricultural and horticultural students, that is, those whose interest in the soil has a strong practical bias, nevertheless, the scientific point of view is maintained so consistently in each chapter that the student is led to think of the soil as much from the pedological as from the purely practical point of view Indeed, the greater part of the book is concerned with the study of soil as a natural entity quite apart from the problem of its agricultural utilization It is perhaps the chapters dealing with the main facts of soil physics and soil chemistry that help the reader most to bridge the apparent gap between the scientific and the practical approach to the study of soil

The scientific point of view from which the book is written is typified in the title of the penultimate chapter on The Artificial Treatment of the Soil", in which the effects of common cultivation practices on soil fertility are briefly reviewed In this section a useful account of the replicated plot system used in modern field experiments is also given The chapter on soil water is a good example of the author s facility in stating main facts and definitions, which are apt to be lost sight of in the more advanced literature of soil science Useful advice on how to use the latter is given at the end of the book, but in the text itself there are practically no references to the sources of the works which are quoted The inclusion of such references would be surely welcomed by what Prof Comber describes in his preface as botanists, ecologists and others besides agricultural students , who are partly responsible for the demand for a third edition of this extremely useful book

A J L L

The Organisation of Agriculture

with Applications to South Africa By Prof Hubert D Leppan Pp v + 83 (Johannesburg Central News Agency, 1936) 4*s*

ONE of the most urgent of many tasks confronting South Africa is to save the soil The causative evils most frequently cited are faulty pasture management, particularly overstocking, and cultivation of unsuitable land Behind these lie racial, social and political causes that have influenced the development of South African agriculture A complete re organization of agriculture is now imperative

Prof Leppan considers that in a policy of land utilization concentrating almost entirely on properly organized animal husbandry lies South Africa's chief hope of salvation He traces the past policy of encouraging cereal production, assisted by export subsidies, tariffs and a magnificent elevator system, to the economic consequences of the South African War, and points out that the reverse policy of encouraging cheap grain imports would have the effect of increasing soil fertility, thereby helping to save the veld from erosion The imported feeds would be used to relieve pressure on the pastures, and not to carry more animals, which should be fewer and of better quality More use should be made of cultivated land in producing animal rather than human foods The meat market could be enormously extended and the demand for maize proportionately reduced, by educating the natives and raising their standard of living

Prof Leppan considers that the land in South Africa is overstocked with men as well as with animals and that a white peasant class is undesirable in South Africa He recommends fostering urban activities to relieve pressure on the land and the State purchase of derelict farms which might be rented on long leases with due safeguards against overstocking and other maltreatment All economic and political measures, however are useless unless they are supplementary to controlled veld management

G V J

The Physical Basis of Geography

an Outline of Geomorphology By Dr S W Wooldridge and R S Morgan (University Geographical Series) Pp xxi + 445 (London New York and Toronto Longmans Green and Co 1937) 12*s* 6*d* net

IN the first part of this book, the authors have deliberately taken sides, in an endeavour to place much debated topics in geophysics and tectonics clearly before the student For example Wegener s continental drift theory is presented in a much more favourable light than customary No harm will be done to the student by this method of treatment provided he realizes that he is receiving one point of view Incidentally it is pleasant to see that regrettable term betwixt mountains somewhat frowned upon

The second and more important part of the book has a different tone Here the central theme is the cycle of erosion as conceived by W M Davis and elaborated and modified by Johnson and others The development of landscape under many environments is critically discussed in the light of the orderly sequence of this cycle Examples of the chronology of denudation, as for example in the Appalachians and the Weald, are fully described Marine erosion, arid erosion, and erosion in limestone regions are considered Under this last topic there is given a full account of the development of the land forms of the chalk in Great Britain—forms in their way as remarkable and as interesting as those of the more fashionable Dalmatian Karst The book closes with a critical discussion of the influence of glaciation upon scenery, in which the views of the erosionists and protectionists are fairly presented, and with a short account of the possible part played by glacial control in certain major physiographic effects of the Ice Age.

This book, and especially the more important second part of it, should be read by geographers and geologists alike, as it is a sound and critical exposition of erosion processes

Arctic Harpooner
a Voyage on the Schooner *Abbie Bradford*, 1878–1879 By Robert Ferguson Pp xii+216 (Philadelphia University of Pennsylvania Press, London Oxford University Press, 1938) 9*s* net

MR L D STAIR, evidently with great care, has converted the diary of Robert Ferguson into a narrative It is certainly a readable book, but there is at times the slightest uneasiness in the reader's mind lest the editor may have been carried away by his theme the feeling is probably unjustified Matters of precise interest are (*a*) the accounts of the Eskimo and of Ferguson's success on his land journeys, short though they were due to adopting completely the native mode of life, long before Stefansson, and (*b*) the information regarding the Greenland whale, at that time *the* whale

Ferguson mentions a whale about 95 ft long, this can scarcely be correct since the Rev William Scoresby, D D, F R S, considered 65 ft unusual and 70 ft the absolute limit of size for this species On the other hand, Ferguson's figure of 130 barrels for this individual seems surprising, but the careful Scoresby measured a whale of 52 ft which gave 24 tons of oil and says that whales yielding 20 tons of oil are by no means uncommon' and whales have been caught that afforded nearly 30 tons of pure oil He states further that the ton or tun of oil is 252 gallons wine measure', this is still the basis of the barrel of whale oil, which is reckoned in round figures at 40 gallons or 6 barrels to the ton These whales therefore gave 120–180 barrels, which would be most remarkable for the gigantic Blue whale of the South It should be mentioned on Scoresby's authority that the blubber of the Greenland whale is from 8 or 10 to 20 inches thick

J E HAMILTON

Industrial Chemistry
an Elementary Treatise for the Student and General Reader By Prof Emil Ramond Riegel Third edition Pp 851 (New York Reinhold Publishing Corporation, London Chapman and Hall, Ltd, 1937) 28*s* 6*d* net

PROF RIEGEL'S book provides an admirable survey of modern industrial chemistry which is suited to the needs of the student and the general reader The various sections have been written with the collaboration of experts and give in a concise form a wealth of authoritative information The topics include mineral acids and alkalis, nitrogen products, phosphates, fertilizers, cements, ceramics, glass, fuels, water, coal products, electrothermal and electrolytic processes, petroleum, and the important organic chemical industries such as the manufacture of dyes, pigments, oils, explosives, rubber, etc There are also good chapters on chemical plant and instruments of control, and on the metallurgy of iron and steel, copper and other common metals, and on the platinum metals and radium The treatment is sufficiently detailed to be really useful, and the book is well illustrated and indexed There are references to standard treatises and to recent articles in journals—the latter mostly American

Physikalische Methoden im Chemischen Laboratorium
Pp v+267 (Berlin Verlag Chemie, G m b H, 1937) 3 60 gold marks

DURING 1936–37, a series of thirteen articles on the application of new physical methods to the solution of chemical problems appeared in the German technical journal *Angewandte Chemie* these have now been reprinted and collected in the book under review The subjects treated are X ray methods, ultra sonic waves, chromatography (three articles), Raman effect, dielectric loss, spectrum analysis (two articles), polarographic methods (two articles), photo electric spectrophotometry, and colorimetry with colloidal solutions Some of the articles, for example, those on the application of X ray methods and of ultra sonic waves, are mainly concerned with a description of the results obtained, but in others, as those on chromatography and the polarograph, adequate experimental details are given The authors of the various sections have had practical experience of the subjects about which they have written, and so the matter may be regarded as authoritative, although as is to be expected the style is not uniform Altogether the compilation should prove of considerable interest to chemists who wish to become acquainted with some of the recent developments in experimental technique The book is well produced, in spite of its paper covers, and is excellent value for its relatively small price

S G

The Modern Mind
By Michael Roberts Pp 284 (London Faber and Faber, Ltd, 1937) 8*s* 6*d* net

THE special interest of this brilliant and well written essay is the development given to the view that the history of thought shows that there are attitudes of mind corresponding to various historical periods, and that so far as the English mind is concerned, such attitudes are evolutionary products involving the intuitions and inhibitions of our medieval ancestors This is coupled with the author's effort to re establish truth as poetry and religion apprehend it, though he seems to think that poetry and religion have no concern with facts at all In the exposition of these views, the author displays great learning and a gift for discovering striking analogies However controversial some of his conclusions may be, the reading of his book will be found to be both beneficial and pleasant

T G

A Scheme of Inorganic Qualitative Analysis
By Dr E M Stoddart Pp vii+39 (London William Heinemann, Ltd, 1937) 1*s* 6*d*

THIS small manual contains some useful tables for group separations and confirmatory tests. By omitting equations, which the student can find in the text books of inorganic chemistry, it has been possible to get the material into a small space, convenient for bench use, and to produce an inexpensive guide to qualitative analysis The book is very clearly written and should prove useful in school and college laboratories The standard is that of the London Intermediate and General B Sc

Foundations of Physics

By Prof. A. S. Eve, C.B.E., F.R.S.

THE relative fields of physics and metaphysics, and the relation of theory or speculation to experiment in the pursuit of natural knowledge, have been the subject of several contributions to NATURE in recent months In May of last year, under the title of "Modern Aristotelianism", Prof. H Dingle presented Aristotle and Galileo as examples of opposing schools of thought in a discussion in which the main question raised was "whether the *foundation* of science shall be observation or invention". A month later, NATURE published a special Supplement containing communications from many leading scientific workers on the desirable balance to be maintained between observational methods and deduction by pure reasoning from speculative assumptions One aspect of this wide subject was developed further in a discourse on "Science and the Unobservable" delivered by Prof. Dingle at the Royal Institution and published as a Supplement to NATURE of January 1 of this year; and this was followed by two articles by Dr Harold Jeffreys on "Science, Logic and Philosophy" in the issues of April 16 and 23, dealing with relationships between what is understood as idealism and realism. A week later, in an article entitled "The Pragmatic and the Dogmatic Spirit in Physics", Prof J. Stark attempted to divide physics into two groups or tendencies; and at the same time made an unpardonable attack on the Jewish people in general and Einstein in particular The article was based upon a communication made by Prof Stark to *Das Schwarze Korps* in connexion with the movement to purge German science of Jewish influence and was contributed to NATURE by invitation of the Editor in order to obtain an authoritative statement from Germany upon what this influence was supposed to signify.

Prof. Stark's article has been met with cold disfavour by the generality of physicists, who have made no reply to it, deeming that the statements in question carried with them their own refutation so obviously that no answer was required. There was, however, another reason for this silence. Men fear to pour oil, not on troubled water, but on a blazing furnace, which if left undisturbed, might reach exhaustion by its very violence. Yet it may be desirable not to let the case go by default, but to avert strife and discord by an examination of the true state of affairs.

Early in the nineteenth century, Fourier in his "Analytical Theory of Heat" stated the principles which guide us in our scientific outlook

> "Primary causes are unknown to us; but are subject to simple and constant laws, which may be discovered by observation, the study of them being the object of natural philosophy." He then referred to the triumphs of Galileo and Newton, where so many great effects follow from so few causes, and then continued, "but whatever may be the range of mechanical theories, they do not apply to the effects of heat These make up a special order of phenomena, which cannot be explained by the principles of motion and equilibrium. . . . Profound study of Nature is the most fertile source of mathematical discoveries. . . . There cannot be a language more universal and more simple, more free from errors and from obscurities, that is to say more worthy to express the invariable relations of natural things. Considered from this point of view, mathematical analysis is as extensive as Nature itself, . . . its chief attribute is clearness; it has no marks to express confused notions. It brings together phenomena the most diverse and discovers the hidden analogies which unite them"

No apology is needed for quoting Fourier—a man who combined observation and theory, and found relations which, to so great a degree and in so many cases, could represent what we believe to be as close an approach as is possible to natural phenomena, which we sometimes rather vaguely call reality.

There are to-day no physicists who do not seek and encourage tests by experiments and observations in order to verify, modify or reject their ideas and theories Thus, Rutherford said that it would be time to abandon the theory of radioactivity (at first strongly opposed by some great authorities as a most revolutionary idea) as soon as a single, definite, experimental result contradicted it. Einstein actually named and described three fundamental observational results which, if not verified, would necessitate the abandonment of his theory of relativity Is this dogmatism ? Consider, too, how that theory arose The test experiments of Michelson, Morley and Miller had failed to indicate the swift motion of the earth through the "luminiferous æther" and it was necessary to revise Newtonian mechanics and to bring them into harmony with electromagnetic theory. The efforts of Fitzgerald, Larmor and Lorentz indicated a road which, extended and widened, enabled Einstein to enunciate his great principles of special and general relativity. The experiments of Kaufmann and Bucherer showed that the masses of electrified particles increased with high velocities an idea never contemplated by Newton The relation between energy and mass the greatest result of our times largely due to Einstein has received confirmation in the balance sheet of energy in nuclear transformations In the field of statistics the Bose Einstein relation takes high rank in physics with its counterpart the Fermi Dirac Nor must we allow prejudice to blind us to the fact that Einstein received his Nobel prize for his discoveries apart from relativity and indeed his photo electric relation is one of the most fundamental in the realm of atomic physics[1]

The history of science is full of remarkable chains of which successive discoveries are the links Thus Rutherford surmised the existence and stated the properties of the neutron in 1921 Four years later Chadwick was writing that the time had come to make a determined search for it—a search which was made in vain until the Curie Joliots obtained strange and unexpected results when bombarding beryllium with alpha particles and Chadwick then saw his goal in sight Would Rutherford be termed pragmatist or dogmatist in 1921 ?

An equally remarkable development came from Faraday s researches His work on electrolysis needed no development it was simple and complete Not so his work on induction which required the mathematical genius of Maxwell to bring it to fruition by his remarkable conception of an electric displacement current in regions devoid of matter surely a conception as revolutionary as any of our modern ideas The whole electromagnetic theory was born and the relation between electricity and light established Ten years after the death of this great physicist who blended theory and practice in the highest degree Hertz started his remarkable and successful investigations on the production of electromagnetic waves and these radiations were explored by a host of able workers until eventually Marconi achieved his triumphs with far flung radio messages

A more remarkable chain of discovery is that which originated with Planck who found it *inevitable* to believe that energy passed between atoms as quanta proportional to their frequencies and thereby succeeded using the most revolutionary idea of our times in a rational theory where Wien, Rayleigh and Jeans had in part succeeded, but then met with insurmountable obstacles To-day Planck s constant takes a permanent place in physics with other fundamental constants such as the mass of a hydrogen atom the electronic charge or the velocity of light There must be many who remember the staunch resistance that the quantum theory in its early days met from many most distinguished men of science who to day accept it as part of the ordinary nature of things—but who dares to say that he understands it ? How rash it would be at any time to trammel or despise those who are working on the fascinating borderline of the known and the unknown

In due course Bohr was able to blend the idea of quanta with the electrons around the Rutherford nucleus and to obtain a remarkable theory of radiations for hydrogen ionized helium and for X rays connected with the inner rings of the heavier atoms His marvellous theory still the background of the periodic table and spectral analysis showed signs of cracking in 1925 when applied to numerous cases of atomic radiation A way out of these serious difficulties has been found by L de Broglie Schrodinger Bohr Heisenberg Dirac and others The problem was one of the most difficult ever presented to the human mind

It was the many bodied problem complicated with electric charge spin and magnetic moment Complete failure might well have been anticipated but the remarkable sharpness of many spectral lines even when powerful magnetic or electric fields were applied by Zeeman or Stark showed that there was some ordered simplicity in apparent chaos Following the lead of experimental results certain rules were formulated so that equations were found showing something in the nature of standing waves which indicate the probable position of the electron at any time These equations approach reality in the sense that they give the right answers ! It is as though a man used logarithms without understanding the theory underlying them

The fact that physical interpretation lags far behind the mathematical calculation (which are nevertheless based on experimental results) in no wise detracts from the work of these men of genius who belong to various nationalities If these men are to be deemed dogmatists then it would indeed be an honour to be included in their ranks But the whole theory of pragmatists and dogmatists is pure moonshine and to link such discoveries mainly with the Jewish people is a poor compliment to the rest of mankind

A more just estimate of the true situation is that due to Maurice Duc de Broglie who wrote in NATURE of May 7 1933

> Recent theoretical views suggest that a mechanistic view of Nature cannot be pushed beyond a certain point, and that the fundamental laws can only be expressed in abstract terms, defying all attempts at an intelligible description The philosophy of science has always swung between these two points of view The work of the great physicist [Rutherford] to whom these lines are dedicated shows however to what brilliant discoveries the method followed by Lord Rutherford can lead '

There are nevertheless many great leaders notably Bohr who believe that we are still merely approaching the problem and that in due course the reasons for the correctness of the quantum theory and wave mechanics will be made clear This further step if it is ever achieved will not detract from the fame of the present pioneers At least it has been made certain that novel ideas due to many great men of science often revolutionary in type have first been scorned and later accepted but there has certainly never been any necessity for what has been called advertising Let us name Copernicus Galileo Newton Fourier Maxwell Planck Rutherford Bohr Einstein Other names might be added of men whose just fame is not yet so firmly established men belonging too to various nationalities— a matter of no real importance in science

Rutherford indeed frequently lectured on his discoveries to a variety of audiences in many countries all over the world He believed that it was one of his duties to interpret and spread the good news of scientific discovery and progress He would be a rash man who dared to use the word advertising in this connexion and no fair minded man will connect the word with Einstein for his views quickly and naturally caught and held the attention both of the well informed and the general public

Although Rutherford made no incursions into wave mechanics and held fast wherever and as long as he could to classical views yet he was honest enough to admit when the latter failed and he was eager to adopt anything however modern or revolutionary its source which might assist him in his research work such as the use of resonance to secure low voltage transmutation an idea due to Gamow and to Condon and Gurney (1928) derived from wave mechanical theory and impossible from a classical viewpoint We must also admire that abstruse analysis of Dirac involving negative energy which led him to the conception of a positive electron before its discovery in cosmic rays by Anderson and its confirmation by Blackett Here as in so many cases ideas which might be termed dogmatic by some have led directly to the pragmatic In fact theory based on experiment or observation (and who bases it on anything else ?) will often yield results at first unexpected just as Faraday s experiment led through Maxwell s theory to wireless telegraphy telephony and broadcasting on one hand and to our gigantic power houses and electrical supply on the other

That is the gist of the whole matter and there is nothing more to be said The search for truth or reality is common to all but there may be different avenues of approach Let us throw these open without hindrance and give full credit to all who extend by any means our natural knowledge setting aside all prejudices and determined that the rule of reason and the law of liberty shall prevail throughout the realms of science

Sir William Herschel, 1738-1822

By Sir Frank Dyson, K B E , F R S

At the age of thirty five years William Herschel a distinguished and prosperous musician was impelled to explore the heavens He found a small telescope which he had hired insufficient for his needs and with great skill and patience constructed larger and larger instruments After his day s work, he spent a great part of the night observing the stars The conclusions he drew from his observations were characterized by an originality boldness and splendour of outlook which have placed him among the greatest astronomers We ought he writes to avoid two opposite extremes If we indulge in a fanciful imagination and build worlds of our own we must not wonder at going wide from the path of truth and nature On the other hand if we add observation to observation without attempting to draw not only certain conclusions but also conjectural views from them we offend against the very end for which observations ought to be made I will endeavour to keep a proper medium but if I should deviate from that I would wish not to fall into the latter error

Frederick William Herschel was born at Hanover on November 15 1738 His father was a hautboy player in the Hanoverian Guards and at the age of fourteen William was engaged as a musician in that regiment He left in 1757 as he had taken no oath binding him to military service He received a formal discharge in 1762 The legend that he deserted from the army and received a pardon from George III in 1782 is a fiction

Towards the end of 1757 Herschel came to England and for some time had hard work to earn a living by copying music and giving occasional performances His musical abilities were gradually recognized, and in 1760 he was appointed instructor of the band of the Yorkshire Militia stationed at Richmond In 1762 he resigned this post he composed symphonies, conducted concerts at Leeds, was for a short time organist of the Halifax parish church until in 1766 he became organist at the Octagon Chapel at Bath He was soon the centre of musical activity in this fashionable watering place and had a busy life, composing conducting concerts and taking pupils

As music was not sufficient for his boundless energy, Herschel studied Italian, Greek harmonics, mathematics, optics and astronomy In 1773, he hired a small telescope and commenced to search the heavens He soon wanted a larger telescope, and after many experiments and failures succeeded in making a Newtonian reflector of six and a half inches diameter and seven feet focal length The parabolic mirror was of speculum metal in the proportion of 5 lb of tin to 9 lb of copper He cast the disk himself ground it and polished it with his own hands With this instrument, he repeated and extended a previous survey of the heavens His intention was to find bright stars with faint stars near them on the supposition that the difference of magnitude was the effect of distance and might thus serve to determine stellar distances

On March 13 1781 Herschel made this entry in his note book In the quartile near ζ Tauri, the lowest of the two is a curious either nebulous star or perhaps a comet After several cloudy nights, he found on March 17 that the star had moved and was presumably a comet He communicated his discovery to Maskelyne the Astronomer Royal who wrote to him on April 23 "It is as likely to be a regular planet moving in an orbit nearly circular round the Sun as a comet moving a very eccentric ellipsis I have not seen any coma or tails to it" The evidence of its great distance and uniform movement soon showed that the body was, in fact, a new planet This was an astounding discovery, as no one had ever imagined there could be more than the five planets Mercury, Venus, Mars, Jupiter and Saturn, which had been known for ages Herschel was awarded the Copley Medal of the Royal Society in November 1781 and was elected a fellow of the Society in December

The attention of George III was directed to the fame of the Hanoverian astronomer, with the result that Herschel was appointed King's Astronomer with a salary of £200 a year He was now relieved of the necessity of snatching astronomical observations in the intervals of concerts or sitting up all night after a hard day's work He had at this time a 7 foot telescope of 6 inches aperture and a 20 foot telescope of 12 inches aperture He now proceeded to make a 20 foot telescope with an 18 inch speculum, and commenced his famous 'sweeps' to find what was in the sky and to gauge the depths of the heavens Some years later, he constructed the great 40 foot telescope with a 40 inch speculum Before he had made the flat mirror so as to use the telescope in the Newtonian form he looked down the tube directly with his eyepiece and found the definition good, and the brilliancy greater owing to the absence of a second reflection He accordingly adopted what is known as the 'Herschelian" type of reflecting telescope in later work

Herschel continued his observing with, if possible, increased vigour, finding in his 'sweeps' objects which enrich the natural history of the sky and classifying them according to their species, hundreds of double stars, thousands of clusters and nebulæ Double stars attracted him because he hoped to find a parallactic displacement between a bright star and its faint neighbour, and thus obtain an idea of stellar distances He published a list of 269 double stars in 1782, giving their position angles and their angular distances apart inferred roughly from the size of the disks In 1784 he published a further list of 484 stars, with their distances apart now measured by a micrometer He seems to have suspected that some of them might be real binary systems By 1802 he was satisfied from the changes in position angle that a considerable number of these stars were binary systems moving in elliptic orbits under their mutual gravitation Newton's law thus held in these distant regions in space

In 1760 Mayer had indicated the perspective effect which would be shown in the proper motions of stars by the movement of the sun in space, but had failed to find it In 1783, from the proper motions of seven bright stars given by Lalande, Herschel determined that the sun was moving in the direction of λ Herculis From a larger number of stars he obtained a slightly different and not quite so good a direction as that found by later researches from thousands of stars arranged in all manner of ways according to magnitude size of proper motion, and type of spectrum

Herschel's ideas about the physical nature of the sun now seem to us very extraordinary He regarded it as a dark, cool, solid globe, possibly inhabited, protected by a layer of cloud from the light and heat of the upper luminous region This solid part of the sun is revealed in the openings of the luminous region shown in sun spots This theory held the field for many years Erroneous facts are harmful, but erroneous theories are better than none at all and act as incentives to better ones

With his large telescopes, Herschel examined the planets He discovered two satellites revolving around Georgium Sidus' or Uranus, and thus encouraged found two additional satellites of Saturn He found that Venus was covered with clouds, noticed the changes in the white spots at the poles of Mars, and concluded that Mars was most like the earth as regards habitability He determined the direction of the axes, periods of revolution and oblateness of the planets He found that a spot in the atmosphere of Jupiter had a different period of revolution from the rest of the planet

Herschel's name is inseparably associated with great telescopes, but for the years 1795–97 he interrupted his work to arrange the stars in different constellations, according to their magnitudes This was largely done with the naked eye The work was not estimated at its full value until Prof E C Pickering reduced and discussed the observations Herschel furnished observations of nearly 3 000 stars from which their magnitudes a hundred years ago can be determined with an accuracy approaching that of the best modern catalogues '

Herschel was attracted by Messier s short list of nebulæ and clusters published in the *Connaissance des Temps* for 1783 In the belief that all nebulæ could be resolved into stars he commenced a survey of the whole sky with his new 20 foot reflector of 18 inches aperture At the same time, by counting the number of stars in equal areas in different parts of the sky, he purposed to 'gauge' the depth of the sidereal universe He began these famous 'sweeps' of the heavens on October 28, 1783 He first placed his telescope in the meridian and standing in a gallery at the end of the telescope could give it a motion in azimuth of 10° or 12° either way He moved the telescope slowly backwards or forwards and noted what he saw He then changed the telescope 8′ or 10′ in altitude Twenty or thirty of such operations he called a 'sweep' They were very fatiguing and spoiled the sensitiveness of his eye for faint objects After the forty first sweep he discarded this method and had recourse to vertical sweeps, employing a workman to move the telescope, and calling out his observations to his sister Caroline, who noted them down In 1789 he published a catalogue of 1,000 clusters and nebulæ "As a mere explorer of the heavens," wrote Agnes Clerke, "his labours were prodigious He discovered no less than 2,500 Nebulæ, 806 double stars, and passed the whole firmament in review four several times, and counted the stars in 3,400 *gauge* fields "

In these 'gauges', Herschel counted the number of stars in the field of view of his eyepiece, which had a diameter of 15′ His telescope revealed all the stars to about the fourteenth magnitude, at least a thousand times as faint as the faintest star visible to the naked eye He found that the number of stars diminished with increasing distance from the Milky Way until they were only one thirtieth of the number at its pole He was thus led to the 'grindstone' theory of the 'Construction of the Universe His views were modified in his later papers in 1811 and 1814 and he realized that the Milky Way is more complex and that nebulæ are not always irresolvable clusters "We may have surmized nebulæ to be no other than clusters of stars disguised by their very great distance but a longer experience and better acquaintance of their nature will not allow of such a principle " He gave the name "planetary nebulæ ' to bodies which, notwithstanding their planetary aspect retain a haziness by which they are surrounded and evinces their nebulous origin " He regarded the Orion nebula as true nebulosity and typical of other extended nebulæ, but retained his belief that some nebulæ were resolvable into stars and were comparable in size with our own Galaxy

Only the briefest reference can be made to an important paper published in 1800, when he discovered that the heat derived immediately from the sun or from candescent terrestrial substances is occasioned by rays emanating from them, and that such heat making rays are subject to reflexion and refraction He gives in a diagram the intensity of the heat in what we should now call all wave lengths extending from the infra red to the violet

We must on no account overlook the help Herschel received all his life from his devoted sister Caroline From 1772 she was his constant companion, housekeeper and assistant in his music and astronomy She accompanied him to Slough and would sit up whole nights taking down his observations and copying them out the following day When William married she took lodgings in Slough and still continued as his assistant At her brother's suggestion, she searched for comets and discovered no fewer than eight After Herschel's death she returned to Hanover and prepared a catalogue of 2,500 nebulæ and clusters discovered by him For this she was awarded the Gold Medal of the Astronomical Society She died in 1848 after a prolonged and cheerv old age

On May 8, 1788, Herschel married Mary, daughter of Mr Adee Baldwin, a merchant of the City of London, and widow of John Pitt, Esq Their son John was born on March 7, 1792 Mrs. Herschel was of an amiable and gentle character and lived on friendly terms with Caroline, whom she had displaced In 1791, Herschel visited Glasgow and was given the freedom of the City and a doctorate of laws by the University, and on his return called on Michell, an astronomer of distinction and originality In 1802 he went to Paris and met Messier Delambre, Laplace, Count Rumford and Napoleon In 1816 he was knighted by the Prince Regent In 1820, when the Astronomical Society was founded, he was made its first president He was too feeble to attend the meetings, but allowed his last paper to be published in the Memoirs of the Society He died at Slough on August 25, 1822, and was buried in the Church of St Lawrence at Upton *

---

* In the preparation of this article I have used to a great extent the admirable introduction to The Scientific papers of Sir William Herschel written by Dr Dreyer and am also indebted to a conversation with Dr W H Steavenson —F W D

Obituary Notices

Sir Robert Mond, F R S

ROBERT LUDWIG MOND the elder son of the late Dr Ludwig Mond F R S, was born at Farnworth, near Widnes Lancashire, on September 9 1867 and was brother of Alfred Moritz Mond the late Lord Melchett He was educated at Cheltenham and at Peterhouse, Cambridge Later he worked at the Polytechnicum Zurich, and at the Universities of Edinburgh and Glasgow, and had the privilege of being private assistant to Sir William Thomson (Lord Kelvin) His first wife the mother of his two daughters died tragically in Egypt in 1905 and he married in 1922 Marie Louise Le Manach of Belle Isle en Terre Brittany

In consequence of his varied training in the physical sciences and the atmosphere of his home Robert Mond had an extraordinary wide outlook on scientific problems so that while never becoming a specialist in any one branch he was able to contribute materially to the solution of problems in these subjects On proceeding to Winnington he had the privilege of working not only with his father but also with such distinguished collaborators as Carl Langer and Friedrich Quincke He assisted in the investigations leading to improvements in the production of zinc by the electrolysis of zinc chloride and to the discovery of nickel carbonyl, the basis of the process for the production of pure nickel In the course of time, Robert Mond was called upon to assume positions of responsibility in various organizations arising from the exploitation of scientific investigations at Winnington He joined the board of directors of Brunner Mond and Company and the Mond Nickel Company, of which he subsequently became chairman

In connexion with the exploitation of the nickel mines at Sudbury Ontario, Robert Mond identified himself with the Royal Ontario Museum, Toronto, of which he became trustee and to which he gave considerable sums of money and also enriched by valuable contributions arising from his archæological investigations in Egypt His absorbing interest in archæology dates from about 1898, when, shortly after his marriage, he had to spend winters out of England for health reasons In his earlier days, Robert Mond was a keen mountaineer, and later, although never of sound physique, his unusual vitality made it possible for him to undergo physical strain which always surprised those who knew him intimately

In 1910 Robert Mond went to live at Combe Bank, Sevenoaks—one of the first houses to have electric lighting installed—with its model farm and laboratories originally intended for his father s use Characteristically and with his usual vigour, Robert Mond took up for him new investigations in agriculture, including stock breeding and it was from here that he supplied with milk the Infants Hospital in Vincent Square founded as a memorial to his late wife The late Prof H E Armstrong used to maintain that Robert Mond was the first to appreciate the meaning of pure milk and to conduct his experiments on a satisfactory scale

It is difficult to give an adequate account of Robert Mond s scientific and industrial interests His scientific greatness lay not so much in what he himself discovered or achieved but in what he did to make it possible for those to achieve who were less fortunately placed Especially after his father s death, he regarded his wealth and position as a trust to be used in the advancement of knowledge and appreciation of beauty, and through that of international peace and fellowship, and he worked incessantly to achieve this ideal

The large number and extent of Robert Mond s benefactions will probably never be known to the outside world and if by chance he happened to mention any one of them to an intimate friend one felt that he had been guided by his ideals rather than by the mere amelioration of a difficult financial situation Some of them in Great Britain are known There is his large benefaction to the University of Liverpool, of which he held the honorary LL D degree Another typical example of what he has done for the advancement of scientific knowledge is his work for the Royal Institution Sir Robert Robertson, the honorary treasurer, has written

> "By the same deed of trust (1896) of Ludwig Mond in which he conveyed the Davy Faraday Research Laboratory and its endowment to the Royal Institution, Robert Ludwig Mond was named Honorary Secretary of the Laboratory Committee for life When in London he came occasionally to the meetings of the Committee and read the minutes To the equipment and furnishing of the Davy Faraday Laboratory, he gave much thought and travelled over the Continent and in America studying arrange-

ments of laboratories and purchasing apparatus for his father's foundation. Although forty years have passed since the laboratory was fitted up according to his designs, the arrangements of benches and of electrical distribution are still in use. At the celebration of the centenary of Faraday's discovery of electricity from moving magnetism (1931), he represented the Faraday Society and gave £5 000 towards the reconstruction of the theatre. His interest in the Davy Faraday Laboratory continued unabated and recently he gave £2 000 to its funds. He also caused to be collected and printed a list of workers in the laboratory from 1896 to 1932 with their publications. The Royal Institution has lost a good friend.

It is interesting to note that Robert Mond's knowledge of the Royal Institution and the unique place it occupies as a scientific centre guided him to a large extent in what he did later in Paris. Much more recently, he gave a sum corresponding to the amount he gave to the *Maison de la Chimie* in Paris to the funds of the National Council for Chemistry. Like his father, keenly interested in the documentation of scientific knowledge, he hoped that this might be a nucleus from which the more satisfactory documentation of chemical literature and, possibly, a British House for Chemistry might arise.

In celestial chemistry and other related branches of astronomical research, Robert Mond also took keen interest and encouraged in many ways. He was one of the seven original subscribers to the Hill Observatory Corporation, registered in 1916 to establish an observatory at Salcombe Regis, Sidmouth, Devon, the name being changed in 1921 to the Norman Lockyer Observatory, in memory of the distinguished astronomer who founded it. He became chairman of the corporation twenty one years ago and occupied that position when he died. Since its foundation, the Observatory has been equipped and maintained entirely by private donations, and Robert Mond was one of its chief benefactors. Six years ago, he generously presented to the Observatory a completely new form of photographic equatorial telescope, which he termed an 'astronomical robot' for the photography of extensive celestial fields with long exposures and on different scales.

In recent years, Robert Mond became as much at home in France as in Great Britain. This was partly a result of his ardent desire to improve international understanding among scientists generally and chemists in particular. In France, he was a generous benefactor of the British Institute in Paris, and he worked wholeheartedly for the France Grande Bretagne Association. Our French colleagues realized his unique qualities and honoured him (and us) by electing him president of the Société de Chimie industrielle, an office which he held at the time of his death.

The founding in Paris of the Maison de la Chimie as a memorial to Marcelin Berthelot appealed to Robert Mond intensely. In his own words, "L'idéal que matérialisent ces bâtiments a permis de créer mieux qu'une maison : un état d'esprit international. Et c'est cette foi commune qui, loin des luttes de la politique, cherche à élever toujours plus haut les manifestations de l'intelligence scientifique et le rayonnement du génie humain." He became Membre du Conseil d'Administration de la Maison de la Chimie and, apart from contributing 1,000 000 francs to its funds and in order that its future and development might be secured he founded and became president of the Société des Amis de la Maison de la Chimie. What he did for the Maison de la Chimie was typical of many other benefactions in France all carried out in the spirit of furthering the accomplishment of his ideals. France fully recognized the high quality of his efforts, and none of his friends were surprised at his promotion from Officier' to Commandeur de la Légion d'Honneur. In 1937, he was elected Membre de l'Académie des Inscriptions et des Lettres, becoming Membre de l'Institut de France.

Robert Mond received the order of knighthood in 1932. Of his election this year to the fellowship of the Royal Society he was immensely proud. His letter to the present writer contained the following sentence: "To be considered worthy of admission to the same distinguished Society which recognised my father is the greatest honour I could receive." Arrangements had been completed for conferring on him, by the University of London, the rare distinction of the honorary D.Sc. degree.

Robert Mond's interests in human knowledge and progress were so wide that it is difficult to realize how he found time and strength to maintain them. Recently he suffered considerable physical disability, but his amazing spirit and the constant care of Lady Mond carried him through. In spite of ill health, he never hesitated to accept an office to which arduous duties were attached when he believed that thereby he might contribute to the realization of his ideals. The international character of the meetings of the Faraday Society was a deciding factor in accepting its presidency, and his interest in photography and especially in colour photography from his early days led him to accept the honorary treasurership of the building appeal (now in progress) of the Royal Photographic Society.

Robert Mond died at his Paris residence on October 22. All who knew him and enjoyed his friendship will warmly endorse the sentiments so ably expressed at the funeral by Prof. Auguste Béhal and Louis Hauzeur. The ashes are interred at Belle Isle en Terre. To Lady Mond and to the family we can only express our deepest sympathy and feel proud that we have been privileged to know a great man who described himself as "un serviteur modeste mais dévoué de la Science".

CHARLES S. GIBSON

IN the passing of Sir Robert Mond, Egyptology has lost one of its most generous supporters, as well as a most devoted student. Ever ready to help in financing explorations in the field, he himself took the keenest pleasure in the actual work of excavating and enjoyed nothing better than being at the bottom of a tomb shaft, sifting the sand with his own hands in the hope of finding some hidden treasure.

It was my privilege to meet Mond first at his father's house in London in 1896, and when he visited Egypt a few years later he came to me at Thebes and expressed the wish to collaborate in the exploration of the Mortuary Chapels of the Nobles which I was then carrying out on a very small scale in the Theban necropolis In 1902 when I relinquished this work in consequence of other duties Mond took over the concession which I then held from the Egyptian Government and early in 1903 began working the concession himself This work he continued for the next three winters and published his reports in the *Annales du Service des Antiquités* then being edited by Prof Maspero Later when he was prevented from personally supervising the excavations Messrs Howard Carter and Arthur Weigall the successive inspectors of antiquities in Upper Egypt continued the task with the financial aid of Mond and others In 1909 he sent out from England Mr Jelf an Oxford graduate to assist Weigall In 1913 was published the Topographical Catalogue of the Theban Tombs by Dr Alan Gardiner and Weigall with the assistance of Mond which is a record of what had up to then been accomplished In the introduction to this book, Gardiner wrote that it was due in large part to the personal endeavours and enlightened liberality of Mr Robert Mond that the Theban Necropolis is now on the whole well protected and in a satisfactory condition

Mond now set himself whole heartedly to work out a well considered and continuous scheme of restoration and preservation of the Theban tombs In a lecture which he delivered before the Royal Institution in May 1914 he told his audience that this object which had been one of my day dreams for many years took shape when the opportunity arose which enabled me to secure after many consultations with the most competent Egyptologists and especially with Dr Alan Gardiner the services of Mr Ernest Mackay for many years the chief assistant of Prof Flinders Petrie and he announced that Mackay will now devote his whole time to the systematic inspection excavation restoration and preservation of these chapels But Mackay had been employed only a little more than a year when the Great War broke out and soon afterwards the work at Thebes had to be abandoned

It was not until the winter of 1923 that Mond again began explorations at Thebes when he employed Mr Yeivin in the autumn of that year to superintend the excavations The same year Mr Walter Emery a student of the late Prof Peet at the University of Liverpool, was sent out to Egypt and in 1924 took charge of the work Mond's work was now carried out in association with and under the ægis of the University of Liverpool Institute of Archæology an institution that he had long been interested in having joined the Committee in 1910 On going over the necropolis with Emery it was decided to clear and restore the famous tomb of Ramose, vizier of Amenhetep III and Akhenaton This took three winters to complete, and the publication of the scenes and inscriptions in it has been entrusted to the skilled hands of Mr Norman de Garis Davies, of Oxford, and for many years on the staff of the Metropolitan Museum of Art, New York Mond's and Emery's reports for the years 1923 to 1926 are printed in the *Liverpool Annals of Archaeology and Anthropology*

In the spring of 1926 Mond and Emery prospected on a new site at Armant the ancient Hermonthis ten miles up river from Thebes A concession covering about fifty square miles was applied for in the name of the Liverpool Institute of Archæology and when this was granted Mond began excavating there The burial ground of the Buchis Bulls sacred animals famous in Egyptian history was soon discovered Mond then had a motor road some ten miles long cleared from Thebes to Armant to enable him to visit Emery two or three times a week to inspect the work and record progress In 1928 the Armant concession was transferred to the Egypt Exploration Society of which Mond had been elected president on the death of General Sir John Maxwell A large staff was sent out under the direction of Dr Frankfort Mond bearing the whole expense In the following year Frankfort resigned on being appointed field director of the Iraq Expedition of the Oriental Institute of the University of Chicago and the Armant excavations were supervised for a season by Mr F W Green, of the Fitzwilliam Museum Cambridge Emery having been appointed by the Egyptian Government to carry out the Nubian Archæological Survey Then Mr Oliver Myers was appointed director a position he has held ever since

How ably this work has been carried out is evidenced by the three volumes published in 1934 entitled The Bucheum by Sir Robert Mond and Oliver Myers and by two volumes issued last year on The Cemeteries of Armant by the same authors To these books no fewer than sixty nine scholars and scientific workers have contributed among them many bearing distinguished names It is interesting to note that two Egyptians have written chapters one G Mattha a student of the late Prof Griffith writes on Demotic Ostraca the other Suliman Huzayyin contributes an able paper on The Flint Industry These volumes show how wide was Mond's outlook in Egyptology and how catholic were his interests Although much more remains to be published of the work he was engaged on it is pleasant to know that he lived to see these five volumes distributed During the last two years Mond also financed the work of Dr Hans Winkler in the Eastern and Libyan deserts, a small volume Völker und Völkerbewegungen im vorgeschichtlichen Oberägypten im Lichte neuer Felsbilderfunde was issued last year and Rock drawings of Southern Upper Egypt by the same writer has just appeared

Before concluding this notice of Sir Robert Mond's Egyptological activities as an example of his keenness in the preservation and provision for the careful publication of antiquities may be mentioned his acquisition of a unique series of papyri When we were at Thebes in the spring of 1904, we heard that native diggers had made a 'find of Hebrew papyri at Elephantine Mond at once telegraphed to the dealer who had secured the documents, asking that they should be kept for his inspection Next morning, he set off for Aswân and at once bought the papyri with the intention of presenting them to the British

Museum But the Service des Antiquités, hearing of the purchase, requested Mond to sell the documents to the Cairo Museum Recognizing that this was really a command, he at once presented the collection to the Cairo Museum authorities on condition that he should have the right of publication He then commissioned Prof Sayce and Dr Cowley, of Oxford, to edit and translate the documents, and in 1906 was published the splendid volume Aramaic Papyri discovered at Assuan This was due entirely to Mond's munificence Mond possessed a collection of antiquities at his home in Cavendish Square but it was his invariable habit to give the best pieces he bought to museums rather than keep them himself He was the first to contribute on a munificent scale toward the purchase of the important Petrie Collection of Egyptian Antiquities for the University of London, and the Toronto Museum has benefited greatly by his gifts

PERCY E NEWBERRY

WE regret to announce the following deaths

Mr H G Billson C I E, formerly chief conservator of Indian forests on October 27

Paul Helbronner free member of the Paris Academy of Sciences who made a geodesic survey of the French Alps from Lake Geneva to the Mediterranean and later extended the network to Corsica on October 18, aged sixty seven years

Dr Volkmar Kohlschutter professor of inorganic and physical chemistry in the University of Bern on September 10 aged sixty five years

Prof P A Murphy, professor of plant pathology in the Albert Agricultural College University College Dublin on September 27 aged fifty one years

Prof Georges Urbain professor of chemistry in the Sorbonne on November 6 aged sixty six years

Miss Clotilde von Wyss formerly lecturer in natural history in the Institute of Education (University of London) on November 7

News and Views

Royal Society Awards

THE following awards of medals have been made by the president and council of the Royal Society Copley Medal to Prof Niels Bohr For Mem R S in recognition of his distinguished work in theoretical physics and particularly in the development of the quantum theory of atomic structure, Rumford Medal to Prof R W Wood, For Mem R S, in recognition of his distinguished work and discoveries in many branches of physical optics Davy Medal to Prof G Barger, F R S, in recognition of his distinguished researches on alkaloids and other natural products, Darwin Medal to Prof F O Bower, F R S, in recognition of his work of acknowledged distinction in the field in which Darwin himself laboured, Hughes Medal awarded jointly to Dr J D Cockcroft, F R S, and Dr E T S Walton, in recognition of their discovery that nuclei could be disintegrated by artificially produced bombarding particles

Lord Lugard, G C M G

A BRONZE statuette of Lord Lugard has been presented to the Imperial Institute by members of the Royal African Society as an addition to the collection of statuettes of empire builders in the Institute's galleries The presentation took place on November 7, when the statuette, which stands in the Nigerian Court, was unveiled by the Earl of Athlone, president of the Society, and formally accepted by Sir Harry Lindsay, director of the Institute The statuette which is half life size, is the work of Mr Herbert H Cawood, who has executed the effigies of Cabot, Van Riebeck, Raffles, and Livingstone in the collection Lord Lugard is the only living subject represented The presentation marks the fiftieth year since Lord Lugard's first service in Africa His brilliant success as an administrator of native affairs has been due to his application of the policy now known as indirect rule to tribal government in order to secure maintenance of law and order through the least disturbance of tradition by the imposition of civilized authority His book The Dual Mandate in British Tropical Africa (1922) not only gained him the award of the Gold Medal of the Royal Geographical Society, but immediately became a classic as Lord Athlone said in his address of presentation when he also spoke of Lord Lugard as the father of indirect rule Owing to his advocacy and the practical demonstration of its efficiency in Nigeria the principle of indirect rule with or without modification, has been extended to the other British colonial possessions in Africa In 1922-36 Lord Lugard was the British representative on the Permanent Mandate Commission of the League of Nations while as Chairman of the Council of the International Institute of African Languages and Cultures, he has inspired and guided a great work of scientific research on the peoples and languages of Africa

Miss Lise Meitner

MANY readers of NATURE will wish to join with her friends in offering their congratulations to Miss Lise Meitner on the occasion of her sixtieth birthday, which she celebrated in Stockholm on November 7 It is now more than thirty years since Miss Meitner left Vienna for Berlin to begin work on radioactivity with Prof Hahn, and throughout the whole of that period, both alone and in collaboration she has contributed as much almost as any one person to the subject to which she devoted all her energies During the years 1908–10, in collaboration with Hahn, she studied in detail the radiations from the active deposits of radium, thorium and actinium, obtaining the first indications of the existence of the C″ bodies and of the radiations from radium D. Between 1911 and 1915, with v. Baeyer and Hahn she studied the groups of β particles by the direct deviation method showing that α ray as well as β ray bodies give rise to such groups. After the Great War, Miss Meitner turned to the semicircular focusing method for the further study of the β ray groups, regarding them now as secondary radiations associated with γ ray emission, and was the first to maintain that in the process of disintegration the emission of radiation follows, rather than precedes the emission of the particle. Experiments on the long range α particles with Freitag on the heating effect of the β particles of radium E with Orthmann and on the scattering of hard γ rays in collaboration with Hupfeld, occupied the years 1926–32. Since 1932 Miss Meitner has devoted her attention more and more to studies of nuclear transmutation and artificial radioactivity. With Hahn and Strassmann she has investigated particularly the complicated series of bodies obtained by bombarding uranium and thorium with neutrons.

R.A.F. Long-distance Non-stop Record Flight

THREE R.A.F. Vickers Wellesley bombers, two of which landed at Darwin, Northern Australia, at 4 a.m. (G.M.T.) on November 7, have broken the world's long-distance record held by the Russian airmen who flew from Moscow to San Jacinto (California) a distance of 6,306 miles. The two Vickers machines covered a distance of 7,162 miles non stop, from Ismailia to Darwin while the third was forced to land at Koepang, Timor, 400 miles short of this, owing to lack of fuel. It afterwards completed the journey, arriving at Darwin at 7.36 a.m. Their speed averaged about 149 miles per hour, as compared with 102 miles per hour for the Russian record. The actual machines and their crews are a flight known as the Long Range Development Unit of the R.A.F., under the command of Wing Commander Gayford, specially charged with the duties of investigating service problems associated with long distance flying. Early in the flight, they flew in formation under the command of Squadron-Leader Kellett, but later they separated, the other two machines under Flight Lieutenants Hogan and Combe each flying independently.

THE aircraft are standard Vickers Wellesleys as supplied as bombers to R.A.F. squadrons, modified for very long distance flights, principally having greater fuel tank capacity. They are cantilever monoplanes built with Vickers geodetic method of construction. The exceptional lightness of this structure allows a correspondingly large weight of fuel to be carried within the limitation of their maximum weight. They are fitted with retractable undercarriages, totally enclosed cabins and all other devices for reducing their drag to a minimum, thus keeping the power required as small as possible. The Bristol Pegasus XXII engine with its very low fuel consumption, adding to these refinements, has given the combination that makes a flight of this length possible. The machines were fitted with automatic pilots, which relieve the pilots of much of the necessity for actually holding the controls on a long fixed course. Sleeping accommodation was arranged in the cabins, and the other two members of each crew, navigator and wireless operator, were qualified pilots, able to control the aircraft when required.

Planning for Defence

A BROADSHEET issued by PEP (Political and Economic Planning) entitled "Planning for Defence" directs attention to the necessity for fundamental thinking as to the values upon which the society that is being planned is to be based. The dangers of running a world by standards which are largely distorted for immediate material ends is clearly revealed by the events of September last, and realization of those dangers may well compel a reassessment of values, checking the drift towards opportunist materialism, and the evolution of a more explicit code of values on which the democracies and people in all countries who are not prepared to succumb to temporary illusions can take their stand as a basis for working towards a more tolerable human society. Simultaneously, specific thinking about the problems of a society and economy functioning under the shadow of war is urgently demanded and reinforces the case for eliminating waste in distributive services and elsewhere, the conservation of national resources, the adoption of economic operating units for public services and the rationalization or decentralization of some of the local government services or functions and staffs concentrated in London.

THE broadsheet suggests that such adjustment must be based on three principles: maximum efficiency (which in wartime might not coincide with efficiency in peace), the maintenance or even extension of ultimate democratic control, particularly in the economic sphere whatever special powers might be needed, and the framing of emergency measures so far as possible in accord with the long term needs of social and economic reconstruction. The importance of local self reliance is stressed, for an educated democracy requires both resolute leadership and information on which to base its judgment and actions. It will be necessary to think out very carefully the respective functions of the local committee or council, of the executive officers who perform the local service and of the officer who represents the requirements of the central government. While the central government would require decentralization, many local services require larger operating areas for efficiency. The broadsheet further refers to the need for public information, for rationalizing transport and distribution, for keeping a balance between demands and the normal economic life of the community. The structure of industry and especially the location of new plant present special problems, and, in regard to man power, one of the most serious problems is that of utilizing professional and technical workers. Nutrition policy and food control, land policy, the acquisition of development rights are other questions to which the broadsheet briefly directs attention.

Protection against Propaganda

Science Service of Washington, D.C., has published under the title "Propaganda Protection" a series of short articles forming an exposition of the methods and aims of war propaganda. The chemist and physicist are frequently criticized for discovering poison gases and high explosives, but without the will of the fighter the destructive compounds would be powerless. The aim of the propagandist is to make people willing to act in a particular way, and his general means are the arousal of emotion and the stifling of reason. The specific methods are the appeal to prejudice and hate by the use of slogans, by the demand for haste since delay may bring reason into play, by the use of statements that can neither be proved nor disproved, by concealing the source of the statements, and by persuading the hearer or reader to associate particular evils, for example, conspiracy, plotting, oppression, injustice, and particular virtues, for example, bravery, sympathy, humanity, patriotism, with some particular creed, party, or country. The propagandist knows the weaknesses of mankind and in many cases consciously exploits them for his own ends. The general methods are not new in the history of mankind, but the development of the means of communication by travel and radio has made all of us much more vulnerable to the propagandist attack. It is commonly asserted that more knowledge is the best immunizing agent against propaganda; but to be effective we need much more knowledge of our own mental make-up, as well as greater knowledge of facts outside ourselves. It is unfortunate that our knowledge of psychology lags so far behind our knowledge of other aspects of reality.

Physical and Mental Welfare Society of New Zealand

On July 22 last, a body known as the Physical and Mental Welfare Society of New Zealand was formally incorporated; the object of the Society is, broadly, to promote the application of current scientific knowledge to physical and mental welfare. The Society originated in a movement which has existed and operated throughout the Dominion for several years. It was promoted by a group of voluntary workers in the social services, under the leadership of Mrs. Ysabel Daldy, who has hitherto worked under the *noms de plume* of "Mother Machree" and "Silent Peter". In numerous weekly articles contributed to some twenty New Zealand newspapers, she has interpreted current scientific knowledge in its bearings on social welfare to the general reader in simple and attractive language, thus moulding public opinion and preparing the way for necessary reforms. She has been assisted by the "Silent Peter" group of specialist advisers, which is stated to include representatives of the medical profession and others well qualified severally to advise and write on health, nutrition, agriculture, education and some branches of science. Through her articles in newspapers and by correspondence with Government departments and with individuals, Mrs. Daldy has done valuable work in guiding and stimulating public opinion, and the increased opportunities afforded by the new Society of reaching the public by lectures, publications and other means, should enable this body of scientific opinion to exert its full influence in promoting the application of science to social problems in New Zealand.

Archæological Investigations in the Hadramaut

Further details of archæological investigations in the Hadramaut of southern Arabia were given by Miss G. Caton-Thompson in a lecture before the Royal Geographical Society on November 7, in which she described the results of the expedition undertaken by Miss Elinor W. Gardner, Miss Freya Stark and herself in the winter of 1937–38. The uniform, but crude character of the palæolithic industry of the region, to which she referred in her preliminary report (see Nature, 142, 139; July 23, 1938) was again emphasized. This industry falls well within the limits of the Levallois flake industry; but its crudity is strikingly apparent on comparison with the corresponding industries of Africa, North Arabia and Palestine. It represents a low ebb in contemporary standards, which Miss Caton-Thompson is inclined to attribute either to the influence of a harsh and impoverished environment, or possibly to the absence of technical stimulus from contact with more progressive groups such as, for example, might have been supplied from East Africa. The latter alternative postulates the separation at an early date in the Pleistocene or before of south-west Arabia from East Africa. The conception of an early marine separation of the two regions is reinforced by the fact that of the three culture groups classified morphologically by the hand-axe, the flake, and the blade industries, the hand-axe culture group, which covers practically the whole of Africa, failed, so far as the evidence goes, to reach south-west Arabia. The huge numbers of flint implements of Levallois type argues a *status quo* so far back as the middle or later Pleistocene. Of the evidence of plant life found in the tufa in the Wadi Luqrun, absence of structure makes identification impossible; but one is a species of *Celtis*, another type, the commonest, resembles the fig in leaf; and some kind of palm is certainly present.

The Government Laboratory

Seventeen thousand samples in excess of the number submitted in the previous year are recorded in the report of the Government Chemist as having been examined in the year ended March 31, 1938. The total number was substantially larger than half a million. The work of the Laboratory, however, is not to be measured by numbers alone, for it involves much research into the reliability of existing methods of analysis, and many investigations into new methods of detection and determination of substances. Further, the staff is constantly being consulted on technical matters, while, in addition, its members contribute notably to the advance of pure and applied chemistry both by publication and by personal service on numerous committees. In its analysis of the results of the examination of 848 samples of imported butter, the report shows that the water content of considerably more than half of the samples was between 15 and 16 per cent, the Reichert value of the fat varied from 24·0 to 34·0 (in 555 cases from 28 to 32), while the Polenské value varied from 1·0 to 3·35. Of 87 samples of tinned cream, 81 contained between 20 and 29 per cent of fat; of 127 samples of cheese, 17 per cent had been prepared from milk containing less than one half of its fat. In neither case is it at present possible to take exception to such importations. The examination of water included sea water studies for the use of hydrographers and biologists, on rivers in connexion with fish and fish food, and on water-cress beds in relation to the use of the national mark. Of 2,270 samples of brewing materials, 18 contained arsenic in slight excess of the accepted limit. It is satisfactory to learn that owing to the stringency of the tobacco laws and the high standard of the tobacco industry in Great Britain, adulteration is almost non-existent. The Laboratory has also been concerned with such widely different matters as the pollution of foreshores, the manipulation of radioactive materials, the carriage of dangerous cargo, and the work of the Bed-bug Infestation Committee.

Carrier Telephony

An instructive address on carrier telephony was delivered to the London Students' Section of the Institution of Electrical Engineers, on October 31 by its chairman, P. H. Pettifor. The frequencies present in the normal speech range are included between the limits 75–9000 cycles per sec., but for intelligible and 'natural' speech, it is only necessary for the listener to hear a very small portion of that spectrum, and in normal telephone practice the range lying between 300 to 2700 cycles per second only is used. This possible restriction in the range necessary for satisfactory speech is fully utilized in carrier telephony. The lower the frequency of the transmitted band the greater the number of channels which can be accommodated for that band. A carrier-current telephone system is one in which the normal voice frequencies are raised to a band of higher frequencies before being transmitted over the open-wire line or cable, conversion to the normal voice frequency band taking place at the receiving station. If different circuits have their voice frequencies raised by amounts such that the high-frequency bands do not overlap one another, then one cable pair can be used to transmit speech to several circuits, without the circuits interfering with one another. In this way the signals in several circuits can be transmitted over one cable pair without any interference taking place. The development of the principles of carrier telephony has been slow; the early experiments were made by Ruhmer in 1909, before the present-day thermionic devices were developed. A brief description was given of the post-War development in this field, including the latest cable design technique. Amongst the types of cable described was a cable containing a pair of air-spaced self-locating conductors. This type of cable is laid around London for television purposes. Another type containing four coaxial conductors has been laid between London and Birmingham. A similar coaxial cable containing only one coaxial conductor insulated with para-gutta has also been found very useful. With modern systems the level of cross talk between channels is practically negligible when compared with the normal voice frequency systems.

A 'New Deal' in Education

President Roosevelt's Advisory Committee on Education, appointed in September 1936, has presented a report (Government Printing Office, Washington, 1938. Pp. 244. 35 cents) on the whole subject of Federal relationship to State and local conduct of education. After a comprehensive study of the entire field of educational service, the committee found that there is great need for improvement of the public schools in a number of broad geographical regions and in the rural areas generally. To redress the existing gross inequalities of educational opportunity it submits a set of carefully articulated proposals forming, as is justly claimed, "a unified and coherent pattern of Federal policy" and involving a six years plan for Federal grants for educational services amounting in the aggregate to 1,200 million dollars. Most of the new grants recommended fall under the headings: general aid to elementary and secondary education, preparation of teachers and other educational personnel, school buildings, administration of State departments of education, educational services for adults, library service for rural areas. A system of co-operative research accompanied by demonstration projects throughout the country has proved its value in the field of agriculture, and the committee recommends the establishment of a special Federal fund for the immediate application of such a system in the field of education. In the first instance it would be utilized especially for elucidating in advance problems bound to arise in connexion with the operation of the six years plan for Federal grants.

The Colombo Museum

The administration report for 1937 of the acting director of the Colombo Museum, P. E. P. Deraniyagala, shows that in many directions the activity of the museum is maintained. Steady additions are being made to the zoological collections, notably by expeditions carried out by the staff or by the staff jointly with representatives of the British Museum, so that the director considers that the accumulation of material is now sufficient to justify the publication of detailed monographs. At the same time, attention ought to be directed to the public galleries, and the replacement of the misleading and faded specimens in the bird gallery would doubtless be appreciated by the half-million visitors who pass through the galleries each year and especially by the large number of school-children (12,288) who make use of the exhibits in the course of their nature study instruction.

A suggestion that the collection of living animals should be transferred to the Government Zoological Gardens at Dehiwala was strenuously opposed by the Committee of Management, and instead efforts are being made to improve and extend this museum zoo, which is an invaluable educational adjunct to the mounted collections. The Ethnological Department has begun a survey of the native population, and various expeditions have been carried out for a study of cultural institutions and social and economic conditions.

Trachoma in Tunisia

In a recent study (*Thèse de Paris*, 1938, No. 142), Dr. C. Koskas states that trachoma was probably imported into Tunisia by immigrants from North Africa, Italy, Malta and Spain. Although it is a notifiable disease, the natives, who do not recognize the gravity of the condition, evade the law, and comparatively few cases are actually notified. The only means of determining in any way the frequency of the disease is by medical examination of school children or of recruits for the army. There is no doubt, however, that infection rarely occurs in adults or in the schools; but that it is usually contracted in the early months of life. The incidence of the disease is much higher in the south where the climate is hot, the sirocco violent and frequent, the atmosphere laden with dust and sand, and the inhabitants poverty stricken and underfed than in the north of Tunisia. Flies play an important part in the transmission of the disease, as was shown by Nicolle and Cuenod in 1921, Petit in 1925 and Mme Delanoe in 1930; but race does not influence the incidence or gravity of the disease. Good work has been done by the establishment of ophthalmic departments where free advice and treatment are given.

Electrical and Allied Manufacturers' Association

The eleventh edition of a pamphlet giving information about the British Electrical and Allied Manufacturers' Association (BEAMA) has just been published. The president of the Association is the Earl of Derby. The objects of the Association are to foster and protect the electrical and allied industries in Great Britain. It aims at securing the co-operation of every firm in the electrical and allied industries so that, by co-operative action, it can speak for the whole of those industries on all matters affecting them. The Standardization Committee acts as a centre and clearing house for the many activities of its members in connexion with standardization and the British Standards Institution. The Association's numerous technical and other committees are continuously at work in the interests of the sections by which they are appointed and of the members generally. The address of the Association is 36 Kingsway, W.C.2.

Earthquake in Bulgaria on November 6

At approximately 21 h. G.C.T., an earthquake damaged property and felled chimneys in the Gabrovo district in north Bulgaria. Many people were alarmed, but no loss of life is reported. Bulgaria as a whole must be considered an earthquake country, though the north has not been subjected to so many as the south. The chief epicentral region in north Bulgaria is around Tirnovo, and the next in importance is the Déli-Orman. Further information concerning the shock will probably come shortly from Dr. K. T. Kiroff and his colleagues at the observatory at Sofia.

Japanese Earthquake of November 5

An earthquake was experienced in the Miyagi Prefecture in the north-east of the main island of Japan at 8 h. 44 m. G.C.T. (5.44 p.m. local time), and an after-shock followed two hours later. The focus appears to have been at some considerable depth, as the shock was felt in the four Prefectures of Miyagi, Iwate, Fukushima and Ibaragi, and even as far as Tokyo, though no damage is reported from this city. In this part of Japan there is a well-defined belt of earthquake epicentres stretching from Kamagata through Wakamatsu and Utsunomiya to Choshi. Severe earthquakes happened in the north end of this belt in 1893, 1894 and 1895, the last two from the same epicentre, though more recently strong earthquakes have been more frequent along parallel belts to the south, west, north, and seaward of this. The shock which was recorded on seismographs at Kew and elsewhere in Great Britain at 8 h. 55 m. 59 s. G.C.T. and mentioned in the general press in connexion with the above, was not due to the Japanese earthquake but was from some epicentre at about 87 from Kew, though the exact location is not yet determined.

Commonwealth Fund Fellowships

The total number of Commonwealth Fund Fellowships offered for award in 1939 is thirty four. These fellowships are tenable at certain American universities. Candidates for Ordinary Fellowships must be of British descent who are domiciled in the United Kingdom of Great Britain and Northern Ireland, and are degree graduates of recognized universities therein. Candidates for Dominion Fellowships must be of British descent from the British Dominions, who have studied, but not necessarily graduated, at a university in the United Kingdom of Great Britain and Northern Ireland, who are degree graduates of a recognized university in a British Dominion or Colony. Candidates for Service Fellowships must be of British descent and must hold appointments overseas under the British Government, or the Government of India, or the Government of a British Dominion, Colony, Protectorate or Mandated Territory; and those for Home Civil Service Fellowships must be holding appointments in the Home Civil Service. None of these fellowships is open to women. Further information can be obtained from the Secretary to the Committee, Commonwealth Fund Fellowships, 35 Portman Square, London, W.1.

International Union of Geodesy and Geophysics

The International Union of Geodesy and Geophysics will hold its seventh general assembly in Washington, U.S.A., on September 4–15, 1939.

Invitations have been extended on behalf of the President of the United States to the participating countries to be represented by delegates on this occasion The American Geophysical Union is the American section of the International Union of Geodesy and Geophysics, and its executive committee is the Committee on Geophysics of the National Research Council The Council is collaborating with the American Geophysical Union as host to the assembly The last general assembly of the International Union was held at Edinburgh, Scotland, in September 1936 The thirty five nations at present adhering to the International Union are Argentina, Belgium, Brazil, Bulgaria, Canada, Colombia, Chile, Czechoslovakia, Denmark, Egypt, Finland, France, Germany, Great Britain, Greece, Holland, Hungary, Indo China, Italy, Japan, Morocco, Mexico, New Zealand Norway, Peru, Poland, Portugal, Rumania, Siam, Spain, Sweden, Switzerland, Union of Soviet Socialist Republics, United States, and Yugoslavia

Another Large Sunspot

The giant sunspot which crossed the sun s disk between October 5 and 18 broke up before its return due at the eastern limb on November 2 Meanwhile, another large spot had formed in solar longitude 273° and in latitude 9° south This spot came round the limb on November 4, though it was not completely seen until the following day, when its area was 2000 millionths of the sun s hemisphere The time of central meridian passage was November 10 8 U T , its date of disappearance around the western limb will be November 17

Announcements

Dr W D Lang, keeper of the Department of Geology of the British Museum (Natural History), is to retire on December 29 The principal trustees of the Museum have appointed Mr W N Edwards, deputy keeper of the Department, to succeed Dr Lang Mr Edwards was born in 1890 and was a scholar of Christ s College, Cambridge He entered the British Museum (Natural History) as an assistant in the Department of Geology in 1913 and became deputy keeper in 1931 He is an authority on fossil plants and has travelled extensively

Dr T S Wheeler, principal of the Royal Institute of Science, Bombay, has left India and will shortly take up his new appointment as State Chemist, Eire

Mr J Wickham Murray, secretary of the Association of Teachers in Technical Institutions, has been appointed an official for higher education by the executive of the National Union of Teachers

At the anniversary meeting of the Mineralogical Society on November 3, the following were elected officers *President* and *Editor of the Journal*, Dr L. J Spencer, *Vice Presidents*, Prof C E Tilley and Lieut -Colonel W Campbell Smith, *Treasurer*, F N Ashcroft, *General Secretary*, G F Claringbull, *Foreign Secretary*, Sir Thomas Holland

A symposium on ' Gas Temperature Measurement" will be held by the Institute of Fuel in the lecture theatre of the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W C 2, on December 2 It will commence at 10 30 Further information can be obtained from the Secretary, Institute of Fuel, 53 Victoria Street, London, S W 1

The Royal Sanitary Institute Congress of 1939 will be held at Scarborough on July 3–8 and the Congress of 1940 at Torquay on July 1–6 Further information can be obtained from the Secretary of the Institute, 90 Buckingham Palace Road, London, S W 1

A fourth Farming Conference will be held at Oxford under the joint auspices of the School of Rural Economy, the Agricultural Economics Research Institute and the Institute for Research in Agricultural Engineering of the University of Oxford on January 3–5 1939 Further information can be obtained from the Conference Secretary, 10 Parks Road Oxford

The Far Eastern Association of Tropical Medicine will hold its tenth Congress at Hanoi, Tonkin, on November 24–30, when discussions will be held on feeding in deficiency diseases, cholera malaria, plague, tuberculosis, venereal disease surgery, diseases common to man and animals parasitology and local anthropological characteristics

The next International Congress of Surgery will be held in 1941 at Stockholm under the presidency of Dr Leopold Mayer

The Congress of Comparative Pathology will be held in Rome on May 15–20 1939 under the presidency of Prof Rondoni, director of the Cancer Institute at the University of Milan The following subjects will be discussed ultra virus diseases, heredity in pathology, the association of antigens and their function, regressive processes in plants The secretary of the Congress is Prof Zavagli at Consiglio Nazionale delle Ricerche, Piazzale delle Scienze, Rome, from whom further information can be obtained

The Home Secretary proposes to make regulations under the Factory Act 1937 extending the provisions of Section 66 to compressed air illness Copies of the draft regulations may be ordered through any bookseller from H M Stationery Office

The Pasteur Institute of Algiers, of which Dr Edmond Sergent is director, has been authorized by the French Government to sell a serum against scorpions prepared from immunized horses

Erratum In Nature, November 5, p 843 "Origin of the Solar System", last line of first paragraph, for "internal" read "external".

Letters to the Editor

Formation of a New Phosphate Ester in Kidney Extracts

THE phosphorylation of sugars and glycerol in kidney extracts is increased by addition of fumaric or malic acid and this effect is caused by a stimulation of the tissue respiration[1]

If fumaric or malic acid is added to extracts from washed kidney pulp the phosphorylation, which is very slight in preparations without substrate is increased considerably and the respiratory rate is also accelerated Since these extracts are very poor in phosphate acceptors, it is most likely that fumarate and malate are converted through oxidation to a phosphate acceptor A more detailed investigation definitely established the formation of a new phosphoric ester quite different from the hexosediphosphate formed from glucose and fructose[2] The characteristics of the phosphoric ester formed from the oxidation products of malate agree completely with those of phosphopyruvic acid[3]

Kidney cortex from a fasting rabbit was minced and washed twice with two volumes of ice water The washed tissue was then ground with sand and extracted with an equal volume of *M*/15 sec phosphate which contained 0 2 per cent fluoride Aliquot parts (1 5 c c) were incubated in an oxygen atmosphere at 37° for 30 min

The phosphate analyses were calculated to mgm P in the entire extract

	O_2 uptake	P_{dir}	P_{alk}	P_{iod}	P_{merc}	P_{30}
Control (initial sample)		1 16	1 17	1 18		1 16
Incub without substrate	474	1 00	1 00	1 02		1 11
Incub with glucose 40 mgm	823	0 75	0 83	0 77	0 75	0 96
Incub with malate 15 mgm	720	0 78	0 78	0 98	1 00	1 12

P_{dir}	phosphate determined directly
$P_{alk.}$	phosphate after 20 min incubation in *N*/1 caustic soda
P_{iod}	phosphate after 20 min incubation in *N*/10 alkaline iodine
$P_{merc.}$	phosphate after 10 min incubation in neutral mercuric chloride
P_{30}	phosphate after 30 min hydrolysis in *N* 1 hydrochloric acid at 100°

The ester derived from malic acid has not been isolated, but since it is hydrolysed by mercuric chloride, which is a specific reagent for the hydrolysis of acetal esters, it is probably the phosphoric ester of the enolic form of pyruvic acid The phosphopyruvic acid could not originate from traces of sugars because fluoride inhibits the formation of this compound from phosphoglyceric acid The esterification product, however, contains no phosphoglyceric acid, since the P_{30} value indicates that no acid resistant ester is formed from malate. It therefore appears that the phosphopyruvic acid had its origin from oxalacetic or pyruvic acid derived from the oxidation of malic acid Malate is converted to carbohydrate in the kidney cortex[4], and it appears from these facts that phosphopyruvic acid is an intermediate in the formation of sugars from malate and lactate (cf Green[5], Meyerhof[6])

Diffusion of Phosphate Ions into Blood Corpuscles

WE find on shaking labelled (radioactive) sodium phosphate of negligible weight with blood, that phosphate ions quickly enter the erythrocytes In the course of three hours nearly half the phosphate ions present in the plasma of rabbit s blood diffuses into the corpuscles When labelled phosphate ion enters the cell, it becomes available for esterification processes Simultaneously non labelled phosphoric acid ester molecules decompose, producing non labelled phosphate which diffuses into the plasma, this process is going on incessantly There is thus a rapid interchange of phosphorus atoms between plasma and cells In *in vivo* experiments, using a newly developed technique[1], we find the same rate of penetration of phosphate ions into corpuscles as occurs *in vitro* In both cases, not all the acid soluble organic phosphorus compounds exchange their phosphorus for the labelled variety and it is of interest to note that a large part of the phosphorus esters which resist hydrolysis when heated for an hour at 100° with mineral acids do not become labelled in the course of a few hours

In order to compare the rate of diffusion of the phosphate ion and that of ester molecules, in some of our experiments we added labelled hexosemonophosphate (kindly presented to us by Prof Parnas) to blood We find that if hexosemonophosphate diffuses at all into cells, the rate is at least ten times less than that of phosphate ions In *in vitro* experiments, labelled hexosemonophosphate was found to be to a large extent decomposed, presumably by Robison's bone phosphatase present in blood The rate of hydrolysis is that of a monomolecular reaction, the velocity constant being 0 0024 $\min^{-1}$ The enzymatic decomposition of the ester also takes place in the absence of corpuscles In the intact animal, the blood comes in rapid and intimate contact with the large surface of bone tissue containing the enzyme and in *in vivo* experiments a rapid decomposition of hexosemonophosphate was observed In the course of an hour and a half, more than 99 9 per cent of labelled hexosemonophosphate injected into the vein of a rabbit left the circulation As mentioned in a previous communication[2] no labelled phosphatides, or at most only a minimal amount was formed in the blood, these substances being liberated from the liver and other organs into the circulation

A detailed report of our experiments is being published in the proceedings of the *Kgl Danske Videnskabernes Selskab Biol Medd* We wish to express our thanks to Profs Niels Bohr and Einar Lundsgaard for putting numerous facilities at our disposal and to Miss Hilde Levi for making the determinations of activity of the preparations

Bone Tumours and Œstrone

RECENT experiments on mice from our sarcoma strain are producing results of sufficient importance to be communicated now although the experiments are by no means complete

We have shown[1] that there is a very marked sex difference in the incidence of bone tumours 77 3 per cent of the females and only 29 6 per cent of the males dying from this cause The mean bone tumour age for females is 15 3 months and for males is 17 7 months, the youngest tumour bearing female was five months and the youngest tumour bearing male was six months old

In an attempt to increase the tumour incidence in males, experiments with œstrogenic compounds were begun less than three months ago Through the generosity of the Organon Laboratories, we were supplied with a number of 5 mgm tablets of œstrone Young males between three and four weeks old, each received one tablet implanted subcutaneously into the left flank

During this last week a number of these animals have shown symptoms of retention of urine causing death in two cases, five other mice were killed before the symptoms became too pronounced Both the dead mice had enlarged pituitary glands, but the others seemed to be normal in this respect All the animals were undersized, and showed atrophy of the genital organs, retention of urine seemed to be due to prostatic enlargement One mouse had bilateral hydronephrosis

Three of the animals which were killed had bone tumours, one had osteomata of the right femur and right tibia, another had an osteoma of the right femur and two osteomata on the ribs, the third had an osteoma on a rib and early neoplastic changes in the right femur These mice were all 3–3 5 months old, the implants had been in position for about 2 5 months Another animal of the same age showed signs of early neoplastic changes in the femora, and the fifth mouse, only two months old and implanted with a tablet one month previously, had definite alterations in the right femur It is impossible without microscopic examination to say anything concerning the bones of the two mice which died, yet they appeared to be abnormal All the bones suspected of neoplastic changes will be examined microscopically, but there may be some delay before this can be done, of the gross changes there is no doubt

The implanted tablets were recovered from each animal and weighed it was found that each mouse had absorbed 20 000–30 000 international units of œstrone

Painting experiments are also in progress in which the animals receive a much smaller dose of œstrone An adequate number of control mice is being kept so far these show no sign of tumour formation

It is not suggested that as is probable in the case of mammary carcinoma, these bone tumours arise directly by the action of œstrone on the tissues concerned In this respect it is worth noting that the sarcoma strain has a much lower incidence of mammary tumours (14 1 per cent) than its parent Simpson stock (50 73 per cent) Recent work by Cramer and Horning[2], Zondek[3], and others shows that there is a close relationship and balance maintained between the different endocrine glands and a large overdose of one hormone may upset the balance and alter the rate of hormone production in other glands These experiments may provide evidence as to which gland is responsible for the formation of the hereditary bone tumours

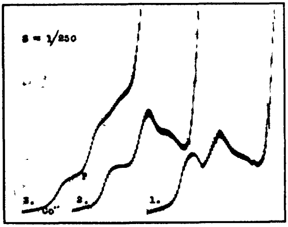
Polarographic Proof of Proteolysis in Diagnosis with Enzyme Reaction

DURING recent years, Fuchs's reaction has been widely applied for the diagnostics of malignant tumours Fuchs[1] has found that normal serum is able to decompose the fibrin prepared from carcinomatic blood on the other hand serum from a patient suffering from a malignant tumour decomposes the fibrin obtained from the blood of a normal individual He proved the proteolysis by the increase of the non protein nitrogen—a method proposed already by Abderhalden[2]—or by determining the ratio of carboxylic and amino groups before and after the proteolysis

The determination of the non protein nitrogen increase due to the proteolysis is the most delicate problem of this procedure, and often leads to difficulty in interpretating the experimental results On the basis of the polarographic investigations of proteins as carried out by R Brdička[3], a new way has been made possible by which the proteolytic cleavage can be followed exactly[4] Thus we applied Brdička's test which indicates the disulphidic or sulphydryl groups of proteins and their decomposition products, for the proof and measurement of the proteolysis

We followed in our experiments a modification of the original Fuchs reaction described by Chrometzka and Gottlebe[5], in which method the aseptic ultrafiltrate of the serum is used instead of serum We filtered the sera in the Tisen apparatus, which was carefully sterilized, through membrane filters "impermeable to proteins" and we used the filtrate for the modified Fuchs reaction It has been shown by the above-named authors that the proteolytic activity of the serum is increased when the serum is freed from proteins. A further advantage of using the serum filtrates consists in the fact that the liquid, after the proteolysis, does not need to be deproteinated Such a deproteination in the case of serum leads to the precipitation of higher proteolytic products with proteins, whereby the effect of the proteolysis is lessened.

We put 0·5 c.c. of the ultra-filtrate into each of three sterilized test-tubes The first sample served as a control, to the second sample 5 mgm. of fibrin prepared from the blood of a normal man was added, and to the third one the same amount of a carcinomatic fibrin After an incubation period at 37° C, the samples were filtered through a hard filter paper and a certain amount of the filtrates were mixed with an equal amount of the Brdička buffered cobalt solution These solutions were then submitted to polarographic analysis and the usual current-voltage curves were recorded. It should be mentioned that the fibrin filtrate alone does not show any protein reaction.



Polarographic evidence of proteolysis in the Fuchs modified reaction

Curve 1 Polarographic effect of the serum ultrafiltrate Curve 2 Proteolysis of carcinomatic substrate with carcinomatic serum (slightly positive) Curve 3 Proteolysis of normal substrate with a carcinomatic serum (strongly positive). The serum was taken from a patient suffering from Ca mammæ

The result of such an experiment is shown in the accompanying curves.

The first current-voltage curve, due to the ultra-filtrate in the Brdička buffered cobalt solution, proves that the membrane filter does let some small amount of protein substances, giving the Brdička protein test, pass through. Curves 2 and 3 are due to solutions of ultra-filtrates incubated with carcinomatic and normal fibrin respectively; in the test solution of ultra-filtrate where the proteolysis of fibrin took place, an appreciable 'double wave' (*P*)—the Brdička protein reaction—appears on the current voltage curve (see Curve 3), whereas in the ultra-filtrate which reacted with the corresponding substrate to a small extent only, this effect is slight (Curve 2). Thus it is evident that the proteolysis proceeds in both ultra-filtrates, but the effects differ in the height of the 'double wave' caused by the products of proteolysis Hence the height of this 'wave' indicates objectively the degree of proteolysis in a way similar to the determination of the increase of non-protein nitrogen, the latter method being beyond comparison more difficult from the technical point of view

From similar experiments—altogether fourteen have been carried out—it follows that the Brdička polarographic test for proteins and their decomposition products enables one to prove in a simple and exact way that proteolysis occurs in reactions of serum filtrates with substrates. A similar mode of procedure was used by Brdička and Klumpar[4] in their study of proteolytic cleavage of proteins with pepsin We believe that these findings will lead to far-reaching applications of the polarographic effect to various reactions based on the proteolysis of specific substrates It will be useful also for the study of different organic dysfunctions and physiological disorders

Colorimetric Determination of *dl*-α-Tocopherol (Vitamin E)

Investigations of Evans[1] and Karrer[2] have demonstrated that α-tocopherol possesses reducing properties, so that it can be determined by potentiometric titration with gold chloride

Our colorimetric determination is based upon the reducing power of α tocopherol against ferric chloride The ferrous salt which is formed has been determined by us with α-α' dipyridyl The reaction is carried out in ethanol and the red colour of the ferrous-dipyridyl complex has been determined with a Zeiss-Pulfrich photometer (screen 50 and 1 cm. cell). The quantities of α-tocopherol which have been determined varied from 0 01 to 0·4 mgm.

We also have determined α-tocopherol (Hoffman – La Roche) by Karrer's potentiometric titration with gold chloride, and the two methods give results in good agreement. In both methods carotene may cause difficulties

Details and applications will be published elsewhere.

Colour Reactions of Urine

A **sample** of urine containing about 2 per cent of free sulphuric acid and treated with certain oxidizing agents, as for example, potassium dichromate potassium permanganate, ammonium persulphate iodine or iron sesquichloride respectively (the latter two at a high temperature), produces a reddish pigment which may be destroyed even by a slight excess of those reagents A chromogen of urine which is responsible for this colour reaction is derived probably from some nutrient material for urine of carnivora (lion and wolf) develops only a brownish colour, while that of man and pig is an intense wine red and urine of herbivora (cow, horse and sheep), fed on a plant material containing photoxan[1], gives a rose red pigment[2]

This colour reaction may be very helpful in physiological investigations of metabolism, and also for certain diagnostic purposes

Dioxymaleic Acid Oxidase

In a previous paper[1] two of us reported on the existence of a vegetable dioxymaleic acid oxidase We wish to correct our statement that this enzyme is not sensitive to cyanide The function of this catalyst, prepared from sorrel (*Rumex acetosa* L) by acetone precipitation of the juice of the leaves is inhibited completely by 0 0001 *M* hydrogen cyanide at *p*H 4, where the enzyme has a sharp optimum Comparative studies suggest that this ferment is one of the three basic ærobic oxidases of the vegetable kingdom, the other two being the polyphenol and ascorbic oxidase The enzyme oxidizes the acid reversibly the H being oxidized to H_2O_2

Artificial Production of Uranium Y from Thorium

Artificial radioactivity induced in thorium by neutron bombardment has been studied by various authors[1] Meitner, Strassmann and Hahn[2] especially have recently published the results of their detailed investigations, according to which they ascertained the production of a thorium isotope ^{233}Th (26 min) and three isomers of a radium isotope ^{229}Ra ($<$ 1 min , 15 min and about 4 hours)

We have also been studying the same problem for some time, and so far as the above results are concerned, we seem to be in general agreement with the last-mentioned authors Besides these isotopes, moreover, we obtained another thorium isotope which we identified with uranium Y, the parent substance of protactinium, the thorium series thus being changed over to the actinium series

Thorium nitrate, carefully freed from mesothorium as well as from other disintegration products except radiothorium, was exposed to fast neutrons which were produced by bombarding lithium with 3 Mv deuterons obtained by means of our cyclotron After the exposure, which ranged from three to fifteen hours thorium was chemically separated from the sample This showed two periods of β decay, one of which we identified with that of ^{233}Th as above mentioned

The other period of 24 5 hours was surmised to be due to a thorium isotope which was produced from thorium through loss of neutrons This ought to give uranium Y according to the following reaction

$$^{232}\mathrm{Th} + {}^{1}n \rightarrow {}^{231}\mathrm{UY} + 2\,{}^{1}n$$

In fact the above period coincides with that of uranium Y (24 6 hours) in accordance with our supposition

The sign of the β rays was shown to be negative and the measurements of their absorption in aluminium gave an absorption coefficient of 246 per cm which is not very far from 300 per cm found by Antonoff, and lies between 52 95 and 585 per cm, given for two components by Erohova[3] All these facts support the above conclusion The detailed account of the experiments will be published elsewhere

We wish to express our thanks to the Japan Wireless Telegraph Company for the electromagnet and other pieces of equipment used for the cyclotron, and to the Mitsui Ho onkwai Foundation and Tokyo Electric Light Company for financial support

Magnetic Properties of Superconductors

Using a ballistic method, we have measured the magnetization curve of the superconducting alloy Au_2Bi , for a specimen built up of separate small crystals we obtained the curve in Fig 1 It will be seen that there is practically no 'tail' to the curve, and that the hysteresis is much less marked than for a typical superconducting alloy , in fact, the magnetic behaviour approximates to that of an 'ideal' superconductor Such hysteresis as there is, is probably due to very slight impurities in the specimen, rather than to the irregular shape, since a similar specimen made up of small irregular lumps of very pure tin (an 'ideal' superconductor) showed much less hysteresis

Since Au_2Bi is an alloy of definite composition (it is not soluble in either gold or bismuth[1]), this resemblance to the behaviour of an 'ideal' superconductor confirms the view that the anomalous

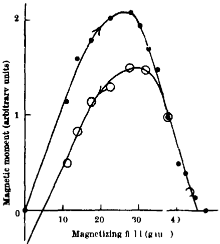

Fig 1

behaviour of superconducting alloys is due not to the fact that they are alloys but to some secondary cause such as inhomogeneity of composition

In Fig 2*a* we show the *H T* curve obtained for Au_2Bi, and it will be seen that the H_c values are considerably lower than those obtained in Leyden from resistance measurements on the Au Bi eutectic[2] and that the transition temperature of our specimen (about 1·73° K) is lower than that found in Leyden (1·84° K) These discrepancies may be due to the presence of very fine threads of Au_2Bi (separated from each other by free bismuth) in the eutectic, which, on account of their thinness may perhaps remain superconducting at higher fields and temperatures than the crystals used in our measurements

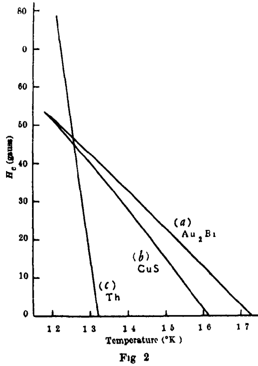

Fig 2

We did not succeed in obtaining ideal behaviour in the case of the superconducting compound CuS (this may have been due either to insufficient purity of the constituents, or to the presence of Cu_2S in our specimens), although there was a marked hysteresis, the 'tails' of the magnetization curves were not very pronounced, and it was possible to determine the critical field at different temperatures The $H_c T$ curve is shown in Fig 2*b*, and the transition temperature (1·61° K) agrees with that found by Meissner[3] It will be noticed that both Au_2Bi and CuS have low values of dH_c/dT, of the same order of magnitude as the soft group of superconductors[4], this may be connected with the fact that in the case of both these alloys the two components lie immediately on one or the other side of this group in the periodic system

While testing the measuring apparatus we measured also the $H_c T$ curve of thorium (not previously measured) shown in Fig 2*c* As with all the other hard superconducting elements dH_c/dT is considerably higher than for the soft superconductors[4], and also (probably due to impurities) the magnetic behaviour resembles that of a typical alloy rather than of an 'ideal' superconductor The difference between the transition temperature of our specimen (1·32° K) and that found by Meissner[5] (1·49° K) is probably due to difference of purity

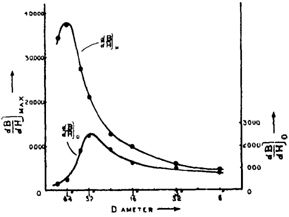
Magnetic Quality of Iron Wire as influenced by the Diameter

In a previous note[1] the results were given of tests on Armco iron wire of various diameters when heated in hydrogen to a condition of maximum permeability at a temperature of 1 200° C A number of the magnetization curves so obtained have been analysed and the values of the maximum slope $\left.\frac{dB}{dH}\right]_{\max}$, and



also the values of the slope at the origin, $\left.\frac{dB}{dH}\right]_0$, respectively, have been plotted as a function of the diameter of the wire In this way the two curves shown in the accompanying graph have been obtained

Each of the curves has a well defined maximum value, and the general character of each curve can be accounted for if it be assumed that (i) the wire has a magnetically hard surface layer, (ii) the process of magnetization commences at the surface of the wire and proceeds progressively towards the axis by a kind of chain effect, so that the magnetic induction is greatest near the surface and progressively decreases towards the axis of the wire

Further tests are being carried out at higher temperatures, and a full account of the results will be published elsewhere in due course

Diffraction Patterns Produced by Surfaces in Sunlight

THE reflection of sunlight from various surfaces, including those of finger nails, skin, paper wood, plant leaves, and glass slides covered with thin films of dried blood, produces mosaic like varicoloured patterns which yield to the unaided eye an impression of the presence of many small but discrete coloured granular particles The coloured mosaics are particularly brilliant when the surfaces are viewed near grazing incidence, although in some instances the effect is clearly evident from other angles Such patterns are not evident on the polished surface of glass The optical irregularity of the former surfaces is commonly evident to the unaided eye only by the generalized cloudiness or haziness The mosaic pattern is readily seen when the reflecting surface, adjusted to an appropriate angle, is placed at a distance of approximately four to fourteen inches from the eye At greater distances the detail of design is lost At lesser distances the chromogenic features are not apparent An illusion of flow of the coloured 'particles' is produced by slight tilting of the surface while under observation It thus appears as if different groups of surface projections come into play with a resultant rearrangement of the coloured spots

The production of coloured patterns by reflection of white light from surfaces is a commonly recognized phenomenon However, the mosaic effect produced by the above mentioned surfaces is different, in appearance at least, from those which have been described previously Among the well known colour effects produced by reflection are the colours of striated surfaces and the colours of fine laminar structure The former, usually seen as a pattern of concentric rings upon the finely scratched surface of glass and metal, was attributed by Tyndall[1] to interference of light reflected from the opposite sides of the furrows or scratches The coloured areas seen in certain shells and pearls are associated with fine laminar structure and are attributed to the class of phenomena associated with Newton's rings There is a conceivable similarity of the colours of the mosaic to those produced by reflection of light through multi layers of surface films spread on metal plates[2], except that in the former instance the areas of a given thickness are extremely small and the reflecting foci are tilted at different angles, hence the mosaic like effect

The fact that the mosaic effect appears in sunlight and in light from distant incandescent lamps, while not in light originating from a nearby source, suggests that the phenomenon is to be classed with the Fraunhofer diffraction phenomena[3]

The mosaic pattern is apparently a consequence of the mutual interference of diffraction bands produced when parallel light rays strike the small component parts of certain surfaces This regularity of the chromogenic interference mosaic for certain materials provides additional means of characterizing the structure of such surfaces

Cause of Earthquake Ruptures

AT present there is no established theory of the cause of earthquake ruptures because of their diversity Observations in Cordoba of the San Luis shocks of May 1936, including records on a sensitive Richard barograph at the National Observatory, have suggested that this diversity of behaviour is due chiefly to differences of depth, of dip and strike of the faults, and that barometric pressure is often the final actuating cause which determines the hour and perhaps the day

Actual cracks observed in the surface in many places confirm that the underlying conditions in the tectonic type of earthquake is an accumulation of strains along geological faults in the earth's crust, the sudden release of which produces the shock Whatever the position and direction of these strains, the gravitational pressure of the masses must tend to hold the surfaces together Without gravitational pressure, no strain could accumulate A sufficient *release* of such pressure will cause a rupture Confirmation of this is found in the cases where shocks have occurred chiefly at low tide

Tidal stresses caused by the sun and moon are alone capable of effectively decreasing these pressures Nearly all extensive series of observations have disclosed a slight preference for times of new and full moon The San Luis earthquakes referred to suggested that in deep shocks, where the gravitional pressure of the mass above was greatest, the connexion was closer than in shocks nearer the surface

To test this point, the most destructive shocks, fifty-nine in number, in the past three centuries, for which data could be found, and forty heavy shocks reported in the past two years, were examined In both these groups, approximately eighty per cent showed preference for the times of new and full moon

These same shocks showed a preference for the times of lunar perigee Extensive series of after-shocks in the disastrous earthquakes of 1891 in Gifu and 1897 in Assam show preferences during several months for the times when new and full moon occurred near perigee.

These facts establish a definite relationship with sun and moon which can only be interpreted as gravitational. From its nature gravitation, if present in some cases, must be present in all whether its effects are directly noticeable or not. Differences of dip and strike in the faults can account for deviations from new and full moon. Evidence confirmatory of this explanation is found in the Inverness earthquake of 1901 and those generally in Calabria and Japan.

Existing evidence appears sufficient to establish the thesis that *the ruptures due to earthquake stresses about geological faults are due primarily to the gravitational action of the sun and moon*

Shocks recorded in Cordoba during or just after sharp diurnal or sporadic 'lows' of the barometer suggest that these are the final controlling factor which in many cases determines the hour and even day.

A gravitational theory permits the prediction of the majority of heavy destructive shocks within two or three days

Biological and Cytological Observations on Tenthredinid Parthenogenesis

During the past three years, I have made certain findings regarding two species of Tenthredinidæ, and as their detailed publication will be delayed owing to my departure abroad, I take the opportunity to state them briefly

It is well known that the species *Pristiphora pallipes* Lep reproduces by thelytokous parthenogenesis but very occasionally produces males. The chromosome constitution of the female is 16, as determined from oogonia, follicle cells, and embryo cells, that of the male appears to be 8, from spermatogonia and second spermatocytes

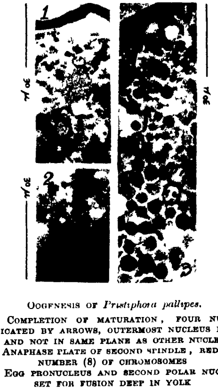
In oogenesis there are two maturation divisions (Fig 1) That reduction takes place in the first division is indicated because 8 chromosomes are found in the second anaphase (Fig. 2). These chromosomes appear double at times and this, along with the fact that the second division follows immediately after the first, can be taken to mean that the chromosomes are split ready for this second, equational, division. The result of these divisions is that four nuclei are formed in line (Fig. 1) Later, the female pronucleus and second polar nucleus approach and lie pressed together, deeper in the yolk, as if for fusion (Fig. 3).

These facts therefore indicate that egg maturation is similar to that of normal bisexually reproducing animals, and that the diploid condition is restored by fusion of egg pronucleus and second polar nucleus, a condition comparable to that already known in certain other animals showing obligatory (for example, *Artemia*), facultative (for example, *Lecanium*), and experimental (for example, *Asterias*), parthenogenesis The maturation appearances up to the four nuclear stage are similar to those figured by Doncaster[1] for *Pteronidea* (*Nematus*) *ribesii* Scop., but my findings regarding the fusion of the female pronucleus and the second polar nucleus are new.

Further support for my interpretation is seen from such details of the prophase stages of meiosis as I have worked out, leptotene, synizesis, and pachytene all appear to be normal, although the pairing of chromosomes has not yet been detected with certainty

An interesting fact concerning the first polar nucleus is that in several cases spindles have been observed which, from their position, appear to be the fusion product of the daughters of the first polar nucleus The appearances are similar to Doncaster's 'fusion nucleus', which he considers is formed from the second polar nucleus and the inner daughter of the first polar nucleus.

More than 1,700 eggs were examined, about 943 (54 per cent) proving of use Of the latter, 191 gave first division stages, 106 those of the second division, 254 the four nuclei stage, and 94 gave fusion stages. The other 298 are as yet unclassified



Oogenesis of *Pristiphora pallipes.*

1 Completion of maturation, four nuclei indicated by arrows, outermost nucleus faint and not in same plane as other nuclei.

2 · Anaphase plate of second spindle, reduced number (8) of chromosomes

3 Egg pronucleus and second polar nucleus set for fusion deep in yolk

A 'gynandromorph' showing complete male external genitalia and almost complete but distorted female external organs was also found. The gonads and internal genitalia were male in appearance. Again, a larva, the gonads of which were female in gross appearance, contained what appear to be male cells.

In the second species, *Priophorus tener* Zad., rearing experiments with six unmated females from wild larvæ gave only males However, three other unmated females from wild larvæ produced only females (six larvæ and seven flies), and from four of these another generation of parthenogonic females (four) was obtained. The oogonia showed 12 chromosomes and the spermatogonia 6. The mechanism of chromosome number control is unknown in this case. This adds another example to the few species already known to be not exclusively arrhenotokously or thelytokously parthenogenetic[2] It is evident that the biology of saw flies will well repay further study

Thanks are due to Prof A D Peacock, under whose supervision I have worked for the provision of certain material to Dr Ann R Sanderson for the benefit of her experience in similar work and to Mr A T Baxter for laboratory assistance

Nitrogen Fixation by Blue Green Algæ

IN India rice is grown on the same land for many years without the addition of manures to the soil Preliminary experiments have shown that a considerable amount of nitrogen is fixed in the soils of the rice fields under water logged conditions when there is an abundance of algal growth (especially Blue green Algæ) present With the object of investigating the role of the Blue green Algæ, a number of species of *Anabæna* as well as *Phormidium foveolarum* were isolated in unialgal culture from the soil of an Indian rice field The last as well as three species of *Anabæna* were afterwards obtained in pure culture altogether devoid of bacteria and other contaminating organisms by a method analogous to that employed by Pringsheim (1913) These cultures have been tested by the Bacteriological Department at the Rothamsted Experimental Station and pronounced free from bacteria

Inoculations from these pure cultures grown in mineral solutions lacking nitrogen (apart from that contained in minute traces of soil extract), showed that, while the *Phormidium* has no capacity for fixation of nitrogen, the three species of *Anabæna* are able to fix considerable quantities averaging 3–5 mgm of nitrogen per 100 c c of medium in about two months The amount of nitrogen fixed by the Algæ in the presence of *Azotobacter* and other bacteria is the same as in the pure cultures from which it appears that bacteria play a relatively unimportant part in nitrogen fixation in the rice fields

The effect of the presence of various organic compounds on the process has been examined Certain soluble carbohydrates (arabinose maltose raffinose inulin and dextrin) have a decidedly inhibiting effect on nitrogen fixation, but the process will go on in the presence of soluble nitrogen compounds Iron is not essential for nitrogen fixation

Diverse workers (Molisch 1926, Vouk and Wellisch 1931, Copeland 1932) have previously affirmed nitrogen fixation by Blue green Algæ, but the evidence as to the purity of their cultures is not adequate Drewes (1928) and Winter (1935) used several bacteriological agar media to test the purity, but the evidence is inconclusive, since on such media in the presence of Algæ, there may be no visible growth of bacteria although present A similar criticism applies to the researches of Allison and co workers (1932 and 1935)

Normal Dentition of Sharks

WHEN the teeth of the various rows in the jaw of *Carcharias melanopterus* at different ages are compared, one observes an exposed row of teeth slightly smaller than the unerupted ones behind it and incomplete hindermost rows of what appear to be vestigial remains of teeth which can never come into use Mr G P Whitley, of the Australian Museum, has kindly referred me to Gudger and Smith s memoir[1] on the most primitive shark *Chlamydoselachus*, and notes unfortunately the problem of their replacement has not been touched upon else considerable light might have been thrown on the matter From fossil sharks too there are no apparent data on this point

In this memoir which I have seen from the South African Museum the small teeth of *Chlamydoselachus* are regarded as employed for retaining the food that is seized rather than for chopping off pieces like the broad teeth of *Charcharodon* and *Galeocerdo*

If the exposed teeth of these latter were constantly shed and replaced from the unerupted teeth one would expect to find in an adult the largest teeth exposed or lacking in seriation through constant use

Mesotron (Intermediate Particle) as a Name for the New Particles of Intermediate Mass

THE existence of particles intermediate in mass between protons and electrons has been shown in experiments on the cosmic radiation[1] Since at present so little is known concerning the properties of these particles, for example the exact value of the mass the laws governing their production their stability against disintegration etc it may yet be too early to assign to them a name But inasmuch as several names have already been suggested, namely dynatron penetron barytron, heavy electron yukon and x particle it may be wise to consider the matter at this time

The property which so far serves to distinguish the new particles from the other two types of particles which carry the same magnitude of electric charge, namely the proton and the electron seems to be the magnitude of their mass Although from the experiments so far performed it is not possible to say definitely whether the new particles exist with a unique mass only, or whether they occur with a range of masses it does appear quite certain that the mass, whether unique or not is greater than that of an electron and less than that of a proton One must consider then three types of particles all carrying electric charges of equal magnitude electrons, the new particles and protons We should like to suggest therefore the word mesotron (intermediate particle) as a name for the new particles It appears quite likely that the appropriateness of this name will not be lost, whatever new facts concerning these particles may be learned in the future

Free Radical Terminology

SOME confusion appears to be creeping into the literature with regard to the designation of molecules which function as free radicals Some authors for example, describe methylene $H_2C=$ as a diradical and the next step presumably will be to term methine $HC\equiv$ a triradical This is certain to lead to confusion, since methylene contains a carbon atom with an electron sextet, while a diradical such as $-CR_2-CR_2\ CR_2-$, contains two carbon atoms with an electron septet or free valence Accordingly, methylene with its electron sextet should be regarded as a bivalent radical It is true that oxygen, in virtue of its high paramagnetism is considered to be a diradical but this refers to the oxygen molecule, O–O–, with each atom carrying a free valence

The terms odd molecule' and even molecule have now lost much of their original significance, since we are now familiar with even numbered diradicals and also with charged molecules containing an unpaired electron Thus the molecule

$$R_3C\ \underset{|}{C}H-CH_2\ CH_2$$

is an even molecule since it contains an even number of electrons In view of the fact that it is both an ion and a free radical it is conveniently termed an 'ion radical' This serves to avoid confusion with the terms radical ion and ionized radical, which have long been in use to designate the triarylmethyl ions, R_3C^+ and R_3C and inorganic ions such as NH_4^+ and ClO_4

Points from Foregoing Letters

A TABLE showing the amount of phosphate which enters into combination, in presence of oxygen, when glucose or malate is added to minced kidney cortex of a fasting rabbit, is given by Dr H Kalckar The author concludes that malic acid is oxidized to pyruvic acid which combines with phosphate to form phosphopyruvic acid, as an intermediate step in the synthesis of sugars

Experiments with labelled radioactive phosphate injected into the blood stream show, according to A H W Aten, jun, and Prof G Hevesy that there is a rapid exchange of phosphorus atoms between plasma and cells that is, between inorganic phosphate and the phosphoric ester in the red blood corpuscles Hexosemonophosphate penetrates the cells less rapidly but is decomposed within an hour in the blood stream by an enzyme derived from the bones

F C Pybus and Miss E W Miller report that œstrone tablets, weighing 5 mgm each, were implanted subcutaneously into young male mice belonging to a strain in which 77 3 per cent of the females and 29 6 per cent of the males develop bone tumours Three of these mice have developed osteomata at the age of 3–3 5 months, 2 5 months after the tablets were implanted, the bones of two others showed definite early changes The average tumour age in males is 17 7 months, and the earliest tumour in an untreated male appeared at the age of six months

A M Kotljar and V Podroužek submit polarographic curves' indicating that the method can be conveniently used to detect the products of protein break up, such as are formed when normal serum is added to fibrin from a cancer patient, or vice versa

By exposing thorium nitrate to fast neutrons, obtained by bombarding lithium with 3 Mv deuterons, Dr Y Nishina, T Yasaki, Prof K Kimura and M Ikawa have produced a radioactive substance with half-period and beta ray penetrating power identical with those of uranium Y, parent of the protactinium series

The magnetization curve of superconducting Au_2Bi has been measured by Dr D Shoenberg, and it is found to resemble that of an 'ideal' superconducting element rather than that of a typical alloy Since Au_2Bi, unlike most superconducting alloys, has the same composition and structure throughout its volume, it is inferred that the anomalous properties of most superconducting alloys are connected with inhomogeneity rather than with the fact that they are alloys

The relationship between the diameter of iron wire and the maximum slope and the initial slope respectively, of the magnetization curves after the wires had been heated to a condition of maximum permeability have been obtained by Dr T F Wall The results obtained imply that the process of magnetization commences at the surface and proceeds progressively towards the axis

Out of 59 major earthquakes during the last 300 years, eighty per cent occurred at the time of new or full moon C D Perrine considers this as evidence in favour of the view that the time when ruptures due to earthquake stresses about geological faults take place is determined by the gravitational action of the sun and moon the tidal action of which brings about the rupture by releasing the pressure

L C Comrie finds in the thelytokously parthenogenetic saw fly, *Pristiphora pallipes* Lep that the diploid number in the female is 16, that in the rare male 8 In oogenesis there occur two maturation divisions, reduction, and the subsequent juxtaposing of pronucleus and second polar nucleus, which usually indicates that diploidy is restored by fusion of these nuclei Two sexual abnormalities have been found In the species *Priophorus tener* Zad, both arrhenotokous and thelytokous parthenogenesis have been discovered, the female and male counts are 12 and 6 respectively

Prof F E Fritsch and P K De report that pure cultures of the Blue-green Alga *Anabæna* found in Indian rice fields, has been shown to have the property of fixing nitrogen from the air, and they claim that this is the first conclusive proof of the ability of a Blue green Alga to do so

Dr S T Bowden directs attention to the confusion which is prevalent concerning odd and even molecules, and the application of the terms radical and diradical He suggests that a molecule carrying both a charge and a free valence be called an ion radical in order to distinguish it from the ionized radical and radical ion

Research Items

Indian Culture and the Native States

PROF. L. F. RUSHBROOK WILLIAMS, in an address to the Royal Society of Arts on the cultural significance of the Indian States (*J. Roy. Soc. Arts*, **86**, Sept. 16, 1938) stressed the position of the States as embodiments of traditional Indian conceptions of socio-political organization, and hence important for the rightful understanding of India's political development. No Government has ever ruled the country from a single centre. Under every Indian empire there have been numerous subordinate kingdoms performing many of the most essential functions of government in territory nominally under imperial control. There are certain fundamental differences between the Western and the Indian views of the State. In Indian ideas, the State deals with the individual, not as such, but as a member of overlapping communal or local groups carrying out many forms of corporate action, which the State cannot compass but essential for the well-being of the citizen. Hence India is a country of communities—village communities, castes or guilds, and the joint family—and it is only recently that the State has taken over such functions as police, education, or poor relief. Before British rule, the State scarcely came into contact with the individual. The political separatism resulting from these social institutions has been powerfully reinforced by the different cultures, races and languages, which have poured into India since historic times. The subordinate States have played an important part in crystallizing these socio-political institutions, and as supporters of the traditional arts of India which, but for them might have perished in the pursuit of Western ideas and culture under the British *raj*.

Properties of the Protoplasmic Membrane

IN a recent review of the literature, Harvey and Danielli (*Biol. Rev.*, 13, 319; 1938) propose a relatively simple model of the surface layers of the cell, based on their physical properties. The tension of the surface lies between 1·0 and 0·1 dynes/cm., which is too low for a simple oil-water interface. The presence of an adsorbed protein film is shown, however, materially to reduce the interfacial tension. On this and other grounds, it is suggested that the surface of the cell involves, as a minimum, a bimolecular layer of lipoid molecules between two layers of protein molecules. Measurements of the thickness of the surface film (about 50 A.), of its permeability, and of its wetting properties are found to be compatible with this model. A simple explanation is given of the Na-Ca type of antagonism in terms of the acidic groups of the protein and lipoid films. Thus, on the alkaline side of the iso-electric point of the membrane cations will be adsorbed to form salts. It is well known that water is less soluble in the calcium salts of the probable active groups (carboxyl, phosphate, sulphate) than the sodium salts. High temperature coefficients of penetration are also explained without the necessity of the intervention of chemical processes. The membrane allows for preferential absorption of lipoids, and for pore and mosaic effects.

Histamine and Tyramine in Lung Diseases

J. L. HERRENSCHMIDT (*Thèse de Paris*, No. 634, 1938), has made a study of histamine and tyramine in the blood of thirty-one cases of respiratory disease including pulmonary tuberculosis, and comes to the following conclusions: (1) Severe ulcero-caseous tuberculosis is as a rule accompanied by an excess of tyramine and a normal amount of histamine in the blood. (2) In cases of tuberculosis complicated by hæmoptysis, involvement of the pleura or allergic or cutaneous manifestations, there is little change in the tyramine content but always an excess of histamine in the blood. (3) Broncho-pulmonary suppuration is usually associated with a rise of tyramine and in many cases also of histamine in the blood, and there is always an appreciable or considerable proportion of these two substances in the sputum. (4) In tumours of the lung there is always a considerable quantity of tyramine in the blood. (5) In asthma there is a large quantity of histamine in the blood during an attack and a normal quantity apart from the attacks. The tyramine is normal throughout.

Synthetic Preparation of Ephedrine

THIS alkaloidal drug is obtained from a shrub growing in a small area near Tientsin, China, and since the recent hostilities in China its price has fluctuated widely. Thus attention is directed to efforts to synthesize the drug, upon which Dr. J. Kamlet of the Israel Zion Hospital, New York City, reported (according to Science Service) at the meeting of the American Chemical Society at Milwaukee in September 1938.

Maturity of Salmon Parr

IT has long been known that male salmon parr may mature before leaving the river. These fish were regarded by some as precocious males and it was not known to what extent maturity was normal. An examination of parr has been made recently in the Welsh Dee (J. H. Orton, J. W. Jones and G. M. King, "The male sexual stage in Salmon Parr (*Salmo salar* L. juv.)", *Proc. Roy. Soc.*, B, **125**, 103-114, 1938). The results showed that 40 per cent of the population of two- and three-years old salmon parr became sexually mature in October 1937. Successful fertilizations were made in November. There is some indication that the parr spawn on the redds before migrating to the sea as smolts. It is suggested that all or most of the males normally attain their first sexual maturity in the river before migrating to the sea. This interesting observation should be followed up by similar work on other rivers.

Insects in Petrified Wood

EVIDENCE of ancient insect activity has lately been brought to light in the fossilized logs of Triassic age found in the Petrified Forest National Monument, Arizona, U.S.A. In many of these fossil trees there are ridges, channels and tunnels which seem to represent the burrows of larvæ of certain beetles. Some of these are channels just under the bark and appear to be the work of Scolytidæ Others take the form of tunnels into the heart wood and are perhaps the work of Buprestid or allied beetles The only species of tree attacked is *Araucarioxylon arizonicum*, and it seems probable that many were killed as the result of girdling by the Buprestid beetles A short account of these fossilized remains has recently been published by Mr M V Walker (*Proc United States Nat Mus*, 85, 137–141, 1938), who classifies them into four new genera

Biology of the Cockroach

THE life history of the very common and cosmopolitan *Blatta orientalis* L has long remained very imperfectly known A contribution towards a knowledge of this subject by Dr M A H Qadri has recently appeared (*Bull Entom Res*, 29, 263–276, 1938) Breeding of the insect was at a constant temperature of 27 5° C It appears that the œthecæ are normally laid in May and June and the time taken for the emergence of the first nymphs is from seven to ten weeks At the time of its escape from the œtheca the insect is in the so-called pronymph stage which has been overlooked by most observers It lasts but a few minutes, after which the first ecdysis takes place There are six true nymphal instars and at the seventh ecdysis change into the adult occurs The average developmental period, after exit from the œtheca up to the adult stage, is 279 days The formation and structure of the little known spermatophore is described together with the changes during development of the male gonads and their associated parts

Leaf Abscission in Healthy and Diseased Leaves of *Picea*

A H Campbell and A E Vines have re-examined the abscission mechanism in *Picea excelsa* (*New Phyt*, 37, No 4, October 1938) It has long been known that this abscission mechanism is actuated by the drying of the leaf, the structural features associated with abscission having been present in the leaf from a very early stage in its development The authors give grounds for attributing abscission not merely to the loss of water from the leaf but also to its relatively rapid loss In these circumstances, hygroscopic movements are set up in a thick walled hyaline layer at the base of the leaf, as the water loss is apparently greater from this layer, in which hygroscopic movements result, than from the leaf cushion, and the tissues separate in this region The cause of the water deficit in the leaf, it is suggested, may be wound gum deposits in the tracheids, these are seen after leaf fall but their presence just prior to leaf fall has still to be established In one form of the disease attacking spruce needles, *Lophodermellina macrospora*, the infected leaves remain attached to the tree The authors show that in this case the stomata on the infected leaf are blocked by substomatal sclerotia formed by the fungus hyphæ which, on the evidence of porometer experiments, may be expected to reduce materially the water loss from the leaf, and thus throw out of action the drying mechanism upon which leaf abscission normally depends

Anthracnose of the Watermelon

THE watermelon plantations of Egypt cover about fifty thousand acres, the produce of which is damaged to the extent of several thousand pounds each year by the fungus *Colletotrichum lagenarium* Dr Amin Fikry has given the results of his researches into the incidence and control of this disease in a recent paper (Min Agric Egypt, Mycol Sect, *Bull* 190, Govt Press, Bûlâq, Cairo Price P T 4 1938) The fungus causes leaf spotting or anthracnose upon a wide range of varieties, and symptoms usually appear when the plants are about two months old Almost complete control of the disease has been accomplished by dusting twice with sulphur The crop must be treated first as soon as the fungus appears, and again three weeks later Symptoms and control are illustrated in the bulletin by ten half tone plates

Past Seismic Activities in Japan

THIS subject has recently been reconsidered by Prof Akituno Imamura (*Japanese J Astro and Geophys* 15, No 3, 1938) He examines chiefly the activity in Honsyu and Sikoku since the earthquake history of Taiwan dates only as far back as A D 1655 The principal catalogues used in the work are the Dainippon Disin Siry (*Reports Imp Earthq Inv Comm*, 46, 1904) and Omori's catalogue (*ibid*, 88 *B*, 1919), both going back as far as A D 416 The authenticity of the reports of earthquakes mentioned in these catalogues is weighed with records of volcanic outbursts and also with records of tunamis Imamura considers that the catalogues do not omit any great earthquake though small ones may not be mentioned It appears that since A D 416 there have been three great periods of seismic activity in Japan namely, between the years 684 and 887, between 1586 and 1717, and since 1847 continuing at the present time The table of earthquakes divided into four intensity classes which are defined, and the maps of epicentral regions during the three periods, are very valuable additions to the paper

Storms in the China Sea

A PAMPHLET entitled The Law of Storms in the China Sea by C W Jeffries and G S P Heywood has been produced to replace an earlier publication of the Hong Kong Observatory The earlier work appeared in 1904 under the title ' The Law of Storms in the Eastern Seas and was written by W Doberck, formerly director of the Observatory The need for revision arose partly through the virtual disappearance of the large sailing ships, which made a large part of the text of the earlier work meaningless, and partly through the increase of information available about the storms, these it need scarcely be said are the dreaded typhoons of the Far East The present work contains synoptic charts showing part of the life histories of some typhoons of recent years and some typical barograms obtained at the Observatory during the approach and recession of storm centres at various distances, with a curve of normal daily pressure variation for comparison The most interesting and valuable part, however, is the section dealing with the precursory signs of the approach of a typhoon from the point of view of a forecaster at Hong Kong Swell is noted sometimes 1,000 miles from the centre, it moves outwards from the centre and gives a fair indication of the position of the centre, besides being probably the earliest indication of its approach It is interesting to note that the barometer is not an unfailing guide to the near approach of a storm centre, an example being the disastrous typhoon of September 18, 1906, which gave no definite barometric indication of its proximity four hours before it was at full strength in Hong Kong harbour Microseisms are also unreliable as premonitory signs

Research on Safety in Mines

THE sixteenth annual report of the Safety in Mines Research Board* including a report on matters dealt with by the Health Advisory Committee has been published recently by the Mines Department

In Part I a reference is made to the award by the Institution of Mining Engineers of the Medal of the Institution to Prof R V Wheeler (director of the research stations) in recognition of his eminent services in the application of Scientific Knowledge and Research to industry with special reference to problems of health in coal mining and of the Utilization of Coal

In order to promote interest in safety work each year large parties of miners are invited to visit the Research Station at Buxton to see large scale coal dust explosions and last year on each Sunday during the summer these demonstrations were given The Annual Conference of Mining Teachers was held at Buxton so that modern methods of research and the latest information could be given to them on safety matters About eighty mining teachers together with representatives of the Board of Education and of the Mines Department attended this conference Addresses were given on the following subjects Education and the Mining Engineer , Films and their Use for Instructional Purposes and Haulage Investigations

For many years stone dusts have been used for suppressing explosions by sprinkling the dust on the roof, sides and floor of the roadways in the mine The dusts used for this purpose have been obtained from shales, limestone and gypsum In the report the importance of special material of higher efficacy than the usual stone dusts is mentioned, and the results of the research on this subject are given It appears that common salt is the cheapest and most effective of these materials Unfortunately, this material would not fulfil its purpose if exposed to atmospheres of more than 70 per cent relative humidity, on account of its tendency to cake Experiments with various mixtures have shown that the tendency of powdered crude common salt to cake is much reduced if it is mixed with 20 per cent of finely ground talc (French chalk), precipitated chalk (whiting) or coal Its caking is entirely prevented by the presence of 10 per cent of tricalcium phosphate or 5 per cent of magnesium carbonate levis Equally good results were obtained more cheaply with only 2 per cent of magnesium carbonate and 20 per cent of talc or precipitated chalk

Tests have been made with mixtures of salt, talc and magnesium carbonate under standard conditions of test in a gallery at Buxton 4 feet in diameter, and the calculated efficacy of the salt present in the mixture is approximately ten times that of shale

In the report for 1936 stress was laid on the importance of choosing a dust of high and lasting dispersability It has been found that the finer particles are not dispersed as separate particles, and that a dust can be too fine A dust of fineness between 50 and 70 per cent through a 240 mesh B S test sieve containing about 20 per cent of fairly coarse particles over 60 mesh is recommended

In all mines where coal is won, firedamp is given off This is diluted by passing pure air round the workings But if the ventilation is impeded, the percentage of firedamp present in the mine atmosphere may increase or an excessive and unusual amount of gas may be given off for possibly a short period

It is desirable therefore for the mine manager to have information about the percentage of firedamp in the return air In the past this has been done by analysing spot samples by means of a Haldane or Bone and Wheeler apparatus The principle which is used for this purpose is to burn the combustible gas and measure the contraction produced

A very ingenious firedamp recorder is described capable of giving a continuous record of the percentage of gas present in the atmosphere over a period of a few weeks The electric current for the combustion chambers is supplied by a small generator, and the mechanism is arranged to control a sufficient number of these chambers to obtain almost a continuous record The principle used is similar to that of the Haldane apparatus, except that the control is mechanical and does not require constant attention

The belief is expressed that due to the development of the principle of sheathing explosives, and research on their compositions freedom from ignition underground will be assured It is significant that last year no ignition of gas occurred and many collieries were using sheathed explosives

A sheathed explosive consists of the ordinary bobbin of explosive contained in waxed paper but surrounded by an extra layer of sodium bicarbonate This bicarbonate is either held in position by a further layer of paper or it consists of a paper felt impregnated with sodium bicarbonate When the shot is fired, the hot gases which are produced are wholly enclosed in a cloud of fine particles of this inert material, and cooling of the gases takes place so rapidly that there is very little danger of ignition of firedamp

The obvious need for personal protection has been realized during the last few years, but at first considerable scepticism was displayed by managers and workmen with regard to the use of various items of apparel It has been proved that many men have escaped serious injury due to the use of hard hats, gloves, shin guards, knee pads, safety boots and goggles fitted with safety glasses The importance of this subject cannot be over stressed, and much thought has been given to the production of these articles More than 147,000 hard hats were supplied during the year, making a total of some 435,000 for the past three years

Many of the special appendixes are reports of the district investigators on researches on the problem of falls of ground These investigations are carried out under the direction of committees of local mining engineers, and a large amount of information is being collected on this extremely important subject

---

Some Oxidation-Reduction Reactions

THE dihydric phenol catechol, 1,2-$C_6H_4(OH)_2$, has been widely used as a substrate in the study of the enzyme action of an oxidase, and it has been supposed that the utilization of molecular oxygen during the respiration of certain types of plants is largely dependent on such action. It was shown by Robinson and McCance in 1925 and others that the enzymatic oxidation of catechol involves the absorption of two atoms of oxygen per molecule of dihydric phenol, and it has been definitely established that *o*-benzoquinone is one of the initial products of the action of a phenolic oxidase such as tyrosinase on catechol. The conversion of catechol to *o*-benzoquinone theoretically requires only one atom of oxygen, and the fate of the second oxygen atom has been the subject of controversy. Since aerobic oxidations are often attended by the initial formation of hydrogen peroxide, it was suggested that the second oxygen atom was converted into hydrogen peroxide:

$$C_6H_4(OH)_2 + O_2 = C_6H_4O_2 + H_2O_2$$

Onslow and Robinson, and Platt and Wormall, claimed to have detected traces of hydrogen peroxide in the enzymatic oxidation of catechol, and they attributed the difficulty of detecting this substance to its decomposition by peroxidase and catalase in the enzyme preparations. Others suggest that the decomposing activity of small amounts of some metals accounts for the removal of peroxide. Doubts have also been expressed as to the formation of hydrogen peroxide. Pugh and Raper in 1927 pointed out the possible decomposing action of catalase, and they suggested that the second oxygen atom might act by further oxidation of the *o*-benzoquinone. Nobutani in 1936 found that catalase has no effect on the oxygen consumption during the enzymatic oxidation of *p*-cresol, 1,4-$CH_3.C_6H_4.OH$, and hence concluded that hydrogen peroxide is not formed in this reaction.

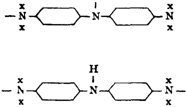
C. R. Dawson and B. J. Ludwig[1] consider that the conclusions of Pugh and Raper and of Nobutani are not wholly convincing, since the strengths of the catalase preparations used were not indicated and it was not shown that the catalase remained active throughout the oxidation process. Keilin and Hartree in 1935 had also shown that under certain conditions catalase may promote a secondary oxidation involving the hydrogen peroxide formed during an enzymatic oxidation. When catalase so functions, the decomposition of the hydrogen peroxide does not result in the liberation of molecular oxygen and the return of this to the reaction system, and the formation of hydrogen peroxide would not be detected by oxygen uptake measurements.

Dawson and Ludwig have used tyrosinase preparations having no peroxidase activity and negligible catalase activity in the oxidation of catechol. They made use of the fact recently discovered by Dawson and Nelson that the production of quinone by the enzymatic aerobic oxidation of catechol can be followed by titration with iodine, and when produced under certain conditions, for example, with an optimum amount of enzyme in very dilute solutions of catechol buffered in the *p*H range 4.2–6.6, the stability of the quinone is such that the stoichiometric relationship between it and the catechol can be demonstrated[2]. Since both quinone and hydrogen peroxide liberate iodine from hydriodic acid, the indefinite status of the hydrogen peroxide controversy tended to obscure all interpretations, and Dawson and Ludwig have attempted to clear up this point. Their tyrosinase preparations were obtained from the common mushroom by suitable purification, and the activity was measured by the method proposed by Graubard and Nelson. In dilute solutions buffered within the *p*H range 4.1–6.7, the oxidation product formed in the initial stages of the catechol-tyrosinase reaction was equivalent to two atoms of iodine per molecule of catechol, which corresponds to a benzoquinone. This quinone and hydrogen peroxide were shown to be incompatible in solutions buffered to *p*H values above 4.1. It was also shown that in the *p*H range 4.1–6.7 the course of the catechol-tyrosinase reaction as followed by iodometric titration, was unaltered by large amounts of catalase or peroxidases.

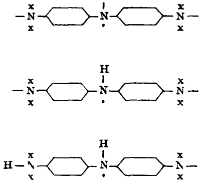
Wagreich and Nelson[3] found that under conditions of low concentration of substrate, high concentration of enzyme, and *p*H 4.5–6.5, catechol is enzymatically oxidized by tyrosinase to *o*-benzoquinone with the consumption of one atom of oxygen only per molecule of catechol, and that the consumption of the second atom of oxygen is also catalysed by tyrosinase. They obtained evidence that a substance is formed when *o*-benzoquinone disappears in aqueous solution at *p*H 4.5–6.5 which is aerobically oxidized to a quinone by tyrosinase, and that the quantity of quinone compound formed in the oxidation of this substance corresponds to one half of the *o*-benzoquinone which has disappeared. It appears, therefore, that the second atom of oxygen used up in the enzymatic oxidation of catechol is concerned with the oxidation of a product resulting from the action of water on *o*-benzoquinone, that hydrogen peroxide is not responsible for any part of the titration values, and that the consumption of two atoms of oxygen per molecule of catechol cannot be attributed directly to the formation of hydrogen peroxide. The question whether or not hydrogen peroxide has an intermediary function during the formation of the initial quinone is still open to debate, but it is considered improbable that such a view of the enzymatic oxidation of catechol can be supported on the present evidence.

Another investigation on oxidation mechanism by a different method is the study of the possible intervention of semiquinone radicals as intermediate steps in oxidation-reduction reactions by G. Schwarzenbach and L. Michaelis[4]. The indophenol dyes had been the object of an extensive and fundamental investigation by W. M. Clark and co-workers, who measured the oxidation-reduction ('redox') potentials by electro-chemical methods. They concluded that there was no evidence for the existence of an intermediate step in the process of reduction but that in reversible bivalent oxidations two electrons always go on and off in pairs. Schwarzenbach and Michaelis now present evidence for the existence of such intermediate steps in the form of semiquinone radicals in the case of phenol blue and Bindschedler's green, two dyes closely related to the group investigated by Clark. Potentiometric redox titrations of these dyes were carried out at various *p*H values and the slope of the titration curves indicates that an intermediate semiquinone radical is formed. The results were checked by spectrophotometric measurements.

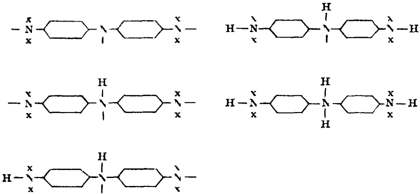
The totally oxidized semiquinone and fully reduced forms are denoted by *T*, *S* and *R*, respectively, an open structure being chosen for the *T* forms in which the central nitrogen appears surrounded by only six electrons. The fourth electron pair can be said to be delivered by the auxochrome groups $N(CH_3)_2$, OH and O, which have unshared electron pairs able to form double bonds with the adjacent carbon atom, so converting the benzene ring containing it into a quinoid ring. Both auxochrome groups can so participate and the molecule is a resonance system. The formulæ above apply to Bindschedler's green, similar formulæ are given in the paper for phenol blue and phenolindophenol. Each stroke represents an electron pair, and in the *S* form the odd electron is provisionally shown by a dot as attached to the central nitrogen atom, although this is not to be regarded as assigning a definite position to it. Methyl groups are denoted by x.



2 T forms



3 S forms



3 *R* forms

Titrations were mostly reductive, with reduced rosindulin *GG* and in a few cases titanous chloride. The air in the titration apparatus was replaced by hydrogen, and colloidal palladium ensured the removal of oxygen and produced a hydrogen potential which made possible the measurement of the *p*H of the buffer. In oxidative titrations the hydrogen was then replaced by nitrogen. Apart from the titration curves, the semiquinone could also be detected by its colour.

All three dyes showed strong semiquinone formation in the alkaline and acid range and comparatively small semiquinone formation in the middle *p*H range. The effect in the alkaline range may be explained as follows. In non-aqueous solutions the formation of *R* and *T* forms from a free radical is generally negligible and only the equilibrium between the dimeric form and the radical occurs. Such solutions, however, correspond with a solution of very high *p*H since the *R* form cannot take up a proton. The sensitivity of the solutions to water follows from the proton donation of the water being equivalent to a strong lowering of *p*H by converting the *R* form into H*R*

$$R + H_2O \rightleftharpoons RH + OH$$
$$2S + H_2O \rightleftharpoons T + RH + OH$$

This is the main reason for the dismutation effect caused by the addition of water to the radicals.

The general treatment of oxidations and reductions of organic compounds must take account of the equilibria

$$\begin{tikzcd} R \arrow[r, leftrightarrow, "e"] & S \arrow[r, leftrightarrow, "e"] \arrow[d, leftrightarrow] & T \\ & \tfrac{1}{2}D & \end{tikzcd}$$

The reaction $D \rightleftharpoons 2S$ in non-aqueous solutions is standard for the preparation of radicals, redox potentials refer to $R \rightleftharpoons T$. The two processes were linked simultaneously by Friedheim and Michaelis[5] and Elema[6] who noticed the formation of free radicals in oxidations and reductions even in aqueous solutions. Michaelis and Fletcher[7] also found the dimeric form (*D*) in equilibrium with the radical. The semiquinones all contain two equal atoms (other than carbon) symmetrically located in the molecule, and these atoms can be regarded as carriers of an odd electron, e, which resonates symmetrically between the two positions, for example, as in Wurster's blue

$$\overset{+}{(CH_3)_2N}\langle \leftarrow e \rightarrow \rangle \overset{+}{N(CH_3)_2}$$

The older free radicals, on the other hand, contained one atom which might be considered as the carrier of the odd electron, so that it was reasonable to speak of tervalent carbon, bivalent nitrogen or univalent oxygen. These radicals were found to be very sensitive to water. The present investigation closes the gap between the two groups of radicals, examples of the second type having been found which exist in aqueous solution in equilibrium with *R* and *T* forms. As Hückel and Pauling have shown, all free radicals owe their existence to resonance energy, the odd electron and the π electrons of the aromatic nuclei not being in a definite position but appearing as a time average of charge distributed over a wide range of the molecule

Schwarzenbach and Michaelis discuss in detail the relative stability of the molecules involved, that is, those given in the above and similar tables, on the basis of qualitative valency considerations An atom in an 'ideal' state is assumed to be surrounded by four equal and indistinguishable electron pairs Reactivity may then arise from (1) a deviation from the stable electron number 8, for example, in the fluorine atom (oxidation-reduction instability), (2) a deviation from the ideal state of equality of the four electron pairs, for example, in the NH_3 molecule giving rise to basic properties (acid base instability) It follows that the *R* forms show primarily acid base instability, which is great in alkaline solution, that the *T*-forms show greater instability (oxidation reduction unstability) in acid solution, the radical *S* is stabilized by a resonance phenomenon differing from the resonance of the *T* form ((*a*) *T* form reson ance between two halves of molecule, (*b*) *S* form resonance of semiquinone type, which can be exhibited in one ring containing two nitrogen or oxygen atoms in symmetrical positions, *o* or *p*, but also in double rings, as in benzidine or γ,γ' dipyridyl)

It is emphasized that practically none of the organic radicals known prior to the discovery of the semiquinones exhibit the peculiar type of strongly symmetrical resonance structure characteristic of the semiquinones Correspondingly, these older radicals are usually not stable enough to be capable of existing to any appreciable extent in the presence of water, in contrast to the semiquinone radicals

In a further paper, L Michaelis, M P Schubert, R K Reber, J A Kuck and S Granick[8] deal with a paraquinone, duroquinone (tetramethylbenzoquinone), which shows stability to alkalis Potentiometric and magnetometric methods agree in showing that in sufficiently alkaline solution a free, strongly para magnetic, semiquinone radical of brown colour is formed as an intermediate step of reversible reduction This radical has no measurable tendency to form a valency saturated dimeric form in the dissolved state

Benzoquinone and hydroquinone form the solid quinhydrone, but no corresponding compound can be formed by ordinary methods from duroquinone The dimeric form is assumed to be formed by hydrogen bonds

$$\left\{\begin{matrix} CO - H - OC \\ CO - H - OC \end{matrix}\right\}$$

involving a resonance between two fictitious structures in which alternately the one and the other half of the molecule (represented by brackets) is in the quinoid or benzenoid state In orthoquinones there is no steric restriction in forming these bonds In paraquinones, the two bonds can be formed only by applying the two rings flat upon one another In duroquinone, however, the voluminous side chains prevent a sufficiently close approach

New Satellites of Jupiter

IN NATURE of September 24, p 564, reference was made to the various orbits that had been computed for Satellite x by Dr Paul Herget and Dr M Davidson Dr Herget obtained two orbits with high eccentricities, exceeding 0 6, but the orbits differed essentially, one being direct and the other retrograde As the latter gave smaller residuals, it was adopted, and it appeared that the least and greatest distances from Jupiter were 6 million and 30 million miles, respectively As this last distance is probably outside the stable region for a satellite, it was obvious that further investigation was necessary before any definite pronouncement could be made

Dr Davidson's orbit was quite different from those of Dr Herget. He found that the motion was direct, almost circular, and that the distance from Jupiter was about 7 million miles, but expressed some doubt whether it was just inside the orbit of Jupiter vi or outside that of vii

Further observations have been made, and from these Dr. R H Wilson has computed a new orbit (Harv. Card 460) It now appears that the very eccentric orbit was in error and that the satellite has a small eccentricity, 0 14051, its mean distance from Jupiter being just over 7 million miles, as previously given by Dr. Davidson Its inclination is 28° 24′ and its period of revolution 254 days The satellite belongs to the same group as Satellites vi and vii, and it may be conjectured that there is a family of small satellites in this region, most of them too small to be detected Even the existence of three is a puzzle How did they originate? They are very far outside the Roche limit, and so cannot have been disrupted by Jupiter

Dr P Herget has also computed an orbit for Satellite xi It is moving in a retrograde orbit at an inclination to the plane of the ecliptic of 16 6° and a mean distance of 14 million miles from Jupiter Its eccentricity is 0 207 and its period 692 5 days The elements of the orbit will probably be improved later when more observations are available

In a letter to NATURE of October 8, p 670, Mr J Miller suggested that the retrograde satellites followed an arithmetical progression law, not a geometrical progression law to which the direct satellites conformed approximately, and suggested that Satellite xi would be about 16 million miles from its primary Actually the satellite does not obey either rule, but it is much closer to the arithmetical progression law than to the other It is very remarkable that there are three satellites with direct motion, vi, vii, and x, at a distance of about 7 million miles, and three with retrograde motion, viii, ix, and xi, at distances between 14 and 15 million miles Cosmogonists will find something here on which they can speculate

Science News a Century Ago

The Trogon

Dr Daubeny who had recently returned from a visit to America and the West Indies, on November 12, 1838, at a meeting of the Ashmolean Society, Oxford described some of the zoological specimens including about sixty birds which he had brought back and intended for the Ashmolean Museum Among the birds was a very rare trogon, from the island of Cuba Mr Holme, of Christ Church College, observed that the specific name of the trogon was *Temnurus*, from the ends of the tail feathers appearing as if cut and spread out The only other specimen in Europe was in the Museum at Paris and had been figured in Temminck s Planches Coloriées There was also an uncoloured figure, from a drawing by Colonel Hamilton Smith, in the seventh volume of Griffith s Animal Kingdom

Asiatic Society

At a meeting of the Asiatic Society on November 17, 1838, two of the communications read were from Dr Falconer superintendent of the Honorable East India Company s Botanical Garden at Saharanpore, in lat 30° N The first referred to the cultivation of plants in the garden likely to become important articles of commerce The tea plant was thriving in the nurseries in the neighbouring hills the Otaheite sugar cane had been a success, the Egyptian cotton seemed likely to thrive while among other plants mentioned were the Ceylon cinnamon American annotto, Bombay mangoes and the Chinese litchee (*sic*) Dr Falconer s other letter was written from Cashmere

Another paper read was On the Yellow Colour of the Barberry , in which Mr E Solly stated that the root of the common barberry or *Berberis vulgaris* was used for dyeing leather yellow, and that from experiments made by him in the Society s museum he was convinced that the root would prove an article of considerable value to dyers

F J V Broussais (1772-1838)

November 17 marks the centenary of the death of François Joseph Victor Broussais, the founder of the so called physiological medicine and one of the most eminent physicians of his time He was born at St Malo on December 17 1772 qualified in Paris in 1803 took part in the Napoleonic campaigns in Holland, Germany and Spain, became physician in chief to the Val de Grâce Military Hospital in Paris, and was the author of several works of which the principal are the following Histoire des phlegmasies ou inflammations chroniques (1822), Examen de la doctrine généralement adoptée ' (1816) and "De l'irritation et de la folie (2nd edition, 1839) The main features of his doctrine were the denial of specificity, the attribution of all diseases to gastro enteritis and the reduction of therapeutics to the application of leeches and a restricted diet His teaching, which for many years had an enormous vogue, was finally overthrown by P C A Louis

M Gaudin's Lime Light

On October 19, 1838, M Gaudin had shown some experiments to the Paris Academy of Sciences on his new method of illumination On November 17 the *Mechanics Magazine*, under the heading "Substitute for the Sun , said The newly invented light of M Gaudin on which experiments were recently made in Paris, is an improved modification of the well known invention of Lieutenant Drummond While Drummond pours a stream of oxygen, through spirits of wine upon unslaked lime, Gaudin makes use of a more ethereal kind of oxygen which he conducts through burning essence of turpentine The Drummond light is fifteen hundred times stronger than that of burning gas , the Gaudin light is, we are assured by the inventor, as strong as that of the sun or thirty thousand times stronger than gas M Gaudin proposes to erect on the island of the Pont Neuf in the centre of Paris, a lighthouse five hundred feet high, in which is to be placed a light from a hundred thousand to a million pipes strong, the power to be varied as the nights are light or dark Paris will thus enjoy a sort of perpetual day , and as soon as the sun of the heavens has set the sun of the Pont Neuf will arise

Horticultural Society

In its column of Weekly Gossip , the *Athenæum* of November 17 1838 said We understand that in consequence of the disturbed state of Mexico, and the difficulty of obtaining any package from that country, because of the rigour with which the French squadron maintains the blockade of Vera Cruz and Tampico, the Council of the Horticultural Society have decided upon withdrawing their collector, Mr Hartweg and sending him to investigate the botany of the State of Guatemala The mountainous region, which cuts this magnificent country into two parts and which abounds with most noble vegetation to an elevation of more than 13 000 feet above the sea cannot fail to afford Mr Hartweg a rich harvest

The State and Medical Research

IN the Harveian Oration delivered by Sir Edward Mellanby before the Royal College of Physicians on October 18 and summarized in NATURE of October 29 certain points were raised of such importance particularly at the present time that it seems desirable to underline and amplify them

A realization of the urgent need for medical research makes no call on the imagination and demands no special medical knowledge We have all seen pain disease and death at close enough quarters to wish that we were better armed against them and it is evident that the only effective arms we can hope for are those fashioned for us by science

What is not so fully realized at least by the general public is that the case for extended research is stronger than ever before because the prospects are brighter As always in the growth of science each new discovery brings other discoveries a little nearer so that the potential rate of advance continuously increases It would not have been easy fifty years ago to indicate how large sums of money could best be spent to hasten our acquirement of the knowledge that alone will enable us to control disease It is certainly true to day that our rate of advance is mainly determined by finance We can spend to advantage more than there is any likelihood of our obtaining and the date at which mankind will be freed from the dread of such killing or disabling diseases as cancer tuberculosis and rheumatism depends in the main on how much we are prepared to pay This does not mean that a frontal attack is necessarily the best or the speediest method of gaining the knowledge that we require The sure road to success is to stimulate the growth and development of the medical sciences as a whole Lister followed Pasteur aseptic surgery was the outcome of studies on fermentation We cannot tell where we shall find the key to any of the more obstinate puzzle locks of medicine

It is only by adequate and wise endowment that such a growth of the medical sciences can be secured The return such endowment would give us may reasonably be assessed in the light of our gains in the past To take only recent advances diabetes and pernicious anæmia incurable and fatal diseases not many years ago are now readily controllable We can if we choose eliminate diphtheria as an important infection of childhood We are at last in sight of an effective attack on influenza one of the major killing diseases of adult life The discovery of the therapeutic action of sulphanilamide and its related compounds has not only given us our first effective weapon against puerperal septicæmia the main cause of maternal mortality but also has brought bacterial infections in general into the field of chemotherapy which hitherto seemed to be limited to protozoal diseases

The funds required to maintain a healthy activity throughout the whole research field involved and to concentrate additional resources at any point which promises a rapid advance are large—large at least in terms of the inadequate resources that have been available in the past, though trivial in comparison with the sums expended on health administration that is often ineffective because it lacks the necessary knowledge on which to act Some part of the money required may be provided by the munificence of private donors or by public subscription Sir Edward

Mellanby instanced some of the funds available for this purpose, such as those administered by the Leverhulme Trustees, the Halley Stewart Trustees, and the British Empire Cancer Campaign. There is an expectation of additional support from the Wellcome Trustees, and British medical research already owes much to the generosity of the Rockefeller Foundation of America—a generosity which, as Sir Edward emphasized, might well prick the conscience of some of our own countrymen. It is reasonable to expect more help from industry in the future than we have received in the past, particularly in the rapidly expanding field of chemotherapy, and it is perhaps not too much to hope that our large life insurance companies, which benefit directly from the increased expectation of life consequent on the increase of medical knowledge, may one day be stimulated by the admirable example set by similar bodies in the United States. But, whatever help is available from such sources as these, it is inevitable that the greater part of the burden should be carried by the State, for the State bears the ultimate responsibility for national health and for financing the measures that are necessary to secure it. It is in relation to the form in which State endowment can best be supplied and utilized that Sir Edward Mellanby's account of the working of the Medical Research Council is of particular interest.

Bureaucracy, giving the term its common and well justified implication, is the inveterate enemy of research. State endowment means State control, and if 'State' and 'bureaucratic' were synonymous terms the outlook would be dark. But the Medical Research Council, under the wise guidance of its two secretaries, the late Sir Walter Fletcher and now Sir Edward Mellanby, has shown that bureaucracy is a malignant growth that a Government department can quite easily prevent by a simple willingness to delegate, not final authority, but provisional decisions, and the carrying out of plans that have been approved. Incidentally, the Council has also shown that bureaucracy is as expensive as it is obstructive, and that its elimination leads to a great saving of public funds. Working through a large number of unpaid expert committees, the Council has encouraged those who know how research can best be stimulated and assessed to do these things for nothing. As a result, the Council's administrative expenses are a very small fraction of the total funds at its disposal, and the greater part of its financial resources are expended on the salaries of research workers, or on the laboratory expenses associated with their work.

Moreover, by enlisting the voluntary help of a large number of senior workers in universities, research institutes and hospitals, the Council has been able to co-ordinate investigations in a way which no other body could approach, and to ensure, so far as is humanly possible, that economy is safeguarded by terminating lines of research that have served their purpose or have failed to fulfil their promise, and by concentrating the available resources in the most promising fields. Its ability to do this, it should be noted, is largely due to the fact that it acts on the advice of those who know what is actually happening, and, as a result, has won their trust and willing co-operation. It does not seem impossible that a method which has proved so successful in one branch of Government activity might be equally effective in others. We are an empirical people, and learn more readily from experience than from argument.

One other point that was stressed by Sir Edward Mellanby deserves further amplification—the unnecessary lag that is apt to occur between the discovery of a method that is applicable to the diagnosis, cure or prevention of human disease and its adequate practical exploitation. This lag is far less conspicuous on the curative than on the preventive side. A new therapeutic agent tends to be tried out at once, and on a wide scale. The trouble is that the trial is often uncritical and uncontrolled, and that the factors that determine the use, or abuse, of the new remedy take longer than they need to win general recognition. The Medical Research Council has made a start towards removing this defect by setting up a Therapeutic Trials Committee.

It is on the preventive side, and particularly in relation to the application of new methods of preventing infective disease, that the lag is longest, and the position in Great Britain is most discreditable, perhaps because this field of activity, on its applied side, has not hitherto been regarded as falling within the Council's sphere. It is not flattering to our sense, humanity or self-respect that we have no central or regional institutes of hygiene, or State laboratories, comparable to those that have been established in the great majority of other civilized countries. The United States, in addition to the National Institute of Health at Washington, has numerous State institutes such as the Division of Laboratories and Research of the New York State Department of Health. Germany has the Reichsgesundheitsamte in Berlin Denmark the State Serum Institute in Copenhagen Italy the Institute of Public Health in Rome Poland the Institute of Hygiene at Warsaw Hungary the Institute of Hygiene at Budapest Turkey at Ankara Czechoslovakia at Prague Rumania at Bucharest Jassy and Cluz Yugoslavia at Belgrade and Zagreb and so on

All these institutes though varying in their detailed functions and in their exact relation to the State serve as national or provincial centres which stimulate the scientific attack on infective disease aid in the practical application of new discoveries to preventive problems and provide for public health administrators facilities that they could obtain in no other way

Other parts of the British Commonwealth are in this matter well ahead of Great Britain as is shown for example by the admirable work carried out by the Connaught Laboratories in Toronto Our neglect of this obvious deficiency is humiliating and not without its dangers to health even in ordinary times In times of emergency it may unless remedied entail improvisations that with all their attendant difficulties and disadvantages would be unnecessary if our peace time organization were less defective

In many ways the practice of medicine in Great Britain is as good as anywhere in the world British public health legislation and practice have a proud history since the days of Chadwick and Simon Our universities and our institutes of medical research have made outstanding contributions to knowledge and are fully capable of adding to them Our future position in the world of medical science which in addition to its national importance plays no small part in international relationships and co operation will depend mainly on the willingness of the Government to provide the necessary funds and on the extension to wider fields of the wise methods by which the Medical Research Council has encouraged integration while allowing freedom and initiative within the territory it has covered in the past In particular there must be a clearer recognition of the interdependence of research and practice A problem in the prevention or cure of disease has not been solved until a finding reached in the laboratory has been tested and applied in the ward or in the field and has been exploited to the limits of its usefulness The method of approach that will succeed in the earlier stages will succeed in the later and other methods will fail The bureaucratic method is is incapable of applying discoveries effectively as it is of making them State endowment and encouragement of those who alone can do the work required will yield the results we need and yield them at the minimum cost

---

Modern Methods in School Science

A Modern Introduction to Science

By Dr W P D Wightman and A O Chesters Part 1 Pp vii+158+4 plates 2s 3d Part 2 Pp vii+170+4 plates 2s 6d Part 3 Pp vii+248+4 plates 3s 6d Part 4 Pp viii+275+6 plates 3s 9d (Edinburgh and London Oliver and Boyd 1936–1938)

THERE is something arresting in the title which Dr Wightman and Mr Chesters of the Edinburgh Academy have given to this series of books An Introduction to Modern Science might mean many things but A Modern Introduction to Science suggests that the authors have a new method of approach and so in fact they have They have shared the dissatisfaction of many teachers with the traditional ways of teaching elementary science, and their main aim is to guide a young reader towards reasoned answers to questions to which his own curiosity naturally leads him Accordingly each topic is presented as a problem to be attacked in a spirit of discovery and not as a verification of something already known In elucidating problems the authors often follow historical lines and usually they have done so with admirable discretion In general it may be said that they present science as a matter of personal concern to the young students who are enabled to pluck the fruits of knowledge from all the main branches of the subject

The first two parts of the series were already printed before the Science Masters Association made its interim report (1936) on The Teaching of General Science In their preface to the last two parts of their work the authors comment upon the close agreement between the findings in the report and the principles which they had quite independently come to regard as basic The similarity is indeed quite remarkable for the work reads almost as if it had been written with the report as its basis

The agreement is even closer than the authors themselves realize for their method of presentation which they call the unitary approach is in complete accord with the findings in the report The authors are mistaken in thinking—to quote from their preface—that the Committee were of the opinion that the tripartite division of science was so natural and convenient that to depart from it savoured of artificiality What the Committee said on this point—and it was stated in italics—was that general science should seek to elucidate the general principles observable in nature without emphasising the traditional division into specialised subjects until such time as this is warranted by the increasing complexity of the field of investigation by the developing unity of the separate parts of that field and by the intellectual progress of the pupils That again seems to be exactly as the authors think desirable for as they state in their preface they cast Part IV of their book in sections corresponding roughly to the principal branches of science The agreement in principles between the authors and the Committee seems to be complete and as might therefore be expected there is close similarity in the choice of teaching material as well as in the method of presenting it

One can imagine a classically trained sixth form boy who wished to know what science was about simply revelling in this work but there are a few points which cause misgivings about its application to the small boys for whom the earlier parts of the book are designed The style of the English in the first part of the book since it is no simpler than that in the last seems too hard for the younger boys The chemical balance is introduced too soon The general treatment is too logical for the beginners who are at an age when they hunger for facts and experience and soon tire of trying to follow a long train of reasoning It might have been wiser to sacrifice some of the logical connexions in order to crowd the first part with things which are easily comprehended by young minds In Part II which one may suppose will be studied by boys of thirteen or fourteen years of age the historical method of approach to electrical ideas seems to be laboured and one wonders (page 121) how many boys will remember the shapes of graphs of the type $y=x^2$ These however are debatable points which have been mentioned didactically for the sake of brevity They should not be allowed to detract from a favourable opinion of a series which marks a notable advance in methods of teaching science to beginners

C I Bryant

The Theory of Allotropy

Die Theorie der Komplexität und der Allotropie
Von Prof Dr A Smits Pp xii + 372 + 5 plates (Berlin Verlag Chemie 1938) 19 50 gold marks

THE views held by Prof Smits as to the complexity of phases which are usually considered to be simple were set out in his Theory of Allotropy published in 1922 Since then many new results have been obtained and the present volume lays special emphasis on the new experimental data and their interpretation from the point of view of the theory

The book opens with a chapter describing the experimental evidence for pseudo components from vapour pressure and melting point anomalies The fundamental hypothesis is then defined ' all phases including the gaseous and solid phases of a so called simple substance are composed of different kinds of molecules which are inter convertible The remainder of the volume consists of a full theoretical discussion of the consequences of this hypothesis when the rate of interconversion is slow together with a detailed description of experimental studies of systems in which the rate of interconversion is slowed down by intensive drying or by low temperatures

One of the most interesting points which arises from the theory concerns the physical or chemical nature of the different kinds of molecules which form the pseudo components A brief discussion in one chapter suggests that apart from chemical isomerism in more complex molecules one may have to consider differences of nuclear spin as with ortho and para hydrogen or rotational energy differences as in crystals of ammonium chloride In the limit it may even be necessary in a gaseous phase to regard each group of molecules with a given rotational energy quantum as a pseudo component ! For systems of the type of SO_2 and intensively dried benzene the data are interpreted as indicating interconversion between polymers and simpler molecules

Both theory and experiment are described with admirable clarity and the book is enriched by a large number of well chosen diagrams S S

Modern Organic Chemistry

Organic Chemistry:
an Advanced Treatise Editorial Board Henry Gilman, Roger Adams, Homer Adkins, Hans T Clarke, Carl S Marvel, Frank C Whitmore Contributors (other than Members of the Board) C F H Allen, W E Bachmann, A H Blatt M T Bogert, W R Brode, L F Fieser R C Fuson, E Heuser, C D Hurd, J R Johnson T B Johnson, J A Leermakers, P A Levene, K P Link L Pauling, A L Raymond, A Rothen R L Shriner, L Small W H Strain, E S Wallis, M L Wolfrom Vol 1 Pp lvi+857 Vol 2 Pp lvi+858–1890 (New York John Wiley and Sons, Inc , London Chapman and Hall Ltd , 1938) 37*s* 6*d* net each volume

THE very rapid growth of organic chemistry alike on the descriptive side and in the theoretical aspects of the subject, has produced acute problems for teachers of chemistry particularly for those concerned with final honours or post-graduate students Whilst numerous and excellent elementary and intermediate text books are available for use in the early stages of the curriculum, comprehensive advanced treatises are few in number

The volumes under notice, planned by an editorial board of American chemists and written by American chemists, go far towards filling the gap, and their publication is to be regarded as an outstanding event in the bibliography of organic chemistry The variety and extent of the subjects to be considered render it inevitable that a treatise of this type must be a joint effort, and the two volumes under review consist in effect of a series of monographs written by acknowledged authorities on these special subjects The names of the members of the editorial board and of the contributors, given above, are sufficient indication of the high quality of achievement to be expected in the various chapters, and their success in providing readable, authoritative, and well-balanced accounts of the various subjects is amply confirmed by a study of the work Each of the chapters is a fully documented monograph, complete in itself but carefully related to the general scheme of the work, giving a review of the subject as it stands at the present day, with many references to new work published so recently as 1937 It is a welcome feature that by adopting the method of separate sections, the editorial board looks forward to flexibility in bringing new editions up to date and including in them chapters on subjects omitted from the present volumes

In a short review no attempt can be made to refer in detail to each of the twenty two separate monographs but some idea of the wealth of subject matter may be derived from a brief consideration of the subjects selected for discussion A masterly survey of the theory of the structure and reactions of aromatic compounds by L F Fieser occupies some 100 pages whilst the related subjects of modern electronic concepts of valency and the significance of resonance to the nature of the chemical bonds are dealt with in important chapters by J R Johnson and L Pauling respectively Carbohydrates are included in three sections the first by M L Wolfrom, who deals with the general problems of stereochemistry, ring structure etc , and the chemistry of the simple sugars and oligosaccharides A L Raymond writes on substituted and derived sugars including vitamin C, and on the isomerization and degradation of sugars, including fermentation In the third section E Heuser provides a comprehensive account of the chemistry of cellulose The long article (256 pages) on stereoisomerism by R L Shriner, Roger Adams and C S Marvel amounts practically to a complete and much needed text book on this branch of organic chemistry, and there are further chapters by P A Levene and A Rothen on optical rotatory dispersion one of the newer and potentially very valuable methods of investigating organic substances, and on the theory of strain by R C Fuson Amongst the groups of natural products included are amino acids (H T Clarke), pyrimidines, etc (Treat B Johnson) alkaloids (L Small) anthocyanins and flavones (K P Link), carotenoids (M T Bogert) and sterols bile acids and related compounds (W H Strain) There are sections on organometallic compounds (H Gilman), free radicals (W E Bachmann), unsaturation and conjugation (C F H Allen and A H Blatt), open chain nitrogen compounds (C D Hurd) and other aspects of organic chemistry are considered in sections on molecular rearrangements (E S Wallis), comparison of chemical reactivity (H Adkins) and on constitution and physical properties (W R Brode and J A Leermakers)

When so much is given, and given in a manner which it is difficult to praise too highly, it would appear invidious to wish for more It seems unfortunate, nevertheless, that the really excellent sections on the carbohydrates, which include cellulose, should contain no account of starch, glycogen, hemicelluloses, polyuronides or other related polysaccharides Furthermore, the account of the nucleic acids is scarcely adequate in its references to modern work It is inevitable, however, that a work of this kind should be incomplete as regards subjects selected for discussion and in the preface the editor in chief promises additional chapters on polymerization and on chlorophyll for inclusion in the next edition When it is found that the present edition runs to nearly 2,000 pages, some idea is gained of the scope of modern organic chemistry The work is well produced, and the clear type and the excellence of the numerous formulæ and diagrams deserve special mention These are quite certainly volumes the merits and importance of which render them indispensable to all serious students of organic chemistry

Research near the Absolute Zero

Low Temperature Physics
By M and B Ruhemann Pp ix + 313 (Cambridge At the University Press 1937) 18*s* net

APART from the determination of the characteristics of the liquefied gases used to produce low temperatures, the original aim of low temperature research was to investigate the fundamental properties of matter in the absence of the disturbing effects produced by thermal agitation Although this aim has been to a large extent achieved, its attainment has been complicated and research made more exciting by new phenomena which have appeared in this temperature region and by previously known phenomena which have become relatively more important Incidentally the rapid advance of this branch of physics is illustrated by the fact that most physicists would now confine the term 'low temperature' to the region within a few degrees of the absolute zero

The book under review is written by experienced workers, and gives a very readable account of the whole range of low temperature research, "mainly for physicists specializing in *other fields*" It commences with a history of gas liquefaction, followed by an account of the commercial liquefaction of air, and its rectification an account full enough to include calculation of efficiencies of liquefaction processes and the methods of 'rectification calculus (It is interesting to read in this connexion that Keesom has shown that the old Pictet process can be more efficient than either the Claude or the Linde) This is followed by chapters on the laboratory methods of making hydrogen and helium and on their use in the production of the low temperatures with which the book is mainly concerned It is entirely owing to the recent improvements in the small scale production of liquid helium that we owe the fruitful extension of its use to laboratories not originally equipped for work in this field The non continuous expansion method is even more adaptable than the reader would gather from the account here as instead of the duration of the experiment being limited to "an hour or more experiments lasting more than twelve hours are often carried out after a single expansion

For work below about 1° K we have to rely on other methods So long as a property is changing with temperature we can make use of this property (at any rate in principle) to attain yet lower temperatures How the magnetic susceptibility of certain paramagnetic substances has been used for this purpose is described in a late chapter, in which is also included a clear description of the method of determining the temperatures reached on the absolute thermodynamic scale particularly interesting as perhaps the only case in which its definition is directly applied The inaccessibility, in the light of Nernst's Third Law, of the absolute zero is discussed in a useful chapter on that law The importance of low temperature measurements to processes in chemical industry is also stressed in this connexion

The remainder of the book consists of a summary of the results of research in its principal branches, including chapters on liquid solid equilibrium, thermal and other properties of the solid state, magnetic phenomena, and the remarkable properties of superconductors Although there are excellent accounts of these last elsewhere it seems a pity, in view of the appeal of this book to non specialists, that the section here is not fuller It is also to be regretted that there is no account of work subsequent to 1935, although a bibliography up to May 1937 is appended But in spite of these defects and of a very few minor misprints the authors are to be congratulated on the very successful fulfilment of their aims T C K

The Revival of Agriculture

a Constructive Policy for Britain Prepared by a Committee of the Rural Reconstruction Association Pp 138 (London George Allen and Unwin Ltd 1936) 3s 6d net

THIS book presents a policy for agricultural reconstruction with a strong bias towards economic nationalism which the authors like Signor Mussolini, prefer to call realism It gives a clear exposition of the case for national self sufficiency based on planned agricultural organization but tends to minimize the disadvantages that might accompany self sufficiency Not everyone will agree with the following sweeping statement (p 125) It is not arguable that the mere moving of goods backwards and forwards across the seas though it gives employment to both men and capital, has in itself an economic value One wonders whether the mere moving of apples from the orchard to the market and thence to the consumer could be dispensed with as easily as shipping or whether the interposition of water makes all the difference to the necessity for distribution

The main idea is that our national survival depends on getting more people back to productive work on the land and keeping them there in comfort and security Few will contend the desirability of this object The authors realize that it would involve very careful organization of both production and distribution and full protection of the rural community against price fluctuations slumps etc Much of the security however is to be purchased at the cost of the financial and commercial interests that in the past have certainly feathered their nests more effectively than has agriculture which the authors rightly regard as the foundations of our civilization It is the misfortune of foundations that they have no place in the sun What the ultimate consequences to the whole structure of civilization would be of turning the foundations into pinnacles is a question which nobody can yet answer G V J

Coordinate Solid Geometry

Being Chapters I-IX of An Elementary Treatise on Coordinate Geometry of Three Dimensions By Prof Robert J T Bell Pp xiii+175+xliii (London Macmillan and Co, Ltd 1938) 7s 6d

THIS book contains as its text, the first nine chapters of Prof Bell s well known Treatise on Coordinate Geometry of Three Dimensions It therefore leads up to and completes the treatment of the central surfaces in order to meet the needs of those students who do not desire to study mathematics beyond a pass or general degree standard

The author has made an interesting and appropriate selection of miscellaneous examples from his larger work and in addition has provided an entirely new set An appendix has also been added in which alternative and simplified methods to several parts of the original text are given

The book bears all the excellent features of the "Treatise" and should be of great use to the students for whom it has been prepared

Silicate Analysis

a Manual for Geologists and Chemists, with Chapters on Check Calculations and Geochemical Data By Dr A W Groves Pp xxi+230 (London Thomas Murby and Co 1937) 12s 6d net

THE chemical analysis of silicates is of importance not only in the pure sciences of geology, mineralogy and geochemistry but also in many branches of technology and industry The standard works in English on this subject are those of Hillebrand and Washington and the methods of analysis described in this volume include many given by these workers These standard methods, however have been modified where the author s experience has shown such modification to be necessary and further, other methods are given in detail Great attention is paid to minutiæ of manipulation and for ease of consultation the instructions concerning the procedure of the analysis are printed in large type

After introductory chapters on the equipment of the laboratory reagents sampling and routine operations the main part of this volume deals fully with the normal methods of silicate analysis The concluding chapters are devoted to such topics as special methods analyses for industrial purposes errors in silicate analysis and the geochemical distribution of the elements

This book, which is well produced provides a detailed guide in silicate analysis for both chemist and geologist

Modern Optical Projectors

a Practical Handbook on the Principles and Construction of Optical Projection Appliances for the Lecture Room Laboratory and Workshop By Edgar T Westbury Pp 124 (London Percival Marshall and Co Ltd n d) 3s 6d

THERE is a decided place for this little book in lecture room laboratory or workshop As years have gone on it is surprising what developments have taken place since the magic lantern provided the only means of illustrating a lecture Yet it remains the prototype of all the more or less elaborate instruments which are in common use to day for such a purpose

The information given by the author is severely practical and covers the whole range of problems likely to arise in the construction and care of projectors Two points are worthy of special mention One is the need for absolute darkness during the exhibition of slides It appears that some five candle power of stray light on the screen is enough to spoil the effect of five hundred candle power of illumination from the lantern This is common experience, but it is interesting to have figures The other matter is the value of optical projection in the workshop, for example, in the testing of screw threads by casting a shadow of the screw upon the screen at the same time as an enlarged working drawing Imperfections are readily revealed by this method The book is well produced and liberally illustrated

Die mikroskopischen Boden-Pilze

ihr Leben ihre Verbreitung sowie ihre öconomische und pathogene Bedeutung Von Dr Anneliese Niethammer Pp vi + 193 + 6 plates ('s Gravenhage Dr W Junk, 1937) 13 florins

It is always a gratifying stage in the development of any department of science, when a large number of detailed investigations can be collected correlated, and woven into a coherent philosophy of the subject as a whole That stage has arrived in the study of soil mycology and the monograph under review is worthy of the occasion Literature upon the taxonomy of microscopic fungi which live in the soil has been comparatively unavailable Dr Niethammer's work collects it and the mycologist whose studies have not hitherto been specifically related to pedology may now find his way with relative ease amongst the Phycomycetes Ascomycetes and Fungi Imperfecti which provide the microscopic fungus flora of the soil

The second part of the monograph reviews the distribution of these organisms in relation to world wide geographical and climatic conditions to soil types and to the higher plants which grow thereon This leads to a discussion of the life histories of fungi under natural conditions, their pathology and chemical action upon various substances in the soil Modern conceptions of growth regulating substances are reviewed mycologically, whilst the relation of soil fungi to the practice of manuring is also discussed Many new correlations are here possible, and a large amount of such information is included in the 73 quarto pages of detailed stocktaking which follow the 100 pages of taxonomy The shortening of some generic names to their initial is sometimes disconcerting, whilst the further criticism of the paucity of plates and drawings is only emphasized by the high quality of the six which are included J G

The Conservation of Prints, Drawings and Manuscripts

By Dr H J Plenderleith (Published for the Museums Association) Pp vii + 66 + 5 plates (London Oxford University Press, 1937) 3s 6d net

This is the second member of a series of booklets issued by the Museums Association with the general idea of helping curators in their task of conservation of precious objects It may be said at once that this purpose is admirably fulfilled by the pages now before us

The scheme is, first to consider the nature of the materials in question—paper, parchment, inks and so forth—and then to discuss methods for cleaning and repair Both physical and chemical processes are involved in this work The crux of the whole matter is experience Given that experience, a very modest equipment will enable it to be utilized to the full The value of this manual is that it is the product of profound experience, presented in such a way that others may benefit from it, even if their resources are more limited than those at the author's disposal A number of good illustrations are included

F I G R

Electricity and Magnetism

an Introduction to the Mathematical Theory By A S Ramsey Pp xi + 267 (Cambridge At the University Press, 1937) 10s 6d

Vieille école, bonne école hey? said Major Pendennis and the remark is irresistibly suggested by the contents and scope of a work which covers the schedule for Part I of the Tripos untouched and undismayed by the drums and tramplings of one knows not how many conquests Here the student will find an old story admirably retold and he who would learn to deal effectively with such problems as demand a good working knowledge of Laplace's equation the method of images distribution in networks of conductors self and mutual inductance and the like will find the president of Magdalene's volume an efficient and trustworthy guide He will have much more to learn before he arrives at the confines of modern knowledge of electricity but he will have nothing to unlearn, and a careful study of the book will provide him with knowledge likely to be of great help in his later studies A F

Brompton Hospital Reports

a Collection of Papers recently published from the Hospital Vol 6 Pp iv + 183 + 6 plates (London Research Department, Brompton Hospital 1937) 2s 6d

In addition to three hitherto unpublished articles dealing respectively with multiple cystic disease of the lungs by Drs F H Young and N C Oswald an investigation of the relation of bronchography to post lobectomy atelectasis by Mr R H R Belsey and an investigation on statistical lines of the clinical aspects of senile phthisis by Drs W D W Brooks and F P Lee Lander this volume contains papers which have been published elsewhere on perspective and poise in practice, and various aspects of pulmonary tuberculosis and other diseases of the chest The index of authors for the first six volumes and the subject index for the first five are included The annual report of the Hospital for 1937 is appended

German for Students of Medicine and Science

with Notes, Grammatical Introduction and Vocabulary By W F Mainland Pp xlvii + 160 (Edinburgh and London Oliver and Boyd, n d) 8s 6d net

This useful work is intended to relieve the irksomeness of learning German for the already overworked undergraduate, medical practitioner or lecturer in a medical school, who should welcome the unconventional method adopted The book contains an indispensable minimum of grammar, a short list of German medical journals and a selection of passages from medical and lay writers, classified as easy moderately difficult and advanced, and dealing with anatomy, histology, physiology, biochemistry, pathology and bacteriology, medicine, pharmacology, surgery, hygiene and dietetics, psychology and the history of medicine A vocabulary is provided

Further Evidence on the Structure of the South African Pleistocene Anthropoids

By Dr R Broom, F R S , Transvaal Museum, Pretoria

NO apology need be given for publishing to the world at the earliest possible moment all new evidence that is discovered which seems to throw additional light on the structure of the apes that apparently are related to the ancestors of man Every month reveals some new facts of importance and it seems to me better that these should be announced at once than that they should be held back for perhaps years in the hope of publishing a detailed account

Some weeks after the Kromdraai skull was discovered (see NATURE Aug 27 p 377) I was fortunate in finding in the same matrix as the skull and within a few feet of the spot where it was found three bones of the post cranial skeleton These are the lower end of the right humerus part of the proximal end of the right ulna and a toe phalanx

As will be seen from Fig 1 the humerus resembles so closely that of man that some will doubtless be inclined to refer it to a species of man and to consider the possibility of man having been associated with *Paranthropus* and of course it is impossible to prove that the humerus belongs to the ape Still as in the caves at Sterkfontein and Kromdraai between 3 000 and 4 000 specimens have been collected and no tooth or bone of man has so far been discovered and as this humerus was got close to the skull of *Paranthropus* which in a number of points of structure is nearly man I think it practically certain that the humerus not only belongs to *Paranthropus* but also to the type individual Assuming that it is the humerus of *Paranthropus* it is interesting to note that it is nearly human in all its characters and that it differs markedly from the humeri of the chimpanzee and gorilla From which we may infer as probable that *Paranthropus* like man was a bipedal animal and that the arms were not used for locomotion but for the manipulation of sticks and possibly tools

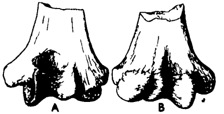

Fig 1
DISTAL END OF RIGHT HUMERUS OF *Paranthropus robustus* BROOM *A* POSTERIOR VIEW *B* ANTERIOR VIEW HALF NATURAL SIZE

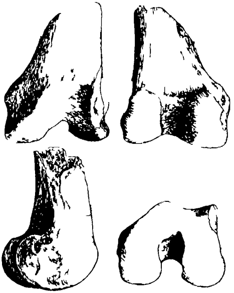

Fig 2 FOUR VIEWS OF DISTAL END OF LEFT FEMUR BELIEVED TO BE THAT OF *Plesianthropus transvaalensis* BROOM HALF NATURAL SIZE

Near the same spot was found part of the proximal end of the right ulna It is not sufficiently well preserved to afford much evidence It is nearly human

The third bone which I believe to belong to the *Paranthropus* skeleton though very small is of great importance It was also got at the same spot and within a few feet of the site of the skull It is the distal phalanx of one of the toes probably of the second (Fig 4*C*) It is too short to be the ungual phalanx of one of the fingers and it seems too long to be the ungual phalanx of a human toe It seems to show that *Paranthropus* had toes like those of man but rather longer

At Sterkfontein the distal end of a femur has been discovered which may be referred with very little hesitation to *Plesianthropus transvaalensis* A little part of the external tuberosity is lost but otherwise the fragment is perfect The accompanying drawings (Fig 2) show that it is nearly human in all its characters The intercondylar notch is relatively narrow, but not narrower than in a Bushman femur I have The femoral fragment seems to indicate that *Plesianthropus* was also probably a bipedal animal.

The intercranial cast of the type of *Plesianthropus* shows that the cranial capacity is about 440 c c As the type skull is almost certainly that of a young female, it seemed probable that the male would have a larger cranial capacity About six months ago, I was fortunate in finding a considerable part of the cranial cast of what I believe to be a male skull Not far from the spot where the cranial cast was found, I obtained part of the skull of an old male Most of the skull was so broken and crushed as to be of little value, but much of the left maxilla and malar are fairly well preserved. All the teeth except the last molar are worn down almost to the roots, and even the last molar is much worn. It seems probable that this upper jaw belongs to the same individual as the cranial cast and that the animal was an old male Though only about half of the cranial cast is preserved, it is possible to make a satisfactory restoration, and it is seen to be very considerably larger than that of the type I give figures on the same scale of the two cranial casts I estimate the capacity of the supposed male skull to be about 600 c c., but as less than half the cast is preserved and it is in part a little crushed, it is impossible to do more than make a rough estimate The capacity can scarcely be less than 600 c c and may perhaps even be 650 c c

From Fig 3 it will be seen that the supposed male cast is remarkably like that of *Pithecanthropus erectus*, and if von Koenigswald's estimate of the cranial capacity of his new skull as 750 c c be correct, our South African anthropoid ape is not very far behind this primitive human type

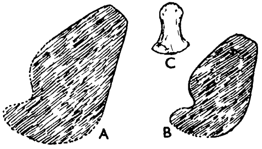

Fig 4

A Section through mandibular symphysis of *Paranthropus robustus* Broom

B Section through mandibular symphysis of ten year old male child of *Plesianthropus transvaalensis* (Broom).

C Terminal phalanx of toe of *Paranthropus robustus* Broom

(All natural size)

I give drawings (Fig. 4) of the symphyses of the mandibles of *Plesianthropus* and *Paranthropus* The former is from the symphysis of a male child of about ten years of age It is fairly complete, only the lower portion being lost. If this be compared with the symphyses of other anthropoids and of primitive human types, it will be seen that the only forms that approach it at all closely are *Dryopithecus* and the gorilla The symphysis of the adult *Paranthropus* is less satisfactorily preserved, but it can be restored with considerable confidence It is seen to be very massive—more massive than in any other known primate except the gorilla There is no very close resemblance between the symphysis in the chimpanzee and those of our fossil anthropoids

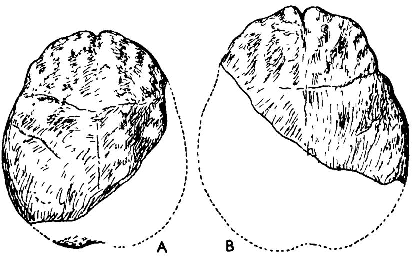

Fig 3.

A. Cranial cast of type specimen of *Plesianthropus transvaalensis* (Broom), believed to be a young female, about 440 c.c. (× ½.)

B. Cranial cast of what is believed to be an old male of *Plesianthropus transvaalensis* (Broom), about 600 c.c. (× ½)

When the Sterkfontein ape was found, I considered the geological age to be probably Upper Pleistocene, as a number of horse teeth had been found in an adjoining cave and I considered those to belong to *Equus capensis*—a fossil horse which we know survived until comparatively recently. Within the last few weeks, we have obtained many much better preserved horse teeth from the same cave, and we now find that though those belong to a large horse allied to *Equus capensis* they cannot belong to this species They will possibly prove to belong to *Equus harrisi* a species which I named ten years ago from teeth found in the diamond gravels

The positive evidence for *Plesianthropus* being Upper Pleistocene thus disappears It must belong to some part of the Pleistocene but we must wait for a more precise determination Until we have more evidence we may provisionally place both *Plesianthropus* and *Paranthropus* in the Middle Pleistocene though they were not contemporaries and the Taungs ape *Australopithecus* may be Lower Pleistocene or possibly Upper Pliocene

---

Fine Structure of the Plant Cell Wall

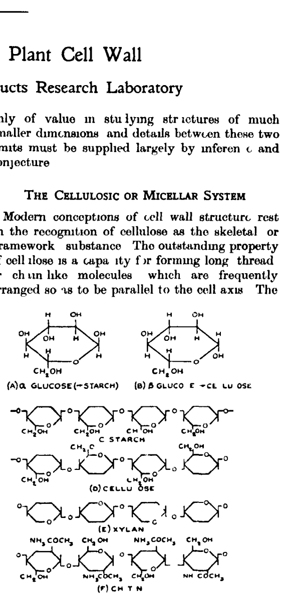
By S H Clarke, Forest Products Research Laboratory

ALTHOUGH it is almost eighty years since Nageli[1] introduced the micellar hypothesis to account for the anisotropy of certain plant structures it is remarkable how nearly his original conception satisfies the most recent discoveries It may be recalled that Nageli pictured the cell wall as composed of ultra microscopic particles to which he gave the name micelles and which were regarded as discrete units more or less like the bricks in a masonry wall In order to explain the shrinkage of wood it was assumed that water entered or left the intermicellar spaces pushing the micelles farther apart or allowing them to come nearer together and the elongated shape of the micelles was held to account for the difference between longitudinal and transverse shrinkage the optical anisotropy of the cell wall was referred to the optical properties of the micelles themselves Some revision of Nägeli s statement was however found necessary and a large body of workers rejected the conception completely postulating instead a system of continuous or connected cellulose threads or layers Neither conception is completely satisfactory and the modern tendency is to seek a compromise between the two The position has been reviewed from the point of view of physicist chemist and botanist[2,3,4,5] perhaps the fullest summaries being those of Frey Wyssling[5]* which have been freely used in the present account

The aim of the present account is not to offer a complete survey of the literature (the references quoted will lead indirectly to the more important contributions to the subject) but to give a fairly simple picture of the current conception of the different phases of cell wall structure At the outset it must be realized that a complete picture is impossible as yet because while the wave lengths of visible and ultra violet light only permit the accurate and direct observation of particles larger than about 2500 A X rays are only of value in studying structures of much smaller dimensions and details between these two limits must be supplied largely by inference and conjecture

The Cellulosic or Micellar System

Modern conceptions of cell wall structure rest on the recognition of cellulose as the skeletal or framework substance The outstanding property of cellulose is a capacity for forming long thread or chain like molecules which are frequently arranged so as to be parallel to the cell axis The molecular weight and therefore the length of the chain molecules have so far proved indeterminate there is some evidence that they may not be constant and several investigators have insisted that it is incorrect to speak of a cellulose molecule Although cellulose may be shown by X ray examination to have a definite crystal structure it has never been observed in a crystalline form



---

* Dr Frey Wyssling kindly read the draft of this review

It is insoluble in all the usual chemical solvents Introductions to the chemistry of cellulose begin with reference to glucose a hexose sugar existing in two forms (formulæ *A* and *B*) both of which may undergo condensation to form larger chain molecules Whereas the molecules of the α form combine as represented conventionally in formula *C* linkage in the β form demands the rotation of alternate molecules through 180° (formula *D*) The higher degree of symmetry in the chains of β molecules is apparently accompanied by a greater stability and it is probable that on this rests the importance of the β glucosidic cellulose as the fundamental framework constituent while the less stable α glucosidic molecules of starch occur as reserve materials which are of a more temporary importance in the life of the plant It is of great interest that xylan (a pentosan commonly occurring with cellulose in the cell walls of wood) and chitin (the framework substance of fungal cell walls) may have a fundamentally similar chain structure as shown in formulæ *E* and *F* respectively it has been suggested[8] that individual chain molecules may include a variety of units for example glucose xylose glucuronic acid

X ray diffraction studies have revealed the dimensions of the spaces occupied by the individual glucose residues of the cellulose chain molecules and by the same method the length of the chains has been variously estimated at between 600 A and 750 A that is 120 150 glucose residues Viscometric determinations however give the chain molecules a length of ten or twenty times that indicated by X rays The absolute legitimacy of both methods has been questioned and it is not possible at present to decide which result is the more likely to be correct there is reason to believe however that further light will be thrown on the subject by studies of the end groups of the chains which are being carried out in several laboratories In spite of the contention of some investigators that the chain molecules may extend unbroken from end to end of the cell it is widely believed that the figures yielded by X ray studies and by viscometric determinations are both approximately of the correct order of magnitude and that the chain molecules are much shorter than the cells In this connexion it is of interest that a fairly close relation exists between the strength of whole fibres and the length of the cellulose chain molecules as revealed by the viscometric method[7] it has been shown that maximum strength is reached in chains of about 2 000 glucose residues and that further increase in chain length does not affect strength Hydrolysis such as accompanies the attack of certain fungi results in the breaking of the cellulose chains into shorter units and in a lowering of the tensile strength

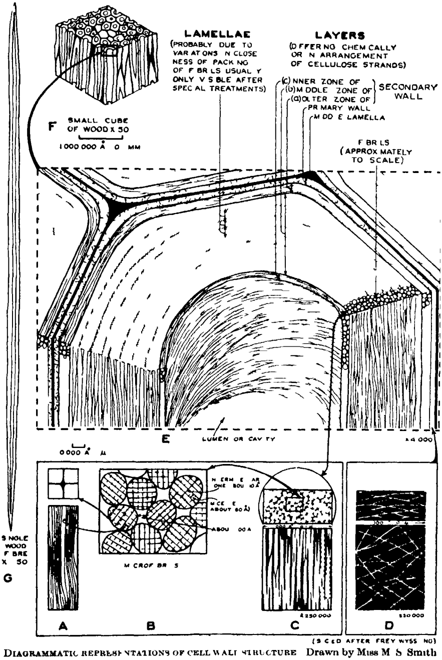
Plant fibres may be completely delignified without disintegration so that the cellulose apparently forms a continuous system throughout the cell wall It is also possible to remove the cellulose from the cell walls of some tissues leaving behind what is presumed to be a continuous skeleton of lignin In consequence the cell wall is regarded as having continuous and interpenetrating systems of cellulose and lignin The structure has been likened to reinforced concrete in which the iron strands represent the cellulose framework and the concrete the lignin and other substances From X ray diffraction patterns however the impression is gained that the cellulose chain molecules occur in discrete aggregates about 50 A in diameter and more than 1000 A in length This impression is given by both dry and water saturated material and it would therefore appear that water penetrates between the aggregates without disturbing their internal crystal structure In consequence they have been regarded as corresponding to micelles and they are so named albeit with a somewhat different meaning from that of Nageli The cellulose system is therefore visualized as continuous and yet able to give the impression of being composed of discrete micelles when examined by X rays

Fig *A* illustrates a feasible conception of a molecular arrangement fulfilling these conditions The cellulose chain molecules are represented as lines which are not completely parallel but show slight local variations in direction so that here and there lens shaped spaces occur between adjacent chains There are however many zones in which the chain molecules are parallel (indicated in Fig *A* by thicker lines) and since it is only such zones of regular arrangement that influence the X ray diffraction patterns the illusion of discrete aggregates is produced Actually the aggregates are linked by molecules which extend from one regular zone to another so as to maintain the continuity of the system In Fig *C* this condition is illustrated on a smaller scale the white zones indicate the distribution of the cellulose and the dotted lines the regions in which the chain molecules are parallel It may be observed from the dimensions given that the two illustrations (Figs *B* and *C*) do not completely correspond This lack of correspondence is doubtless explained by the fact that they were originally produced independently and in all probability the intermicellar spaces and the larger capillaries actually intergrade continuously in size

Adjacent glucose residues within a chain molecule of cellulose are united by primary valences but the nature of the attraction between laterally adjacent chain molecules has not yet been fully elucidated It is generally supposed however that the chain molecules are united laterally by van der Waals cohesion Frey Wyssling mentions in criticizing the hypothesis of discrete micelles that this force must also be invoked in seeking to explain the attraction between micelles It is clearly unsatisfactory to be compelled to resort to a single force to explain two distinct phenomena for example it is difficult to explain on such grounds why water only enters the intermicellar spaces and does not penetrate between the chain molecules within the micelles

The Intermicellar System

It is believed that the intermicellar system is normally occupied by lignin and related substances Whatever their composition these materials produce no effect on the X ray diffraction pattern so that they are apparently non crystalline Although they occupy a continuous system the intermicellar materials appear to have little or no influence on the tensile strength of the cell wall they bestow on the cellulose system however an increased rigidity and incidentally increase the resistance to compression Information regarding the intermicellar system has been obtained by impregnating cell walls with solutions of silver or gold salts, and precipitating crystals of the metals in the intermicellar spaces so as to make an impression on the X ray diffraction pattern In this way it has been



Diagrammatic representations of cell wall structure Drawn by Miss M S Smith

A Cellulose chain molecules showing here and there zones of regular and parallel arrangement (the micelles indicated by X rays)

C Cellulosic and non cellulosic systems in the secondary wall Cellulose white non cellulosic materials black transverse section above longitudinal section below Large circle indicates approximate size of fibril at same magnification (Note that the dimensions given by the author of Figs B and C do not correspond exactly but they serve to indicate the approximate sizes The linking arrows have been inserted by the present writer)

D Cellulosic and non cellulosic systems in the primary wall Cellulose white non cellulosic materials black transverse section above longitudinal sections below

E Small piece of wood showing the relative sizes and dispositions of the cell wall constituents as revealed by microscopic examination

F Small cube of wood fibres magnified 150 times

G Single wood fibre magnified 150 times

estimated that in their widest parts the spaces sometimes reach a width of 100 A that is about twice the diameter of the micelles Combining the data obtained from various X ray investigations the picture in Fig *B* has been suggested as representative of the condition in a typical cell wall It may be observed that the intermicellar spaces vary considerably in size and that the micelles themselves are aggregated into microfibrils separated by spaces rather larger than the usual intermicellar spaces In his studies of wood water relationships Barkas[8] reached the conclusion that there is a continuous gradation in size of the space system ranging from the botanical capillaries down to the colloidal structures and it would therefore appear probable that the intermicellar spaces and the spaces between the microfibrils are continuously graded in size

An interesting sidelight on the nature of the intermicellar system is afforded by the change in the refractive index of water entering the system Although the refractive index parallel to the chain molecule axis of dry cellulose by sodium light is 1 596 and that of water is 1 333 the refractive index of cellulose when swollen by 25 per cent of its volume of water is not noticeably less than that of dry cellulose whereas an index of about 1 536 might be expected if the water and cellulose were merely mixed Moreover the volume contraction and the evolution of heat which accompany the swelling of wood by water indicate some form of combination between the water and the wood cell wall Frey Wyssling suggests that the original function of the intermicellar spaces is bound up with the growth of the cell wall and that in the early stages of formation the protoplasm may occupy these spaces

MICROSCOPIC STRUCTURE

The phases of cell wall structure described above are invisible because the units involved are much smaller than the wave length of light There is a gap in our knowledge between the microfibril and the smallest particles distinguishable microscopically because no form of direct or indirect observation is yet available We must now therefore turn to the visible structure built on the micellar framework

Kerr and Bailey[9] have reviewed the nomenclature of the cell wall marshalling the evidence that in typical cells the wall has three distinct regions (Fig *E*)

(1) The *middle lamella* or intercellular substance is formed from the cell plate at cell division and is shared by adjacent cells it is very thin completely isotropic and composed largely if not entirely of polyuronides

(2) The *primary wall* is developed from the cambial wall it is anisotropic and is composed of cellulose with large proportions of hemicelluloses pectic substances and lignin It is laid down during the period in which extension growth takes place and this is reflected in the structure of the cellulose framework Fig *D* is an attempt to portray the relative proportions and arrangements of the cellulose framework and the intermicellar system of the primary wall on a scale comparable with Fig *C* which represents the condition in the secondary wall It may be observed that the cellulose strands are much more slender in the primary wall and Frey Wyssling suggests a more irregular arrangement as a consequence of growth by intussusception the intermicellar zones occupy a larger proportion of the whole in keeping with the fact that the primary wall is much more heavily lignified than the secondary wall It will readily be appreciated that if the tensile strength of wood depends on that of the cellulose strands it is likely to be limited by the zones in which these strands are least strongly developed and it is not surprising that in green wood tension failures normally occur in the region of the middle lamella and primary wall[10]

(3) The *secondary wall* is composed of cellulose or of varying mixtures of cellulose hemicelluloses lignin pentosans etc This wall is presumably produced mainly for mechanical reasons it is incapable of extension growth and during growth is added to by apposition Three distinct zones are frequently to be seen an outer zone (*a*) which is distinguishable in transverse sections from the middle zone (*b*) on account of a difference in refractive index It has already been mentioned that cellulose is anisotropic and the difference in refractive index between these two zones is due to the fact that in the outer zone the cellulose strands are arranged in a flat spiral (Fig *E*) whereas in the middle zone they are as a rule approximately parallel to the cell axis For this reason the outer and inner zones are readily distinguished when examined between crossed nicols The outer and middle zones are usually identical or similar in composition but there may be variations in the substances occupying the intermicellar spaces In some cells an inner zone (*c*) is present differing from the middle zone (*b*) in composition and in that the cellulose units pursue a flat spiral (Fig *E*)

Within this general scheme much variation is possible in different tissues and in the cells of different species In some cells no secondary wall is found while in others it is very strongly developed and shows within itself elaborate zonations Bailey and Kerr[11] illustrate fibres in the secondary walls of which the inclination of the cellulose units alternates in several successive layers, reminiscent of the alternations in grain direction in plywood The same authors illustrate other fibres in which the secondary walls show several zones caused by variations in the intensity of lignification these zones may be concentric radial or radio concentric, and Bailey and Kerr have shown the arrangement to be influenced by geotropic or phototropic stimuli operating on the growing tree

Zonations of the types described due either to variations in chemical composition or to variations in the arrangement of the cellulose units affecting the optical anisotropy of the cell wall are known as layers A much finer type of concentric zonation termed lamellation occurs in the walls of many plant fibres Although it may accompany layering lamellation is of a different nature and is not revealed microchemically or by polarized light A single layer may include several lamellæ Lamellæ may be observed in the thick walled fibres of certain species when thin transverse sections mounted in liquids of suitable refractive index are examined at very high magnifications they may be revealed also in the fibres of many other species when transverse sections are considerably swollen in dilute cuprammonia From calculations based on their dimensions in swollen material it has been estimated that in the natural state the lamellæ of the cotton hair are 0·4 μ (= 4000 A) or less in thickness In swollen sections each lamella is seen to comprise two concentric zones differing in brightness and it is purely on account of these variations in optical density that the lamellæ are visible It has been established that in the cotton hair the lamellæ are caused by diurnal fluctuations in light and temperature during the growing period[13] and although the methods used in studying the lamellations of cotton hairs cannot be applied to cells in other parts of the plant it has been suggested that lamellation in xylem fibres is of a similar nature[3]

By means of controlled chemical and mechanical treatment[5,14] the cellulose wall may be dissected into tenuous threads known as fibrils these are of indeterminate length and their diameter has been variously reported as between less than 1000 A to about 5000 A By further dissection the fibrils may be broken into smaller bodies described as dermatosomes fusiform bodies etc the diameter of which is reported to be 5000 A or less and the length of which is from about 1000 A to 1500 A The descriptions of various investigators show discrepancies which are no doubt due to the observation of different tissues of different species, to variations in the technique of dissection and perhaps to variations in the degree of swelling at the time of measurement All that can be said is that by dissection the wall can be broken into fibrils and these into smaller units Bearing in mind that dissection is only accomplished as the result of severe chemical treatment some reserve is necessary in attempting to construct from these units a picture of the cell wall in its original state Nevertheless the rough correspondence between fibril diameter and the dimensions of the lamellæ suggests that the separations are not entirely fortuitous Bailey and Kerr[1] actually attribute the lamellæ to variations in the closeness of packing of the fibrils or in the number of fibrils per unit area of cross section Some authors have suggested that the dermatosomes and the fibrils are coated with a non cellulosic material after the fashion of mortar in a masonry wall If this be the case we are again thrown back on the properties of the mortar as the ultimate source of the tensile strength whereas it has already been stated that there is much evidence for believing the cellulose to be mainly responsible In this connexion it may be mentioned that Farr and Eckerson[8] have described what they believe to be the laying down by the protoplasm of minute particles of cellulose coated with some pectic material which acts as a cement in the cell wall Weighty objections to this view are summarized by Anderson and Kerr[2]

From microscopic evidence then we are able to say that the plant cell wall is ordinarily composed of concentric layers differing in the relative proportions of cellulose and other constituents The layers appear to be built up of fibrils long slender threads of cellulose the direction of which is often parallel to the main axis but is subject to variation in different layers The closeness of packing of the fibrils is subject to periodic fluctuation as a result of which the cell walls frequently include a large number of extremely narrow lamellæ The fibrils may be dissected chemically into small fusiform bodies or dermatosomes It is inferred from the behaviour of suitably treated material that both the cellulose and the non cellulosic constituents of the cell wall form continuous systems which are finely interpenetrating and it is apparent that the cellulose system is mainly responsible for the tensile strength whereas the non cellulosic constituents have a stiffening effect which results in increased resistance to compression From X ray evidence it is concluded that the fibrils are themselves composed of microfibrils which in turn consist of aggregates of micelles The micelles are aggregates of cellulose chain molecules Each chain molecule includes a large number of glucose residues but it is not yet known whether the chains are of uniform length or even of uniform constitution In all probability neither micelles microfibrils nor fibrils are discrete units, and their apparent independence is illusory and is due to peculiarities in arrangement that affect certain types of observation It seems probable that the spaces between the cellulose units such as might contain water, non cellulosic wall constituents or protoplasm at certain stages in the life of the cell are of a continuously graded size and may be regarded as the successive ramifications of a single system

Obituary Notices

Dr C C Carpenter

THE technical press has paid tribute in full measure to the memory of Charles Carpenter to his many outstanding achievements in the gas industry to his ability to manage and to organize to his intense consideration for his fellow workers as displayed in his zealous furtherance of co partnership (see also NATURE Oct 8 p 636) There remains the need to express something of the man himself a difficult task with anyone but doubly so with one of his complex personality

Dr Carpenter was a far greater man than his contemporaries realize His shyness the habit of working alone which had developed almost to an inability to work with others the reluctance to take part in those co operative efforts which are so fashionable to day, have collectively resulted in limiting the number of those to whom he was personally known during the later years of his life Possibly to many of us now active in contemporary spheres he has been a memory of past deeds rather than the present embodiment of an activity both mental and physical which his colleagues and intimates knew he had preserved until stricken by illness

My friendship with him dates twenty five years back when he was already distinguished and his habits formed He had consented to become president of the Society of Chemical Industry at a critical time when the status of that industry in England had been brought low by neglect Some of us were making a great effort to reform the Society, which we regarded as a potential instrument for progress, and to change its complacent attitude of parochial conservatism to one of vigorous action Carpenter proved an ideal chairman at many difficult meetings and won the confidence of all by his firm and sympathetic handling of delicate situations When it was realized that the troubles of the chemical industry could best be overcome by the formation of an entirely new Association of British Chemical Manufacturers, Dr Carpenter was the obvious and universal choice for its first chairman In th capacity he displayed his best qualities in the handlin of the initial difficulties including the reconciliatio of conflicting interests and so laid a firm and sur foundation for its future success

This achievement in sooth a considerable one might have tempted Dr Carpenter to continu collective industrial leadership at a time whe leaders of his calibre were so much in demand, an he had many requests to do so, but the work wa foreign to his real nature and he preferred to immers himself wholly in the problems of his gas companie to their great advantage

Carpenter s qualities in his daily work have be emphasized by others His attention to detail th desire to find a reason for everything the refusal t put up with anything but the best his pertinacity to pursue a matter to the end, his remarkable powe of continuous work and numerous other attribute combined to make him the personality he was durin the long working day The high standard he set fo himself made him expect the same of others an caused him perhaps to be lacking in sympathy towards lesser mortals This made him unduly severe when displeased and over generous whe giving reward Hazlitt somewhere defines genius as the power of producing excellence, from this point of view, Carpenter certainly was a genius

It was given to a few intimates to know Charl Carpenter on his artistic side Evenings after dinne in his large comfortable room in Chelsea dwell in my memory Spartan himself, he provided good chee for his guests, and the range of conversation displaye a human personality remote from the austere chair man presiding in his board room The boon of artistic enjoyment makes itself manifest in many ways To some it comes through the gradations of the bitten line, others find revelation in broader ton masses put on with a palate knife, more of us like my late father find intense happiness in colour A clas apart find supreme joy in the melodies of music, an to these belonged Carpenter He derived great pleasure from his gramophones ingeniously arranged to play both sides of a record consecutively without a break the opera and concerts were his one relaxation and the only accepted reasons for his going out in the evening His library was peculiar in more than one respect He took great pride in the workmanship and binding of his books and regretted the decline in that craft His tastes would be called old fashioned literature of the French sentimentalists and George Moore were among his favourites He detested anything shoddy or imperfect

This attitude is reflected in Dr Carpenter's annual addresses as chairman, which instead of the usual platitudes contained studied discourses on matters of moment to the policy of the company in which the meaning of every word had been weighed an immense amount of time and trouble went to the preparation of these

How shall we reconcile the dual characters the shy sentimental music loving artist with an intense sense of perfection and a hatred of shams the reasoning intrepid engineer seeking to put into his creative work the artistic expression which he could not by his own hand achieve with pen or piano the great leader setting so high a standard for himself that he felt he could not trust to others to execute his plans and so becoming lonely, unable to depute in the way that modern industry demands carrying most of his burdens himself and in later years almost unwilling to be helped

Each one of us is the integration of our many component parts, and who shall judge if the result is short of the ideal Charles Carpenter was a great engineer a cornerstone of the gas industry to which he devoted his life the best of masters to his thousands of work people, to whom more than anything else he brought fair dealing and security and a complex and lovable personality to his intimates We shall think of him at his best and remember how in life he did

Strive and hold cheap the strain,
Learn, nor account the pang,
Dare, never grudge the throe'

Prof W H Merrett

Prof W H Merrett formerly assistant professor of metallurgy at the Royal School of Mines who retired from his post rather more than a year ago, died after a short illness on October 29 last He was sixty six years of age A fortnight before his retirement he had a severe stroke from which he never really recovered It was followed by another, after an interval of little more than a year, which proved fatal

Merrett received his school education at St Olave's School, London, during which time he gained a number of valuable prizes for science, and obtained a Royal Exhibition of the Board of Education In 1891 he entered the Royal School of Mines, and after spending three years there was awarded a first class in the associateship of the School in metallurgy This was during the tenure of the late Sir William Roberts Austen of the professorship of metallurgy In addition to holding this post Sir William was chemist and assayer of the Mint and it was there that he carried out his researches on metals and alloys Thither Merrett proceeded after graduation and acted as an assistant in the prosecution of these researches during the next seven years It was a particularly interesting period in the development of that branch of metallurgy which is to day known as metallography These were the early days of the subject and the foundations were still being laid Roberts Austen was himself one of the pioneers he was a member of the Alloys Research Committee of the Institution of Mechanical Engineers and published five reports of experimental work in all It is with the work for the fifth report that Merrett was particularly associated acting as an assistant to Roberts Austen and Stansfield

The method of investigating the thermal inversions of metals and alloys at that time by taking cooling and heating curves was due to the late M Osmond using the thermo electric pyrometer introduced by the late H le Chatelier In this method the co ordinates were time and temperature and while it was quite satisfactory in the upper ranges of temperature it was not so suitable for the lower ranges where the rate of cooling becomes very slow Roberts Austen and Stansfield accordingly devised the differential method in which a neutral body was also present (Strictly speaking it is not a differential but a difference method since no differential co efficient is involved) In this method temperature and difference of temperature were the co ordinates, and accordingly the rate of cooling did not matter Moreover, accidental fluctuations in the rate of cooling of the furnace were cancelled out This method could be made very sensitive and by its means accurate thermal curves of iron and carbon steels were obtained In the Fifth Alloys Report is published a curve of a sample of electro deposited iron which had cooled from 1150° to 100° C It represented the most skilled piece of experimental work in this field at that time In addition this research contains a number of photomicrographs of steel structures of great clearness Merrett developed a skilful technique in both these branches of metallography, which contributed very much to the value of the report in question He was the first to apply the electric arc light as a method of illumination in the metallographic microscope The Sixth Report to the Alloys Research Committee had been begun during Roberts Austen's lifetime but owing to his illness and death it was completed by the late Prof Gowland with the assistance of Merrett This deals with the heat treatment of steel

Roberts Austen was also a member of a War Office and Admiralty Committee on Explosives and Ordnance In this capacity he carried out a number of investigations most of which were of a strictly confidential nature These comprised (*a*) the nature of erosion in gun tubes (*b*) the effects of various additions of nickel, chromium, tungsten and manganese on the mechanical properties of gun steels, and (c) the effects of heat treatment on gun steels Merrett carried out all the experimental work on which these reports were based He conducted an investigation, also under Roberts Austen, for the Board of Trade on the St Neots railway disaster This examination was published *in extenso* as a Blue Book in 1900, and the accident traced to a broken rail He found evidence of a 'martensitic structure, which is associated with great brittleness on its surface A temperature of at least 800° C is required to produce this Merrett was at least partly if not wholly responsible for a new lyddite shell exploder, for which a secret patent was taken out by the late Lord Haldane He was also largely concerned with the development of ammonium nitrate for use as an ingredient of explosives which led to the introduction of amatol

In 1901, Merrett was appointed instructor in the Metallurgy Department of the Royal School of Mines, and spent the remainder of his professional life there until his retirement He rose to the position of assistant professor He was an admirable teacher, clear and inspiring This side of his work appealed to him very much He was always anxious that his students should conduct themselves with credit in their examinations, and this led him sometimes to take a kindlier view of their performances than the results warranted As early as the age of sixteen years he showed his taste for military work and joined the 3rd Middlesex Artillery in 1888 He was transferred as a sapper ten years later to the newly formed Corps of London Electrical Engineers He rose to the rank of major and was mobilized for active service on July 29, 1914 During the Great War he was in charge of various coast defences and anti aircraft units Afterwards his scientific knowledge was made available to the Ordnance College as instructor in metallurgy, chemistry and explosives In 1926 he retired from military service on reaching the age limit and was awarded the Territorial Decoration and Long Service Medal

Merrett was a member of many scientific societies, a governor of the School of Metalliferous Mining at Camborne and a member of council of the Institution of Mining and Metallurgy The writer was a colleague of his at the Royal School of Mines for twenty three years He possessed qualities which made him one of the most delightful of fellow workers Some of these such as punctuality and reliability, could probably be traced to some extent to his military training Others, such as his perfect courtesy, generosity and good temper, were natural to him It is impossible to think that he had an enemy His many friends mourn the loss of one of the kindest and most unselfish of men H C H C

We regret to announce the following deaths

Mr J F Bailey director of the Botanic Gardens, Brisbane, from 1905 until 1917, and director of the Botanic Garden, Adelaide from 1917 until 1932

Prof E M East, professor of genetics in Harvard University aged fifty nine years

Admiral Sir Herbert Purey Cust, K B E , C B formerly hydrographer to the Navy, on November 11 aged eighty one years

News and Views

The Royal Society

His Majesty the King has been graciously pleased to approve the recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year to Dr F W Aston, F R S in recognition of his discovery of the isotopes of non radioactive elements and to Prof R A Fisher, F R S , in recognition of his important contributions to the theory and practice of statistical methods The Council of the Royal Society at its recent meeting recommended the following for election as officers and council at the anniversary meeting on November 30 ***President***, Sir William Bragg ***Treasurer*** Sir Henry Lyons , ***Secretaries***, Prof A V Hill and Prof A C G Egerton , ***Foreign Secretary***, Sir Albert Seward , ***Other members of the Council***, Prof F C Bartlett, Prof F E Fritsch, Prof M Greenwood, Mr H L Guy, Sir Thomas Holland, Dr A D Imms, Prof C K Ingold, Prof G B Jeffery, Prof J Mellanby, Prof J Proudman, Dr F L Pyman, Prof O W Richardson, Prof W W C Topley, Prof D M S Watson, Prof R Whiddington, Prof R Whytlaw Gray

Prof Enrico Fermi

The Nobel Prize for Physics for 1938 has been awarded to Prof E Fermi, professor of theoretical physics in the University of Rome, and his work in connexion with artificial radioactivity induced by neutrons is specially mentioned in the award Bombardment of the nucleus with neutrons is peculiarly effective in producing nuclear reactions because the neutron does not experience the strong electrostatic forces which oppose the approach of a proton or α particle Fermi in 1934 showed that most nuclei, even the heaviest which are most resistant to charged particles, are disrupted by neutrons with the formation of new radioactive nuclei In the same year, he discovered that the effectiveness of neutron bombardment is greatly increased in the presence of masses of water or paraffin, and concluded that the neutrons are slowed down by collisions with hydrogen nuclei in these substances, and that the slow neutrons have a high probability of entering and disrupting nuclei Prof Fermi has, however, made other outstanding contributions to atomic physics In 1926 he applied Pauli's exclusion principle to deduce a new kind of statistics for electrons (Fermi Dirac statistics) He applied this to the assemblage of electrons in an atom (Thomson Fermi atom model) and it has become the basis of the modern theory of electrons in metals In 1934 he devised a theory of β decay, starting from the view that a β particle is emitted when a neutron in the nucleus turns into a proton The distribution of energies in a continuous spectrum requires that a neutral particle (neutrino) be emitted with the β ray This theory has formed the starting point for many more recent discussions Fermi has also published work on spectroscopy on quantum electrodynamics and, with Rossi, on the *deflection of cosmic rays in the earth's magnetic field*

Dr W D Lang, FRS

DR WILLIAM DICKSON LANG who retires from the keepership of geology in the British Museum (Natural History) at the end of the year, has made notable contributions both to palæontology and to geology While occupied with curatorial duties he has studied especially polyzoans and corals, and in classifying them he has always sought for underlying principles Like palæontologists studying other groups, he soon recognized parallel lineages in the evolution of these fossils as he traced them through geological time, and he found corresponding grades in the same order in each parallel lineage, showing that there was a definite common trend, as he termed it Natural selection, therefore, did not work on indefinite individual variations but on trends which were orthogenetic or in a certain fixed direction Dr Lang contributed several valuable papers on this subject to the *Proceedings of the Geologists Association*, and he summarized his results in discussions at the centenary meeting of the British Association in 1931

DEALING with animals which retained the complete skeleton of a lifetime in each individual Dr Lang could also study the growth stages, and he was convinced of the truth of the doctrine of recapitulation (the immature stages of an organism repeating more or less exactly the adult stages of its ancestors) He described it as "a guiding principle for palæontologists Dr Lang also recognized that the calcareous skeleton of the polyzoans, when once started in a lineage, often proceeds to superfluity and eventually leads to extinction He treated this subject in a memoir in the *Philosophical Transactions* in 1919, and in two valuable volumes of the British Museum Catalogue of Cretaceous Polyzoa, 1921–22 Dr Lang spent many vacations in studying the succession of zones in the Lias of the Dorset coast In 1924 he contributed to the *Proceedings of the Geologists' Association* a remarkably detailed map of those formations, and during more recent years he and other specialists have made a detailed examination of the fossils he collected His interests have always been varied, and during the Great War he investigated insects which spread disease, eventually preparing an exhaustive 'Handbook of British Mosquitoes', which was published by the Trustees of the British Museum in 1920

Prof A V Hill, OBE, FRS

THE Guthrie Lecturer of the *Physical Society* this year was Prof A V Hill Foulerton research professor and secretary of the Royal Society who chose as the title of his lecture delivered on November 11 The Transformations of Energy and the Mechanical Work of Muscles Prof Hill is a Cambridge man, where under Langley he devoted two years to research on the heat produced by living tissues Here Hill found a congenial and stimulating environment for those working in the laboratory at the time included such well known figures as Anderson, Barcroft Fletcher Hardy Hopkins and Keith Lucas Prof Hill's success may be said to be due to his appreciation of the basic essentials of a problem, to his knowledge of the methods by which such problems may be solved to his ability to design the apparatus required by such methods, and lastly to his skill in constructing the necessary apparatus himself A first rate athlete he was specially interested in the physiology of athletics It was he who showed that energy is developed in muscle at two different times during a single contraction Two pieces of apparatus have entered largely into these studies, namely, extremely delicate thermopiles and galvanometers which have a short period and great sensitivity While the study of energy of contraction of muscle has been Hill's main line of research a number of branch lines have interested him from time to time mostly on biophysical subjects, for example the measurement of small differences of osmotic pressure and the heat produced in nerves during the passage of impulses During the Great War, Hill was director of research on anti aircraft defence In 1920 he became professor of physiology in Manchester, and in 1923 professor of physiology at University College, London Prof Hill has been honoured by several foreign universities and learned societies and in 1922 he received the Nobel Prize for Medicine

Energy Transformations in Muscles

IN his Guthrie Lecture on the subject Prof A V Hill pointed out that the study of the heat given out by muscles in relation to the work done by them is one of the classics of physiology Until recently, however the matter appeared much more complicated than it really is owing to technical difficulties These have been overcome by the use of a very rapid recording system and an insulated thermopile only 0 002 inch thick Some very simple relationships have now emerged An active muscle liberates energy in three forms in maintaining a contraction as heat, in shortening as heat in shortening against load, as work its behaviour in any circumstances is deduced from the resultant of these three *Rate* of total energy liberation of a muscle is determined by the load upon it, increasing as the load decreases This allows a simple equation to be deduced for the relation between speed and load The constants of the equation are the same whether they are obtained by thermal or by mechanical measurements The fact that a muscle does less external work when shortening at a higher speed has led to the hypothesis that muscle is endowed with 'viscosity', attributed to a lag in the rearrangement of its molecules, as the external form of the contractile elements changes. This viscosity hypothesis is, however, altogether unnecessary; for the decrease of force and work with increased speed can be deduced from the manner in which the energy liberation is regulated. Some applications were also described. The maximum power developed by a muscle is with a load about three tenths of the maximum load it can bear. The highest efficiency (work/total energy) is with a load of about 0·45 of the maximum. These are near enough for maximum power and maximum efficiency to occur very nearly at about 37 per cent of the maximum load. These results obtained with frog's muscle almost certainly apply, though possibly with different constants, to man; and it would be very important to find out and to determine the constants of human muscle. The technique required would be a very different one.

Anthropoid Evolution in South Africa

DR. ROBERT BROOM continues to provide sensational news from South Africa for anthropologist and palæontologist. In another column of this issue (see p. 897) he reports further finds of relics of South African fossil anthropoids which, if anything, surpass in interest the remarkable discoveries he has already recorded recently in these columns. From the site on which was found the Kromdraai skull, he has now recovered three bones or parts of bones, the right humerus, the ulna and one of the toe phalanges of *Paranthropus* which, as his nomenclature indicates, he places, on the evidence of the skull, very near the line of man. The new evidence fully bears out his conclusion, for as he states, these bones, which on the balance of probabilities must be associated with the skull, are "nearly human". Further, and this is the most interesting feature of the discovery, they, and more especially the toe bone, must be interpreted as pointing to *Paranthropus* having walked erect. In other words, the upper limbs of this type were already freed from the duties of locomotion to undertake those functions which were to play a predominant part in forwarding the development of the specific characters of the brain of *Homo sapiens*.

THIS eminently reasonable interpretation of the Kromdraai finds removes the element of surprise from the further discoveries from Sterkfontein, which Dr. Broom records; but it adds to their significance in mutual corroboration as between the two series of discoveries. At Sterkfontein, on the site on which he had previously discovered *Plesianthropus transvaalensis*, an advance towards the human on Prof. Raymond Dart's *Australopithecus*, or ape-man from Taungs, Dr. Broom has also found the distal end of a femur and part of the brain cast of, it is argued, a mature male. Not only would the fragment of femur suggest that this type of fossil anthropoid also had attained bipedal status, but in addition the brain cast, when reconstructed, would place the capacity of the brain of *Plesianthropus* next in the scale of measurement, so far as at present known, to the recently discovered specimen of *Pithecanthropus* from Java. *Pithecanthropus*, no longer in danger of being classed as a gibbon, is definitely above the human border line. The new evidence from Kromdraai and Sterkfontein, taken in conjunction with the evidence of the symphyses, which Dr. Broom further records, would indeed seem to afford warrant for the view that we have been given a glimpse of the evolutionary process at a moment when what has been regarded hitherto as man's prerogative—the permanent assumption of the erect posture—had not long taken place. The difficulty in the way of regarding the South African fossil series as forming part of the human evolutionary process, though of course significant by analogy, on the ground of its relatively late date, to which Sir Arthur Keith has directed attention, is reduced though not eliminated, by Dr. Broom's evidence for a revised dating.

Scientific Associations of the Lubbock Estate

THE public acquisition of the High Elms estate in Kent as part of London's 'green belt', is an event of note in the history of science; for this was the home of the Lubbock family from 1808. In that year, Sir John William Lubbock acquired the nucleus of the property, some 270 acres; by later accretions the estate reached its present extent of nearly a thousand acres. A second Sir John William Lubbock was the first to bring scientific fame into the annals of the family: his observations of tidal and lunar phenomena and in physical astronomy ranked him high, and he was elected fellow of the Royal Society when barely twenty-seven years old. He worked also on the mathematical doctrine of probability and applied it practically to the subject of life assurance. He became the first vice-chancellor of the University of London. He built the present mansion of High Elms, extended the property, and greatly beautified it by planting many of the splendid trees which grace it now. He was followed by a still more famous son, Sir John Lubbock, afterwards Lord Avebury, who, born in 1834, spent nearly all his life there, and succeeded to the property in 1865. It is well known that on the scientific side his extraordinary career was influenced, not only by his father, but also, profoundly, by Charles Darwin.

IN fact, the assurance of the preservation of High Elms rounds off, as it were, a unique scientific memorial. For Down House is less than two miles from High Elms, and Down House, as is well known, is preserved as a memorial to Darwin by the gift of Sir Buckston Browne to the British Association. It is on record that Sir John William Lubbock hailed as a great event the news that Charles Darwin was coming to live at Down House in 1842, and it was not long before intimacy was established between the two houses. Between Darwin, in his thirties, and John Lubbock, not yet in his teens, a close friendship grew and endured until Darwin's death in 1882, when Lubbock paid final tribute to his scientific master by drawing up the memorial which petitioned the Dean of Westminster that Darwin should be buried in the Abbey. It is good to know that not only the homes of these two renowned men but also some at least of the countryside which they knew and loved, are safe from future change though suburban London lies so near.

Jubilee of the Pasteur Institute, Paris

NOVEMBER 14, 1938, marked the fiftieth anniversary of the inauguration of the Pasteur Institute of Paris as the result of international subscription, but the actual celebrations have, owing to the recent crisis, been postponed until December 27, the anniversary of the birth of Pasteur. The spacious building in the Rue Dutot, recently renamed Rue du Dr. Roux, took the place of the small laboratory in the Rue d'Ulm where so much of Pasteur's valuable work had been carried out. Although his labours were interrupted by ill health during the rest of his life, he received the assistance of a number of collaborators and pupils, notably Roux, Yersin, Metchnikoff, Chamberland and Calmette. The institute at once became an important centre for bacteriological research, the results of which were published in the *Annales de l'Institut Pasteur*, founded in 1887, in which epoch-making papers appeared on rabies, anthrax, diphtheria toxin and antitoxin, and experimental syphilis, among many other important subjects.

IN 1903 the *Annales* were supplemented by the *Bulletin de l'Institut Pasteur*, which contained, as the title indicated, reviews and summaries of work on bacteriology, medicine, general biology, physiology and biological chemistry *in relation to microbiology*. The close association of the Institute with clinical medicine was shown by the subsequent establishment of the Pasteur hospital for infectious diseases on the opposite side of the street. Pasteur died on September 28, 1895, and after a public funeral was laid to rest in a magnificent tomb in a crypt of the Institute. Since his death three eminent men have been in charge of the Institute, namely, Émile Duclaux (1895–1904), Émile Roux (1904–1933) and Louis Martin, the present director. Metchnikoff, Chamberland and Calmette were for some time sub-directors. Numerous Pasteur institutes modelled on that of Paris have been built in different parts of the world, such as those at Saigon (1889), Tunis (1893), Lille (1895), Algiers (1910) and Athens (1920).

Violent Earthquake of November 10

IT is reported from the Air Ministry that an earthquake of great violence was recorded on November 10 at Kew Observatory at 20 h. 30 m. 7 s. G.M.T., a second movement following about half an hour later. The displacements of the ground at Kew were about one tenth of an inch, and the epicentre of the shock was 5,100 miles away. This earthquake has been reported from observatories throughout the world. From New York it appeared to be at a distance of 3,400 miles and from Pasadena, where the needles nearly went off the paper of the recording seismographs, it appeared to be 2,550 miles. From the Dominion Observatory, Wellington, New Zealand, the epicentre appeared to be distant 6,000 miles, and from the Villa Ortoza Observatory in the Argentine more than 6,000 miles. At Mr. J. J. Shaw's Observatory at West Bromwich it was reported to have had the largest amplitudes recorded in thirty years and to have been of greater violence than the Quetta earthquake of 1935 or the Tokyo earthquake of 1923. The shock was felt by people in Alaska, though no damage was done, and it is reported in the *Yorkshire Post* to have been felt in Leeds. A small seismic sea wave was apparent on some of the Hawaiian Islands. All this evidence seems to point to a submarine epicentre in the North Pacific Ocean near the Aleutian Islands and to the south-west of Alaska. This area is known to be one of the unstable regions of the earth, about fifty large and many more small earthquakes being recorded from the vicinity between 1913 and 1930.

Earthquake near Vienna

AN earthquake with an epicentre near Vienna occurred about 4h. G.C.T. on November 8, doing some damage to property but causing no casualties. An earthquake in this region is most unusual and the last one of any importance was in 1927 on October 8 at 19h. 48m. 55s. G.C.T., with epicentre lat. 48° 04′ N., long. 16° 35′ E. It was discussed very thoroughly by Dr. V. Conrad of Vienna, who confirmed from the records the existence of the P^* and S^* waves. He considered that the depth of focus was near 30 km. and that the thickness of the Granitic layer in this region was of the order of 40 km. Further, Conrad found a pulse which he thought was caused at the A. Mohorovičić discontinuity 60 km. deep under the earth's surface. It will be interesting to see whether or not these findings are confirmed by the present shock.

Inventors and Inventions

SIR JAMES SWINBURNE, in his presidential address delivered on October 25 to the Institute of Plastics, discussed the subject of invention. In his opinion, inventions are usually the work of men less than forty years of age and often are discovered by those without scientific training. He attributed this apparent anomaly to the likelihood of the technical man allowing his thoughts to be constrained in narrow grooves. The specialization of the modern world works against the interests of the home inventor. The day of the lone inventor has passed and progress is now usually the result of co-ordinated efforts of large research departments. Some of the greatest inventions have been, as a far-seeing judge once put it, what any fool might have done but had not. Differentiating between the independent or outside inventor and the inside or technical man, Sir James believes that the latter is the former's chief enemy. When the independent worker approaches a commercial concern with an invention he meets with opposition from the technical representative of the company, who is inspired by the human instinct of self-preservation, for the device submitted is something which the staff man feels that he himself ought to have thought of. A further distinction was drawn between the qualities necessary for an executive and those for a technical man Sir James epigrammatically stated that the object of patent law is to help industry by encouraging progress, by checking progress at each step , *in other words, if there were no patent law and* invention continued at its present rate, industry would progress faster , on the other hand if there were no rewards for invention, the incentive to invent would almost disappear In his opinion, the cost of patents is too high, and the legal expense entailed in fighting an infringement favours the large company The appeal system gives rise to anomalies Thus, the first judge may decide against a patentee, the appeal judges may agree with him, and finally three out of five in the Lords of Appeal might uphold the patentee s claim We then have the curious position of three judges overruling six

History of Iron Founding in England

At the annual general meeting of the Newcomen Society on November 9, Mr W A Young was elected president for the ensuing year The membership of the Society now stands at 870 After the conclusion of the business the first part of a paper by Mr Rhys Jenkins was read entitled "Iron founding in England 1490–1890 Though there are objects of cast iron to be seen in museums, probably made 1 500–2,000 years ago, iron founding in Europe as a regular trade is of comparatively modern origin In Great Britain iron founding followed the substitution of the primitive hearth, the bloomery, by the high furnace, known as the blast furnace Sussex was the cradle of English iron founding and there is a reference dated 1490 to a payment on behalf of the Archbishop of Canterbury to "ye Ierne founders of Buxstede' The industry was based mainly on the production of war material, though there was a certain amount of production of chimney backs, fire dogs and grave slabs, and also of gear for the forges King Henry VIII came to the throne in 1509 and he at once set about the provision of armament He brought over foreign workmen to cast bronze guns, and a year or two prior to his death the first cast iron guns were made The credit for initiating this departure belongs to William Levet, the parson of Buxted In the early days of Elizabeth, an export trade in cast iron guns commenced Guns were sent to the Low Countries, France and Germany, and in 1582 Portugal took no fewer than 132 pieces In 1601 it was stated the total output was about 800 tons per annum The earliest account of any real value of the methods of casting guns is given by Sirurey de Saint Remy in his "Memoires d'Artillerie" published in Paris in 1693

Structure and Strength

The seventh Andrew Laing Lecture, delivered by Sir William Bragg before the North East Coast Institution of Engineers and Shipbuilders at Newcastle on November 8, dealt with the molecular basis of the strength of materials Taking carbon compounds first, he showed how the regular arrangement of the carbon atoms in the diamond as determined by modern X-ray analysis accounts for its hardness, how long chains of such atoms with side atoms of hydrogen lead to paraffins, the tendency of which to set themselves parallel to each other like *corn stalks in a field leads to their slipperiness*, and how chains modified by oxygen atoms at one end lead to oils with lubricating powers Another arrangement of carbon atoms in a plane leads to graphite sheets, which again can slide over each other and also possess lubricating powers More complicated chain structures give celluloses of many kinds as found in plants, and a combination of benzene rings with oxygen gives plastics like bakelite The atoms of metals and alloys are in general packed together like spheres, and the properties of the product depend mainly on the sizes of the atoms constituting it and the number of electrons they can put into the common stock

The Science Museum Recent Acquisitions

The inventor s working model of the first calculating machine capable of multiplying sums of money in sterling currency (£ *s d* and fractions of a penny) has been presented to the Science Museum The present machine, invented by Mr E C McClure in 1934, requires only one turn of the handle for each digit in the multiplier, so that to multiply any sum of money by a number less than a thousand it is necessary to make only three turns of the handle The principles embodied in the machine are being used in a new sterling multiplying punch which is being manufactured by Messrs Powers Samas Accounting Machines Ltd , who have given the model to the Science Museum A collection of trade cards issued by English instrument makers to advertise their products, presented by Mr Thomas H Court, has recently been placed on exhibition , they are mostly of the eighteenth century and are of considerable historical interest and importance The Museum has acquired a large scale working model of the escapement employed about 1880 in the original Waterbury watches, which were among the first really cheap watches to be made The group of hearing aids illustrates developments since 1930 ; of special interest are the widely contrasting valve amplifying sets of 1932 and 1938

Radio Valve Data

Each year the *Wireless World* performs a very useful function in providing comprehensive details of all the thermionic valves available in Great Britain. The issue of November 10 contains a Valve Data Supplement listing more than 1,000 different valves in twenty pages of tables All types of valves are dealt with, whether these be used as rectifiers, frequency changers or amplifiers , and while some of those described may be becoming obsolete, it is necessary to include them as they are used for replacement purposes in existing radio sets or amplifiers In general, the valves are listed in order of filament or heater voltage, and the variation in this voltage is one of the reasons for the large number of valves it is necessary to describe Valves for battery operation have filaments for 2-volt working, while

4-volt types are used for A.C. mains operation; the 6·3- and 13-volt types are intended either for universal use on A.C. or D.C. mains, or for use with 6- and 12-volt motor-car batteries respectively. Fortunately, the number of valve bases is not yet equal to the number of valves, but fourteen different bases are listed, of which seven types are in common use in Great Britain, and the text explains that these seven may be connected up in 144 different ways. It is much to be regretted that those responsible for the design and manufacture of valves have not seen their way to bring about some measure of standardization; but in the chaos that exists, the valve data supplement referred to above should prove a useful guide.

Co-ordination of Medical Services

A DEPUTATION from the central emergency committee of the British Medical Association, including representatives of the Royal Colleges, was received on November 8 by Sir Thomas Inskip, the Minister for Co-ordination of Defence, who was accompanied by officers of the Government departments concerned. The deputation urged the establishment of machinery for the co-ordination of all medical services for the civilian population under a single body, and the co-ordination of civilian medical organizations under that of the Service Departments. It was also proposed that the machinery should be closely associated with the central emergency committee as being representative of all branches of the profession.

A New Chemical Periodical

A NEW periodical entitled *Chemical Products and the Chemical News*, which is being published monthly by Science Services, Ltd., 35 Great James Street, Bedford Row, London, W.C.2, is designed to emphasize the indivisibility of the chemical industry. It will accordingly deal with matters of interest to the chemical, drug, pharmaceutical and cosmetic industries, and particularly the new uses to which chemical products and related materials are being put and their future place in industry and in the framework of the modern world. In this policy, *Chemical Products* claims to be in the lineage of the *Chemical News* of Sir William Crookes. The first number (October) includes an article by Dr. F. R. Weidlein, director of the Mellon Institute, on industrial progress, in which developments in the fields of synthetic resins, lubricants and fuels, carbon black, plant stimulants, etc., in which that Institute has been concerned, are reviewed. In other articles A. L. Bacharach reviews the influence of laboratory on manufacturing technique, and C. W. D. Stafford describes the preparation and uses of liver extracts. Dr. W. Langer deals with the formulation of cosmetics, and Dr. C. I. B. Voge with that of mouth washes. An interesting account of the House of Roche is also included, together with the brief views of such eminent chemists as Prof. J. F. Thorpe, Dr. Joseph Needham and Dr. E. F. Armstrong on the nature, scope and policy of a chemical journal.

Colonial Service: Recent Appointments

THE following appointments have recently been made: F. J. Harper, agricultural officer, Nigeria; G. A. Jones, director of agriculture, Jamaica; F. H. Fitch, geologist, Malaya; I. G. Chamberlain, veterinary officer, Kenya; D. Slavin, veterinary research officer, Kenya; J. F. C. Swan, veterinary officer, Northern Rhodesia; D. M. Hanschell, assistant botanist, British West Indies Central Sugar Cane Breeding Station, Barbados; W. A. Hughes, inspector of plants and produce, Gold Coast; J. Sheard, sleeping sickness control officer, Nigeria; O. T. Faulkner (director of agriculture, Malaya), principal, Imperial College of Tropical Agriculture, Trinidad (seconded); J. D. Gillespie (agricultural superintendent, British Guiana), agricultural officer, Sierra Leone; B. J. Hartley (district agricultural officer, Tanganyika Territory), agricultural officer, Aden; J. F. Ward (agricultural officer, Nigeria), agricultural officer, British Honduras; A. Cawley (engineering geologist), inspector of mines, Tanganyika Territory.

Announcements

SIR WILLIAM BRAGG, president of the Royal Society, is to deliver an address on "The Advance of Science" at the Ely Diocesan Conference to be held at Cambridge on November 21.

DR. H. SPENCER JONES, Astronomer Royal, will deliver the fourteenth annual Norman Lockyer Lecture under the auspices of the British Association at the Goldsmiths' Hall, London, E.C.2, on Tuesday, December 6, at 4 p.m. The subject of the lecture will be "The Atmospheres of the Planets".

DR. HANS HOLFELDER, professor of general clinical roentgenology at Frankfort-on-Main, has been awarded the Albers-Schönberg Medal by the German Röntgen Society.

A SERIES of open meetings on "National Defence" has been arranged by the Scientists' Group of the Left Book Club, the meetings are being held at the University Labour Club, 101 Great Russell Street, London, W.C.1, on Mondays at 8.15. Among the topics and speakers are: aerial warfare, by F. W. Meredith; food supplies in war time, by F. Le Gros Clark; the medical services, by Dr. D. Stark Murray; and national defence and the scientific worker, by Prof. J. D. Bernal. Particulars can be obtained from the secretary of the Group, 175A Highbury New Park, London, N.5.

ACCORDING to a special health commission, Poland, which ought to have 25,000 medical practitioners, has only 12,000, there being about 3·7 per 10,000 inhabitants. 61 per cent are settled in 28 towns which contain only 13·5 per cent of the total population. In order to provide medical attention in rural districts a law is being prepared to compel every medical practitioner to practise in the country for his first two years.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return or to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 919.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

A Palæolithic Industry from the Cromer District

INVESTIGATIONS by us during the last four years, supported by grants from the Percy Sladen Memorial Fund, have shown that a hitherto unrecognized flint industry occurs in the coast section at Corton, near Lowestoft, and in the neighbourhood of Cromer.

From the geological point of view these particular implements occur in the marine sands at Corton which were classified by Searles Wood as 'Middle Glacial', and in the shelly sand and gravel in the Cromer coast section which was correlated by Clement Reid with these Corton Beds. They have not so far been found in the underlying glacial deposits at either locality, but the same flint industry is also found in certain unfossiliferous gravels which are exposed in inland sections near Cromer, and further work is needed to prove the relationship of these gravels to the marine sands.

We have made a collection of Mollusca from the shelly sand near Cromer, especially at West Runton Gap, and a comparison of these shells with those of the Corton Beds is satisfactory so far as it goes in showing that the West Runton fauna is more like that of the Corton Beds than that of any other known deposit. The shells show certain differences from those found in such older deposits as the Norwich and Weybourne Crags, and we are accordingly in agreement with the contentions of Searles Wood and Clement Reid that they are indigenous to the deposits in which they are found and not derived. The geological side of the work has also shown that there is no real discrepancy between the stratigraphical successions at Corton and Cromer respectively. Whereas the marine sands at Corton are intermediate between the 'Lower Glacial' deposits (of Searles Wood) and the Chalky Kimmeridgic Boulder Clay (of F. W. Harmer), those at Cromer are younger than the North Sea Drift (North Sea Glaciation of Solomon), and it has now been proved that marly boulder clay like that seen inland at Weybourne and elsewhere overlies the marine sands on the Cromer coast (near West Runton). At a pit a small distance inland at East Runton the implementiferous gravel rests on North Sea Drift and is covered in places by marly boulder clay.

It should be pointed out that as the marine horizon, together with its contained implements, underlies the Chalky Kimmeridgic Boulder Clay, it must be considerably older than and probably represents the interglacial period preceding, that in which the well-known Middle to Late Acheulean, and Clactonian III deposits of Hoxne, High Lodge, Whitlingham, and Derby Road, Ipswich, were laid down.

The flake industry found at Corton, and in the Cromer area, may perhaps be described as representing, in a primitive form, the later well-made Clactonian III implements of the High Lodge brick-earth. The Cortonian implements comprise side-scrapers (an outstanding form with the bulb of percussion at the side), hollow scrapers (very rare), square-ended scrapers and some small examples of the ordinary round-ended variety. Points are by no means common. The flakes exhibit flat striking platforms and have been in many cases modified by secondary flaking into knives and other forms. The great majority of the specimens exhibit a certain amount of gloss but are otherwise not patinated. The flint is black, usually with a thin cortex. The artefacts exhibit very little sign of rolling by water action, and scratches on the flaked surfaces are very seldom present.

It is possible that the industry represented may be of early Acheulean date, but with the exception of one specimen of a partly finished hand-axe the forms of the implements do not, in the present state of our knowledge, support this supposition. A detailed paper on this research will be published in due course.

Estimation of Uronic Anhydride Residues in Polysaccharides

IN the course of work on the constitution of certain wood starches and other polysaccharides containing uronic acid residues, we have found it necessary to investigate more closely the accuracy of the analytical methods used in the estimation of the uronic acid content. The usual procedure consists in heating the substance with aqueous hydrochloric acid and measuring the amount of carbon dioxide liberated.

Preliminary experiments revealed that potato starch gave an appreciable amount of carbon dioxide, and further investigation showed that the explanation of this lies in the fact that glucose and maltose give carbon dioxide under these conditions, the yield (c. 0·5 per cent) being similar to that observed with starch. It will be seen from the accompanying table that a similar yield of carbon dioxide is given by several types of starch and by cellulose, and the conclusion is reached that none of these polysaccharides contains any uronic acid residue. Fructose and fructose polysaccharides (for example, inulin) also give carbon dioxide when heated with hydrochloric acid, and, as might now be expected, so does sucrose. Rhamnose gave rather higher values, but a typical methylated sugar (2 : 3 : 6-trimethyl glucose) gave a smaller yield of carbon dioxide, presumably owing to the greater stability of the methyl ether groups, and mannitol, which cannot give rise to a reducing sugar, gave no carbon dioxide. In the case of glucose, fructose and sucrose, similar behaviour has recently been observed by H Colin and Mlle S Lemoyne[1]

PERCENTAGE OF CARBON DIOXIDE EVOLVED FROM CARBOHYDRATES

Substance	CO_2	Substance	CO_2
Potato Starch	0 30	Galactose	0 46
Rice Starch	0 45	Fructose	0
Wheat Starch	0 40	Inulin	0 60
Horse Chestnut Starch	0 50	Sucrose	0 52
Cellulose	0 17	Xylose	0 40
Glucose	0 40	Arabinose	0 4
Maltose	0 40	Rhamnose	0 90
2 3 6 Trimethyl glucose	0 20	Mannitol	0 00
Mannose	0 55		

It will be apparent that these results are of special importance in the investigation of polysaccharides In connexion with starches, no structural significance can be attached to reported carbon dioxide yields of the order 0 3 0 5 per cent, whilst for certain other polysaccharides, yields of carbon dioxide up to 1 per cent may be equally unreliable as an index of the presence of uronic anhydride These observations do not, however, affect the claim previously advanced by one of us[2] that certain wood starch preparations contain uronic anhydride, except in so far as the numerical value of the results is concerned The present experiments were carried out in an atmosphere of nitrogen in an improved form evolved by one of us (W G C), of the apparatus described by Dickson *et al*[3] With this consistent blanks were obtained corresponding to less than 0 2 per cent carbon dioxide under the conditions of the above analyses A scrubber containing aniline was used to absorb furfural liberated from pentose residues Otherwise furfural may be carried over to the barium hydroxide solution, with vitiation of the results

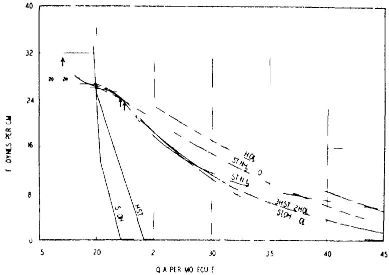
Effect of Space Isomerism on the Squeezing out of an Unsaturated Compound from a Mixed Monolayer on an Aqueous Sub-solution

As the pressure is increased on a mixed film produced by a 1 1 mixture of oleic acid (HOL) with stearyl alcohol (STOH) or amine, or stearic acid (HST), the unsaturated oleic acid begins to separate out at about 24 dynes per cm, at which pressure minute particles of the oleic acid become visible in the dark field microscope used for observation Practically all the oleic acid is squeezed out if the area is sufficiently reduced, and the pressure area relations become those found for a pure film of stearic acid or stearyl alcohol on the same sub solution (Fig 1)

While Schulman has indicated that this is probably due to a lessening of the attraction between the hydrocarbon chains by the presence of the double bond, earlier work by Harkins indicates that the double bond does not lessen this type of attraction It seemed to us that the phenomenon has its origin rather in the space relations The carboxyl or hydroxyl groups of all these compounds have about the same attractive energy toward the water of the subphase That it is the oleic acid which is squeezed out is apparently due to the fact that the bending of the chain by the double bond causes the molecule in its rotation about an axis perpendicular to the surface of the water, and in its vibrations and flagellations to sweep out a larger area than the saturated molecules This increased area causes it to be less firmly bound in the film



OLEIC ACID HOL STEARYL ALCOHOL STOH
STEARIC ACID HST STEARYL AMINE STNH$_2$

It is usually supposed that oleic is a *cis*, and elaidic acid is the corresponding *trans* form If this be true, it seems apparent that elaidic acid would sweep out a smaller molecular area and would be, therefore, much more tightly bound in the mixture This proved to be the fact, since while the ultramicroscope shows that some elaidic acid may be squeezed out the process is by no means complete as in the case of oleic acid In fact, the amount which separates is very small, since the form of the pressure area curves is not appreciably influenced thereby

The above relations were found on an acid sub solution, but a change to a basic subphase (pH 9 5), while it altered the form of the curves, gave similar relations, and this was also true when calcium ions were present

At pH 3 the presence of elaidic acid greatly condenses the expanded film of stearyl amine ($STNH_2$), while above a pressure of 8 dynes per cm oleic acid expands it even above the areas of the expanded amine By itself, however, elaidic acid as well as oleic, gives an expanded film At the lower pressures, oleic acid gives much the higher molecular areas when pure, but the smaller compressibility of the film of elaidic acid causes it to have higher areas at the higher pressures, that is, above about 15·5 dynes per cm. In the work represented by Fig. 1, the *p*H was 3, and the temperature close to 25°

Note added October 20 In a paper which appeared after our letter was sent to NATURE, Marsden and Rideal (*J Chem. Soc*, 1938, 1193) also explain differences in behaviour between *cis*- and *trans*-unsaturated compounds as due to differences in the form of the molecules Their theory of the effect is the more static, and ours the more kinetic

A comparison of the experimental results is of interest, since their most convincing evidence is given by two single-component films in which the area is much greater per molecule for the *cis*- than for the *trans*-compound Thus a 22-carbon atom molecule is long enough to give a sufficiently large van der Waals energy between *trans*-chains of brassidic acid to produce a condensed film, while with the corresponding *cis*-chain of erucic acid, the bend in the molecules prevents such a close approach so the film is expanded In the case of the 18 carbon atom chains used by us, the shortening of the chain reduces the van der Waals energy sufficiently to prevent the formation of a condensed film by the *trans*-compound, so the difference between the *cis*- and *trans*-compounds, while marked, is not so great

In contrast with this, the differences between *cis*- and *trans*-compounds given by their mixtures are very small, while some of those investigated by us exhibit extremely great effects. Thus in the mixtures on basic sub-solutions of stearyl amine with elaidic acid (*trans*) or oleic acid (*cis*), the isomeric forms not only give extremely great deviations from the mean behaviour, but also the *cis*-compound expands the area above that of either component, while the *trans*-compound condenses it below that of either component

Thus the two researches, when considered together, present remarkably strong evidence for the general point of view expressed by Marsden and Rideal and by us, that it is the bend in the hydrocarbon chain at the double bond of *cis*-compounds which causes them to be less firmly bound to the other molecules of the film than is the case with *trans*-compounds, in which the bend is much less pronounced

For the exhibition of these differences, space models should be used These make it obvious that the effects are highly dependent upon the position of the double bond in the chain

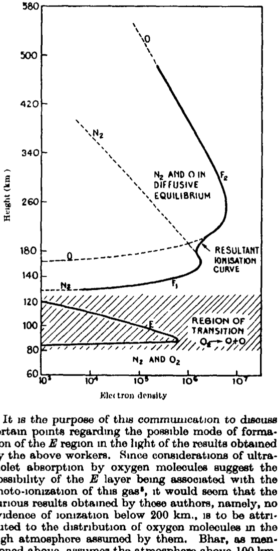
Origin of the *E* Layer of the Ionosphere

CHAPMAN's hypothesis regarding the different origins of the *F* and *E* regions of the ionosphere, first put forward in his Bakerian Lecture[1] of 1931, is well-known. The *F* layer he attributed to the action of the ultra-violet rays of the sun and the *E* layer to the action of neutral solar corpuscles. The reason for his assuming two different agencies was that he was unable to obtain any evidence of ionization maximum below 200 km. by applying Pannekoek's theory[2] of upper atmosphere ionization based on Woltjer's extension of Saha's theory of thermal ionization. The question of the possible mode of formation of ionization maxima in the upper atmosphere has recently been re-examined by Bhar[3] with the help of Pannekoek's method on the recent view that the atmosphere above 100 km has a high temperature and that it consists mainly of molecular nitrogen and atomic oxygen Bhar found that the only maxima of ionization are at levels 350 km (due to atomic oxygen) and 270 km. (due to molecular nitrogen) These he identified with the F_2 and F_1 regions He had not been able to obtain any evidence from his theoretical calculations about the presence of ionization at the level of the *E* region (100 km). Hulburt[4] has also come to a similar conclusion in a recent paper



It is the purpose of this communication to discuss certain points regarding the possible mode of formation of the *E* region in the light of the results obtained by the above workers. Since considerations of ultra-violet absorption by oxygen molecules suggest the possibility of the *E* layer being associated with the photo-ionization of this gas[5], it would seem that the curious results obtained by those authors, namely, no evidence of ionization below 200 km., is to be attributed to the distribution of oxygen molecules in the high atmosphere assumed by them. Bhar, as mentioned above, assumes the atmosphere above 100 km to be devoid of oxygen molecules—all of them having been converted to atomic oxygen by photo-electric dissociation. He therefore does not consider at all the ionization of molecular oxygen. Hulburt, though he assumes the presence of molecular oxygen (and molecular nitrogen) above 100 km., gets the result as stated above.

In view of the fact that recent investigations, both spectroscopic and theoretical, appear to show that the atmosphere above 100 km is very poor in molecular oxygen, Bhar's assumption seems to be correct. It may be shown[6] that the dissociation of O_2 to O is practically complete at about the 130 km level and that the region in which the transition of the atmospheric composition (from N_2 and O_2 to N_2 and O) occurs is a fairly sharp one. It is therefore evident that in investigating the upper atmospheric ionization the photo ionization of molecular oxygen in the transition region below 130 km should be taken into account, particularly because the ionization potential of O_2 (16.5 ev) being much different from those of O and N_2, this gas will produce its own level of maximum ionization. J N Bhar working in my laboratory has recently carried out the calculation of the photo ionization of O_2 after Pannekoek's theory in the region of transition of O_2 to O. The result obtained by him and the assumptions on which his calculations are based are given below.

The region of transition ($O_2 \rightarrow O + O$) is taken to lie between 80 km and 130 km. The density of molecular oxygen at the 80 km level is known to a fair degree of approximation from radio and other meteorological considerations. This is taken[7] as 1.6×10^{14} molecules/c c at 130 km the density is assumed to be 10^4 molecules/c c. Results of Bhar's calculations are depicted in the accompanying graph. For completeness the ionization distributions for the F_1 and F_2 regions as obtained by him from revised calculations are also given. It is to be noted that the maximum of ionization in the transition layer occurs at the level of the *E* region and that the ionized layer is extremely thin, which is in conformity with recent experimental evidence. The definite assertion can thus be made that the region around 100 km in which rapid transition of O_2 to O occurs is also as a consequence the region of maximum ionization of O_2, and that the ionized layer formed near this level is to be identified with the *E* layer.

For carrying out the above calculations a knowledge of the absorption coefficient of the gases under consideration is necessary. For atomic oxygen the value deduced recently by Saha and Rai[8] from wave mechanical considerations has been used. For molecular oxygen and nitrogen Bhar, in common with all previous workers, has utilized the well known Kramers formula for X ray absorption with certain modifications. The use of this formula for neutral atoms and particularly for neutral molecules is open to serious objection[4,5]. Crude as this procedure is, the importance of the analysis still remains for, if at any future date accurate experimental or theoretical values of the absorption coefficients and their variations with frequency be available, these need only be substituted in the working formula to get a more accurate result.

The origin of the *E* layer as explained above is due to strong absorption resulting in photo ionization of molecular oxygen commencing at λ 744 A. There is however, absorption due to nitrogen molecules and to oxygen atoms in this range of wave lengths. The effect of this absorption will be to reduce the intensity of the wave lengths necessary for the photo ionization of molecular oxygen. This fact has been taken into account by taking the intensity of the radiation in this range as one thousandth of what it would have been in the absence of the superincumbent gases.

A fuller and more detailed account of the investigation will shortly appear in the *Indian Journal of Physics*.

Effect of Temperature on the Intensity of X-Ray Reflection

WE have studied with a fibre camera used in conjunction and simultaneously with a flat plate powder camera the effect of temperature on the intensity of reflection of X rays from copper. The effect has been examined over a range of temperature extending from room temperature to about 570° C.

According to Debye's theory as modified by Waller in order to account for the decrease of X ray reflection from a cubic crystal as the temperature is raised the *intensities* of the interference maxima should be multiplied by a temperature factor exp $(-2M)$,

where $M = \dfrac{6h^2}{mk\Theta}\left(\dfrac{\varphi(x)}{x} + \dfrac{1}{4}\right)\dfrac{\sin^2\theta}{\lambda^2}$ *m* is the mass of the atom concerned, Θ is its characteristic temperature $x = \Theta/T$ where *T* is the absolute temperature and $\varphi(x)$ is a certain function of *x* which Debye evaluates.

Observations made on the intensities of reflection from rock salt and sylvine by James and his collaborators show that the results obtained with those materials agree fairly closely with Waller's modification for temperatures ranging from 85° A to 400° A but that for higher temperatures up to about 900° A there is a definite departure from the Debye Waller formula, the intensity falling off more rapidly with rise of temperature than is allowed for by the formula.

The present results obtained with copper which possesses face centred cubic structure show that *throughout* the range of temperature from 290° A to 840° A the decline of intensity with increase of temperature is greater than that predicted by the Debye Waller formula. The experimental results agree closely with the calculated results if the temperature factor is assumed to be exp $(-3M)$ instead of exp $(-2M)$.

A full account of the investigation will shortly be published.

A Lower Limit to Energy Evolution in Stellar Matter

IT is well recognized that the energy generation in stellar interiors is due to nuclear reactions in which protons play a dominant part. This circumstance fixes, as is shown here for stellar material of given density and chemical constitution, a lower limit to the rate of energy generation—the limiting value increasing very rapidly as the density of the material and the proportion of hydrogen in it increases. In the present note we shall only consider the reaction leading to the formation of deuteron by proton combination ($H + H = D + \varepsilon^{+}$), though the results discussed here can easily be extended to other nuclear transformations brought about by protons. The probability of this astrophysically important reaction has been recently calculated by Bethe and Critchfield[1], who conclude that for stars lighter than the sun this process is the main source of energy.

The existence of the lower limit mentioned above for the rate of energy generation follows at once when we note that the probability of the nuclear reaction is a function of the velocity of the protons, and as the protons obey Fermi-Dirac statistics, there exists for a given value of the proton concentration (number of protons per unit volume) a *minimum* energy distribution—the distribution corresponding to a *completely* degenerate gas. Therefore the limiting value of the energy generation for a given proton concentration n is obtained by averaging the probability of reaction for a velocity distribution corresponding to that of a *completely degenerate proton gas*; that is, the limiting value gives the energy generation when, for a fixed n, the temperature $T \rightarrow 0$.

If ε_0 denotes the minimum rate of energy generation per *gram* of the material, then, following Bethe and Critchfield with necessary alterations to take account of the new velocity distribution law, we finally obtain

$$\varepsilon_0 = 2\cdot4 \times 10^3 \rho c_H^2 e$$

where ρ is the density of the material, c_H the proportion of hydrogen by weight and z is given by

$$z = 4\pi^2 \binom{\pi}{3}^{1/3} \frac{m_H e^2}{h^2 n^{1/3}} = 4\cdot2 \times 10^3 \frac{1}{(\rho c_H)^{1/3}}$$

where m_H is the mass of the hydrogen atom, e the electron charge and h is Planck's constant.

In the following table the values of ε_0 are given for different densities for the case of $c_H = 1$ (all hydrogen) and $c_H = 0\cdot3$ (30 per cent hydrogen).

MINIMUM ENERGY EVOLUTION FOR DIFFERENT DENSITIES AND HYDROGEN CONCENTRATION

Density (gm/cm.^{3})	10^4	10^6	10	5×10^7
ε_0 for $c_H = 1$ (erg/gm sec.)	$1\cdot4 \times 10^{[illegible]}$	0·26	82	$1\cdot3 \times 10^6$
ε_0 for $c_H = 0\cdot3$ (erg/gm sec.)	$1\cdot2 \times 10^{[illegible]}$	$1\cdot3 \times 10$	$4\cdot9 \times 10^{4}$	$4\cdot3 \times 10^{5}$

It will be seen that ε_0 varies extremely rapidly with ρ and c_H. In the case of degenerate proton gas, the rate of energy generation for a given ρ and c_H will not differ much from the value corresponding to *complete* degeneracy, but for non-degeneracy it will obviously be widely different.

The existence of a lower limit to the rate of stellar energy evolution is particularly significant in connexion with the white dwarf stars (and also nuclei of planetary nebulæ). These applications, however, will be discussed elsewhere.

Seismic Methods in Submarine Geology

PROF. MAURICE EWING has shown that it is possible to use the seismic method for investigating submarine geology, and has used the method to show that in the continental shelf off the coast of Virginia many thousands of feet of sediments overlie the Palæozoic or pre-Cambrian rocks.

The Royal Society recently appointed a Committee with Rear-Admiral J. D. Edgell, hydrographer of the Navy, as chairman, to organize similar measurements on the eastern side of the Atlantic. The Lords Commissioners of the Admiralty made H.M. surveying ship *Jason* available for the purpose, and she was anchored successively at five stations on a line extending 170 miles west-south-west from the Lizard, and at each station geophones were lowered to the sea bottom. The geophones were connected to recording apparatus in the ship, and records were made of the ground motion produced by the explosion of charges of up to 62 lb. of T.N.T. laid on the sea floor and fired from a motor boat.

Forty-six records, mostly of satisfactory quality, were obtained, and time-distance curves were constructed. The first station was four miles south of the Lizard; the velocity of elastic waves in the surface rocks was 11,000 ft./sec.; this is too fast for recent sediments, but too slow for the igneous rocks of the Lizard. This surface layer was found to be 1,000 ft. thick and to be underlain by rocks in which the explosion wave travels with a velocity of 23,000 ft./sec.: the latter are presumably the igneous rocks. The occurrence of the 11,000 ft./sec. layer on top of the igneous rock is of considerable interest, and there is reason to believe from the results of dredging that it represents an outlier of Trias and indicates that the Channel was formed along the line of a pre-existing basin.

The next two stations are sixty and eighty miles west-south-west of the Lizard, and they showed 550 ft. and 1,000 ft. of sediments with a transmission velocity of 6,000–7,000 ft./sec. At the two outer stations (115 and 170 miles west-south-west of the Lizard), only lower limits can be set to the thickness of the sediments, as bad weather prevented very long lines from being shot. At the outermost of these stations the records are of excellent quality and show that there is certainly no rock having high transmission velocity similar to that found at the other three stations within 4,000 ft. of the surface. The next station shows that there are not less than 2,000 ft. of sediments.

It has been established, therefore, that a substantial part of the continental shelf is composed of relatively unconsolidated rocks. Measurements of the velocities of elastic waves in the rocks of Cornwall and Devon are to be made in the near future.

This preliminary note is published with the permission of the Royal Society In a later more detailed account, it will be possible to make proper acknowledgments to those who have assisted in the measurements and in the preliminary work

Oxygen Isotopic Exchange in Animal Respiration

Oxygen enriched with respect to ^{18}O has been used to solve the problem of how far oxygen expired by an animal in the form of carbon dioxide is identical with that inspired as molecular oxygen Using rats and an artificial atmosphere containing oxygen equivalent in isotopic composition to water of 300 p p m excess density it was found that the expired carbon dioxide which was dried and collected by refrigeration methods, contained oxygen isotopes in proportions corresponding to water with about 40 p p m excess density the error of measurement being 2 p p m As the quantity of oxygen absorbed by the animal during each preliminary sweep out was considerably greater than the total oxygen and carbon dioxide stored as oxy hæmoglobin or bicarbonate, it can be accepted that the experimental results refer to the steady state

The two possibilities usually considered with regard to the fate of respiratory oxygen are (1) it enters directly into carbon oxidation and is exhaled as carbon dioxide , (2) it enters into combination with the hydrogen of water the originally combined oxygen of which effects carbon oxidation and appears as carbon dioxide Our results show that mechanism (1) operates since (2) acting alone would lead to an almost complete absence of inspired oxygen from the expired carbon dioxide The fact that only a proportion of the inspired oxygen reappears may be due to oxygen exchange between water and carbon dioxide produced by mechanism (1) or it may be due to the incursion of mechanism (2)

Induced Tetraploidy in *Melandrium album*

In the flowering plants the problem of polyploidy in relation to diœcism is an extraordinarily attractive one, since it should be possible in this way to get additional proof of the balance theory of sex determination

So far, experimentally produced polyploids have not been described in diœcious plants, but occasionally such forms have been found in Nature In *Rumex*[1,2], triploids, tetraploids and a hexaploid have been described , in *Vallisneria*[3] and *Empetrum*[4] tetraploids are known to occur These polyploids which are considered by the authors to be of autopolyploid origin, are in *Rumex* intersexual in *Empetrum* bisexual and in *Vallisneria* diœcious, as in the diploid form

In *Melandrium album*, diœcism is very clear cut The male sex is heterogamous, having 11 pairs of autosomes and one pair of XY chromosomes, the X chromosome being considerably larger than the Y and larger than any of the autosomes The female plants are homogamous having 11 pairs of autosomes and 2 X chromosomes[5,6]

Tetraploids have been induced in *Melandrium album* in the summer of this year by the method of Randolph[7] as well as by the colchicine method[8] The tetraploid plants differ little from the diploids in appearance and are very difficult to pick out Their leaves are somewhat thicker the hairiness more conspicuous and the flowers relatively large Only chromosome counts can tell us the true nature of the suspected plants, and so far ten plants (out of 1 700) have proved to be tetraploid

These tetraploids are interesting from several points of view First concerning the sex expression The tetraploid plants show a diœcism just as clear cut as that of the diploids the $XXXX$ plants are females, the $XXYY$ plants are males (six of the ten tetraploids were males four were females) Secondly concerning the meiosis in tetraploid males a preliminary investigation has shown that the most frequent conjugation type of the sex chromosomes is autosyndesis that is $X—X$ and $Y—Y$ chromosomes pair Less frequently the sex chromosomes conjugate $X—Y$ and $X—Y$ The first mode of conjugation will give rise to gametes containing two sets of autosomes $(2A)$ an X and a Y chromosome $(2A+X+Y)$ The second mode will produce gametes of three sorts $(2A+2X)$ $(2A+X+Y)$ and $(2A+2Y)$ in the theoretical ratio 1 4 1, as previously postulated by H J Muller[9] A considerable excess of gametes of the formula $(2A+X+Y)$ will result As the females by normal chromosome separation will produce egg cells of the type $(2A+2X)$ only, three types of plants should appear by breeding tetraploids with tetraploids, if all types of gametes are viable the plants being of the formulæ $(4A+4X)$ $(4A+2X+2Y)$ and $(4A+3X+Y)$ It may further be mentioned that it is possible to cross tetraploids with diploids, both in the direction tetraploid female × diploid male, and the opposite way This should give rise to three types of triploids containing the chromosome sets $(3A+3X)$ $(3A+2X+Y)$ and $(3A+X+2Y)$ Thus the polyploid *Melandrium* should furnish very promising material for the study of sex balance

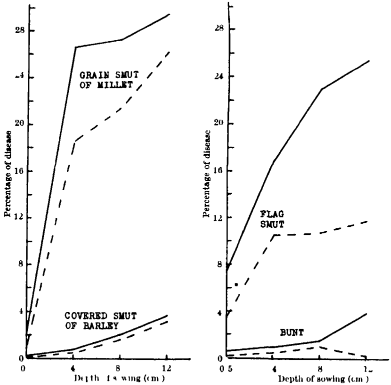
Control of Four Smut Diseases by Regulation of Planting Method under Irrigation

Anomalous amounts of disease in supposedly exactly repeated experiments of flag smut of wheat, and previously with covered smut of barley[1], were eventually traced to difference in planting method Under irrigation in Egypt, these cereals are either broadcast on moist land and ploughed in (*herati* method) or broadcast on dry land, harrowed in with a wooden baulk and irrigated (*afir* method)

Direct experiment proved two to three times more flag smut in *herati* plantings and similarly for covered smut of barley (six times), bunt of wheat (five times) and grain smut of millet Analysis indicates two factors operating, depth of sowing and soil moisture, shown in the accompanying graphs, where all differences are highly significant



Full lines, moist soil (*herati*)
Broken lines wet soil (*afir*)

Increase with depth has been recorded for flag smut[2], and again not only with covered smut but also with loose smut of barley[3], a flower infecting smut unlikely to be thus influenced , but perhaps this loose smut' was caused by the then unrecognized *Ustilago nigra*, a seedling infection

The cause of progressive increase may be the longer susceptible stage of deeper planted seedlings, while the strikingly small disease in the shallowest sowings may be due to coleoptiles growing more in air than damp soil The sudden effect in millet is perhaps related to the rapidly growing mesocotyl lifting the primary bud above the soil

The soil moisture factor is consistent and smaller, but increases with depth It is frequently mentioned in the literature (though few have worked with the very high soil moistures common under irrigation) and is usually ascribed to poor aeration The abnormally large effect in flag smut may be partly due to the peculiar germination needs of the spores[4] on the seed and in the soil, and hence partly dependent on the moisture history before sowing

While these results must generally remain only of scientific interest, they become immediately important in irrigation farming, where both operating factors are controllable The greatest inhibition of disease could be achieved if seed were broadcast on the surface of sodden soil, where fine particles allow soil moisture to reach the absolute maximum The results of two adjacent experiments with this new mud sowing' method are shown in the table below

Planting method	Cultural operations	Resultant depth of sowing	Soil condition	Per cent flag smut	
				Exp 1	Exp 2
Herati	Seed broadcast on moist soil and ploughed in	About 8 cm	Moist	8 1	8 6
Afir (usual)	Seed broadcast on dry soil harrowed in with a baulk and irrigated	4 cm	Wet		3 2
Afir (modified)	Seed broadcast on dry soil covered by raking and irrigated	2 5 cm	Wet	2 4	
Mud sowing (Method 1)	Moist soil ploughed and flooded seed broadcast on surface 1 hour later	Nil	Sodden	0 2	
Mud sowing (Method 2)	Dry soil flooded seed broadcast on surface 1 hour later	Nil	Sodden		0 08

Mud sowing seems worth thorough testing for agricultural value, apart from disease insurance It gives early tillering which may account for the improved size and maturity of grain obtained by Method 1 There is an indication of higher yield (although the elimination of 8 per cent of flag smut is unlikely to be the reason in Egypt) and seed rate might be reduced

Thus in irrigation countries special planting methods may present a practicable alternative to seed disinfection or immune varieties in preventing smut diseases

A full account of this and related subjects will be published as a *Scientific Bulletin* of the Egyptian Ministry of Agriculture

Bright Nebulosity in the 'Coalsack'

A PROGRAMME on the dark patch in the Milky Way, known as the 'Coalsack', taken when at the Boyden Station of the Harvard Observatory, Bloemfontein, included a number of red plates on that region. On one of these, a three-hour exposure taken with the Bruce telescope with an Eastman *I–C* Special plate and Ciné red filter, a small patch of bright nebulosity was observed within the region of the 'Coalsack'.

Dr Bok has confirmed for me the existence of this nebulosity on a long-exposure blue Bruce plate in the Harvard collection. There is no suspicion of nebulosity on two-hour exposure plates, but a six-hour exposure plate leaves no doubt of the reality of the nebula.

A detailed investigation will be published later.

Mechanism of the Primary Photodissociation Processes of Organic Molecules

IN his comments on our communication[1] under this title, Prof. R. G W Norrish[2] has raised certain questions which we naturally would like to answer. But as this discussion would certainly require more space than NATURE can devote to these questions, we prefer to deal with the matter in the detailed paper which is now in course of completion.

Points from Foregoing Letters

PALÆOLITHIC implements belonging to a hitherto unrecognized type, apparently of early Acheulean date, have been found by J Reid Moir and D F. W Baden-Powell near Cromer, in the marine sands at Corton, classified as 'Middle Glacial'. The implements are of black flint, usually with a thin cortex and mostly exhibiting a certain amount of gloss. Scrapers (side-, hollow-, square-ended and round-ended) and flakes modified by secondary flaking into knives, are among the implements found.

The liberation of small amounts of carbon dioxide from cellulose and from certain starches by aqueous hydrochloric acid has been shown by W G Campbell, Prof. E. L Hirst, and G T. Young to be due to decomposition of their constituent hexoses, and not to the presence of uronic anhydride residues. The yield of carbon dioxide from a number of typical carbohydrates is reported. Mannitol, which contains no potential aldehydic group, gives no carbon dioxide. These results do not vitiate the claim by W G Campbell that certain wood starch preparations contain uronic anhydride residues.

Prof W D. Harkins and R. T. Florence find that on compressing surface films containing oleic acid and stearic acid (or some other straight chain saturated compounds) the oleic acid separates out in the form of ultramicroscopic droplets due, the authors consider, to the fact that the bending of the chain at the double bond causes the molecule to require a greater surface and is consequently less firmly bound. Elaidic acid shows the phenomenon to a lesser extent and these findings together with those recently reported by Rideal and Marsden indicate also that the bend at the double bond causes the *cis*-compounds to be less firmly bound to the other molecules in the film than is the case with *trans*-compounds.

Prof. S. K Mitra discusses some of the new work on the ionization of the upper atmosphere and suggests that the *E* layer (80–120 km high) is a region of transition from molecular to atomic oxygen, and its ionization is due to photo-ionization of molecular oxygen by absorption commencing at a wave-length of 744 A.

The effect of temperature on the intensity of reflection of X-rays from copper (which possesses a face-centred cubic structure) shows, according to Prof E A Owen and R W Williams, that throughout the range 290–840° Abs., the decline in intensity with increase in temperature is greater than that predicted by the Debye-Waller formula.

Dr D S Kothari calculates the minimum energy evolved at different hydrogen concentrations by the combination of two protons to form a deuteron, which reaction is considered by Bethe and Critchfield to be the main source of energy for stars lighter than the sun. The minimum energy is obtained by averaging the probability of reaction for a velocity distribution corresponding to that of a completely degenerate proton gas.

Records of elastic ground waves produced by the explosion of charges of T N T laid on the sea-floor and fired from a motor-boat indicate, according to Dr E C Bullard and T F Gaskell, that off the coast of the Lizard a surface layer 1,000 ft thick, in which the velocity of the elastic waves is 11,000 ft /sec., is underlain by rocks (probably igneous) in which the velocity is 23,000 ft /sec.

Experiments by Dr J N E Day and P Sheel, in which rats were allowed to inspire oxygen containing the heavier isotope of mass eighteen and the expired carbon dioxide afterwards analysed for the heavier isotope, indicate that the inspired oxygen mainly enters directly into carbon oxidation and is exhaled as carbon dioxide.

M Westergaard reports that tetraploids induced in *Melandrium album* by the method of Randolph and by colchicine treatment differ little from diploid plants in appearance. They show the same clear-cut diœcism. The most frequent conjugation type of the sex chromosomes in tetraploid males is autosyndesis.

G Howard Jones and Seif el Nasr have discovered that the amount of four cereal smut diseases in Egypt differs greatly according to the method of planting. They have analysed this effect into a large factor of depth of sowing and a smaller factor of soil moisture. They have thence developed a 'mud sowing' method of sowing seed on the surface of soaked soil, which is practicable under irrigation, and almost eliminates disease.

Research Items

Skeletal Remains from Kansas Mounds

HUMAN skeletal remains with crania of a distinctive type have been discovered in mounds near Kansas City excavated by Dr. Walso R. Wedel of the Smithsonian Institution, Washington. In a preliminary report issued by the Institution, the skulls are described as distinguished by a ridge in the centre of the frontal bone, which must in life have given the people the appearance of having obliquely arched foreheads. The mounds in which these remains were found were low, never more than five feet high, each of them enclosing a partly subterranean rectangular stone chamber. Some of the remains had been cremated. The people were American Indians but possibly of considerable antiquity. These houses of the dead at one time had been numerous but a large number had been destroyed or looted within the last seventy five years, so that few were found in good order. To date eight complete or reconstructable skulls have been obtained. It is thought possible that the mounds are to be associated in some way with the Mound Builders of the Ohio Valley, the so called Hopewellians. In the suburbs of Kansas City, artefacts have been discovered, which unquestionably belong to the general Mound Builder complex, and representing the most westerly extension of that culture known at present. Although the long headed Kansas skulls might be related to the Mound Builders, no artefacts assignable to that culture have been found in the tombs. It is possible that the stone burial chambers may represent an early manifestation of the Hopewellian culture, or a variation adopted in a treeless region. The practice of the Hopewellians was to place their dead in a log house and when it was filled to set it on fire and pile earth over the ruins, making a mound about fifteen feet high. Sometimes two of these houses were set close together and eventually formed one mound. Owing to this practice of cremation, it is difficult to obtain a view of the physical type from such material as escaped the flames. Hence the peculiar physical type of the Kansas remains does not bar them from association with the Hopewell people.

Relation of Rare Defects to Population Changes

THE effects of inbreeding and isolation in a population on the frequency of occurrence of recessive or dominant characters due to single or multiple genes, is discussed by Dr. Gunnar Dahlberg (*Proc. Roy. Soc. Edinb.*, **58**, Part 2, No. 15). His conclusions are based on the statistics of cousin and other consanguineous marriages in Germany, France and Italy. He points out that any group within which marriages chiefly take place, owing to geographical or social barriers, can be regarded as an isolate in which amphimixis is occurring. Any particular recessive mutational genic defect will be unequally distributed in the population of a country, and the best way to decrease it is by decreasing the number of consanguineous marriages. But even the abolition of cousin marriages would only decrease the frequency of the carriers of rare genes by 10–15 per cent. Increasing the size of isolates, through increasing communications or through population growth, diminishes the number of recessives. In Prussia, first cousin marriages decreased from 0.71 per cent in 1875 to 0.20 per cent in 1926, so that the frequency of inbreeding is one third what it was fifty years ago, while the number of marriages has nearly doubled. In Bavaria the changes are still more marked, while in France the total number of marriages has remained nearly constant, as well as the frequency of cousin marriages, which remains at about one per cent. Movement from country to town increases the size of town isolates, while increasing intercommunication increases the size of country isolates. Both these effects will diminish the frequency of rare recessive defects. In Prussia and Bavaria where the size of the isolates has more than doubled in fifty years, the rare recessives will have decreased by at least one half.

Relation between Ovaries and Uterus during Pregnancy

THE golden hamster, *Cricetus auratus*, is a comparatively new laboratory animal, having been introduced from Syria in 1932. It is now fairly widely distributed, for it is easily reared and managed under laboratory conditions. The length of pregnancy is only sixteen days, which is shorter than that of other laboratory rodents. M. Klein (*Proc. Roy. Soc.*, B, June 1938) has investigated in it the relation between the ovaries and uterus during pregnancy. Ovariectomy between the ninth and thirteenth days brings pregnancy to an end. Injection of progesterone and œstrone simultaneously into the ovariectomized hamsters maintained pregnancy in some instances up to parturition. The duration of the corpus luteum of pseudopregnancy is noticeably shorter than in true pregnancy. Complete removal of the uterus between the eighth and thirteenth day of pregnancy results in the rapid regression of the corpora lutea and the initiation of the ovarian cycle. The removal, by Cæsarean section, of the fœtuses only, leaving the placentæ inserted, does not shorten the duration of the corpora lutea or remove the inhibition of the ovarian cycle. No interpretation of the mechanism connecting the uterus to the ovary is suggested.

Experiments on Hæmostasis

A. GRASSI (*Policlinico* (*Sez. Chr.*), **45**, 72; 1938) records his experiments on rabbits in which application of powdered bone to wounds of the liver had a remarkable hæmostatic effect, the hæmorrhage ceasing in 10–20 seconds. It was important that the powdered bone should have come from the same animal as that in which the liver was wounded, as the hæmostatic action of bone taken from another animal was much less. Grassi regards the hæmostasis as due mainly to a chemico biological action of the powdered bone and only in a very small degree to its mechanical action.

Parasites of the Elephant

TAKING advantage of his own examination of the internal parasites of four Indian and of several African elephants, O. P. van der Westhuysen has compiled a monograph of the helminth parasites of the two species (*Onderstepoort J. Vet. Sci. Anim. Industry*, **10**, 49; 1938). The parasites show a fairly strict host specificity, no species having yet been found to occur in both African and Indian elephants, although both possess an extensive nematode fauna Amongst the Strongylidæ, the African elephant has 25 parasitic species, the Indian 12, the Anchylostomidæ are represented by 3 species in the African, 4 in the Indian, the Syngamidæ has only one species —in the Indian elephant In all, ten nematode genera are represented in this fauna and of these, four are confined to the Indian species *Equinubria*, *Decrusia*, *Bathomostomum* and *Choniangium* All the Strongylids are parasitic in the alimentary tract except the members of the genus *Grammocephalus*, the adults of which inhabit the bile ducts The author gives descriptions of the species, keys for specific identification and many illustrations of distinguishing characters

Botanical Research in Brazil

The University of São Paulo Brazil, proposes to publish the work of the different departments of the faculty of science separately, all correspondence to be addressed Caixa Postal 2926 São Paulo, Brazil The first botanical publication, *Botanica*, No 1 1937, contains several interesting papers by Prof Felix Rawitscher on experiments upon factors controlling leaf symmetry and by his scientific assistant, Dr Karl Arens, upon the photosynthetic process Dr Arens also has a description of the different modes of entry of the germ tubes of *Bremia lactucae* The germ tubes of the conidia enter nearly always by piercing the leaf cuticle just above the position of an anticlinal wall, the zoospores settle down near a stoma and the germ tubes penetrate through the stomatal aperture

Features in Fern Prothalli

P N Mehra is mainly concerned with the occurrence of apogamy in the prothalli of *Adiantum lunulatum* and *Pteris biaurita* in two papers recently published (*Proc Indian Acad* Sci, 8, B No 3), but considerable interest is also attached to the very fine photographs he gives of the typical spirally thickened tracheids in the prothallus of *Adiantum* He describes these as of regular occurrence and a specific character of this gametophyte and a study of their development and detailed structure would have great interest as they would appear to be typically protoxylem elements though occurring in gametophyte tissue In this connexion it may, of course, have significance that they occur in a prothallial cushion on the anterior face of which may afterwards arise a fern sporophyte as a vegetative bud None the less, these tracheids are said to be typical of the normal prothallus—apart from the apogamous formation of vegetative buds, and they are also said to have no direct continuity usually with the vascular strands of such buds when they arise It is possibly also suggestive, in connexion with their presence, that Mr Mehra sees a tendency in these prothalli to continue vegetative growth, even after the production of a sporophyte has commenced The prothalli of *Adiantum* raised from spores from ferns from Sikkim showed no trace of archegonia, while others from spores collected at Kulu grown under the same conditions produced normal archegonia The prothalli of *Pteris biaurita* developed neither archegonia nor the usual prothallial cushion All these prothalli produced apogamous embryos, even in the Kulu prothalli of *Adiantum* the archegonia played no part in embryo formation

Leaf-Spot of Bananas

A bulletin of the Department of Science and Agriculture, Jamaica (No 15, New Series, Govt Printing Office, 1938) describes the leaf spot disease of bananas caused by *Cercospora musæ* Three types of infection are known and the spots pass from yellow to brownish black, having finally a grey centre The disease has a seasonal recurrence, being most severe in the rainy season when temperatures are low It occurs most seriously on compact alluvial soils, on soils of white limestone origin, and on the badly eroded soils of ridges Spasmodic, succulent growth favours the parasite more than the steady riper growth associated with the older banana lands, These conditions of external environment have a strong influence upon the incidence of the fungus but control can also be effected by spraying with Bordeaux mixture

Horticultural Uses of Peat

Diminishing supplies of stable manure have made gardeners acutely aware of the need for maintaining sufficient organic matter in their soils A very convenient source of humus is peat and Mr W J C Lawrence briefly describes the various kinds in a short paper in the *Gardeners Chronicle* of September 24 Wet peat can hold as much as 95 per cent of water, and is therefore useful for increasing the water holding capacity of light soils Rhododendron peat' usually has considerable quantities of silt and sand, and may have weed seeds in addition Moss peat and sedge peat are of uniform texture, and are free from weeds Mixtures of peat and artificial fertilizers provide adequate substitutes for farmyard manure, and peat is also useful as a constituent of rooting composts for cuttings It often has, in addition, a *p*H of about 3 5, and this would help the growth of many garden crops which require an acid medium

Soils of Dutch East Indies

In an article entitled Climate and Soil in the Netherlands Indies (*Bull Colonial Institute of Amsterdam*, 1, No 4), Dr F C J Mohr directs attention to certain factors that affect the soil and so the productivity of the various Dutch islands of the Malay Archipelago Rainfall differs much in some islands it falls on almost every day in the year, in others there is a marked dry season of greater or shorter duration Heavy rainfall causes leaching and impoverishment of the soil Hence it is the areas with a dry season that are most fertile Middle and East Java are more productive than Sumatra, in the same way that elsewhere in the world the civilized peoples of the tropics have always been in dry or comparatively dry regions The higher the altitude the lower the temperature This decreases the power of rain to leach the soil and so results in greater fertility at high elevations than on lowlands, always provided that first, the high elevation does not mean a greatly increased rainfall and, secondly, steep gradients do not facilitate active soil erosion Furthermore, higher elevations on account of lower temperature have more humus in the soil this enhances their fertility The one factor of great importance in restoring the fertility of the soil is the action of volcanoes that scatter ashes These, when basic, help to restore the value of the soil, hence again the greater fertility of Java than Sumatra and the poor soils of Borneo and New Guinea

Earthquakes in the Neighbourhood of Lake Michigan

THIS is an area where earthquakes are rare Since 1804 there have only been seven of greater intensity than 5 on the Rossi Forrel scale namely 1804 Chicago (6) 1883 Kalamazoo (8) 1909 Freeport (8), 1912 Aurora (6), 1928 Mt Carroll (5) 1934 Rock Island (6), and 1938 Porter (6) This last one has been studied by A R Schmitt, S J , of Loyola University Chicago, Illinois (*Earthquake Notes and Abstracts* 10 Nos 1 and 2 19 21) The earthquake was recorded on February 12 1938 shortly after midnight, by seismographs at the University of Chicago and at Loyola University but not at the next further stations at Ann Arbor Cincinnati and St Louis The *S–P* interval on the Wiechert record at Loyola was 9 seconds, the beginning of the *P* phase being at 6 h 27 m 41 s G M T whilst the Milne–Shaw at the University of Chicago registered *P* at 6 h 27 m 39 s G M T Joliat s tables thus give the epicentral distance from Loyola as 60 km or 38 miles In the absence of other instrumental evidence the area was canvassed for human evidence, and this was greatly assisted by the *Chicago Tribune* This established the presence of a sound concurrent with the shock which many thought to be double like a heavy truck passing the house , and also established the epicentral point as being in the lowland approximately fifteen miles to the east of Porter Indiana

Earthquake Sounds

ALTHOUGH it is usual for a rumbling sound to accompany most earthquakes this aspect of the shocks has not received a great deal of attention Dr C Davison (*Bull Seis Soc Amer* , 28, No 3, July 1938) helps to make good this deficiency by publishing the results of his large collection of observations chiefly from the British Isles He draws thirteen conclusions, the chief of which are (1) that the sound is a low rumbling one , (2) as the distance from the origin increases the sound becomes smoother and more monotonous (3) the intensity of the sound increases to a maximum with the strength of the shock and then dies away with it , (4) in British earthquakes, the sound area bears to the disturbed area a ratio that increases from an average of 54 per cent for earthquakes of intensity 8 to one of equality for earthquakes of intensity 4 , (5) the duration of the sound is usually greater than that of the shock

Copper Content of Sea Water

SINCE a number of marine organisms need comparatively large quantities of copper for their metabolism, for example, in the form of the blood pigment hæmocyanin it is interesting to determine the concentration of copper in sea water from which these organisms must derive their supplies In the expedition of the *Meteor* in the North Atlantic earlier this year, the copper content of water in the sub tropical North Atlantic (Sargasso Sea) was determined by a photometric method The results have recently been published by K Kalle and H Wattenberg (*Naturwiss* , 26, 630 , 1938) The concentration of copper obtained at ten different stations varied from less than 3γ per litre to 12γ per litre At greater depths, values up to 30γ per litre were obtained , but it is possible that these results were spoilt by impurities arising from the dredges, and they therefore represent maximum values The concentrations of copper found are too small to lend support to the theory that the colour of sea water is affected by its copper content

Steroidal Hormones

IN a paper summarizing thirty nine previous communications, R E Marker (*J Amer Chem Soc* 60 1725 , 1938) discusses the origin and interrelationship of the steroidal hormones from a general point of view The isolation and synthesis of sex hormones and the isolation of steroids from the adrenal cortex have led to an increasing realization of the important part played by steroids in the animal It seems to be generally assumed that these various steroids arise from cholesterol, but the author brings together several lines of evidence which make this seem improbable, and it is suggested that sex hormones and the cortical substance may be derived from another precursor The steroidal hormones, including the C 18, C 19 and C 21 sex hormones and the cortical steroids may come from a common precursor, pregnadione 4 8 diol 17,21 trione 3 11,20, or its hydrate at C–9 The bile acids are also supposed not to originate from cholesterol Consideration of the interrelationships among the many steroids make it possible to propose a definite structure for the precursor of the steroidal hormones and it is shown how the various steroids isolated may arise from this precursor by orderly processes following definite rules and, with few exceptions having their counterpart in laboratory reactions The paper gives a useful review of some of the literature bearing on its subject

Variability of the Sun s Radiation

AN important contribution to the study of the variability of the sun s radiation has recently appeared (*Quart J Roy Meteor Soc* , July 1938) It is an abstract of a thesis by Miss M M Paranjpe Improved methods of measuring the radiation received from the sun at the earth s surface have been developed by Abbot at the Astrophysical Observatory of the Smithsonian Institute during the last thirty years and with their aid very careful determinations of the solar radiation have been made on a number of mountains Mountains were chosen to facilitate the difficult task of allowing for the selective absorption of different wave lengths by the atmosphere before determining the solar constant Errors of observation, and of computation of this absorption, result in apparent variations of the solar constant from day to day , but real variations, if large enough, would be revealed by positive correlation between simultaneous determinations at different places Abbot has maintained that such variations have been established, and Clayton has attributed many variations of the weather to them But the critical examination of the evidence for the existence of any variation of the solar constant large enough to be detected even by the most up to date methods, which occupies most of Miss Paranjpe s paper, appears to show that Abbot's supposed variations are illusory If that is the case, none of the work based on them is valid It does not follow, however, that still more refined methods of observation in the future may not lead to the detection of very small variations, such as are to be expected in view of the known changes of the sun's appearance

Television

THE twenty-fifth Thomas Hawksley Lecture was delivered to the Institution of Mechanical Engineers on November 4 by Sir Noel Ashbridge, chief engineer to the British Broadcasting Corporation, the subject chosen being television. He began by pointing out that the scientific suggestions on which modern television is based were made at intervals extending over a period of more than fifty years. In 1873, a telegraph operator named May, almost accidentally, made the discovery that the value of selenium resistances varied according to the amount of light falling on them. This was confirmed by Willoughby Smith and Prof. W. G. Adams. The importance of this discovery lies in the fact that it provided for the first time a means whereby an electric current could be generated, the value of which varied in sympathy with the intensity of a beam of light.

The elementary telegraphy of pictures at rest presented no great difficulty, but television essentially includes the transmission and reproduction of moving objects which introduces considerable complication. In the first place, the exploring of the subject, element by element, by a beam of light—usually called scanning—must be carried out rapidly, and the process repeated a sufficient number of times per second to give the illusion of uninterrupted movement when the picture is reproduced at the receiving end.

A very important step in the development of practical television took the form of a scientific forecast—one of the most remarkable ever made. In 1908, A. A. Campbell Swinton wrote a letter to NATURE describing a device which he considered a scientific possibility; this was the forerunner of the now famous 'Emitron' tube. It was not developed until twenty-five years later. This special form of electron tube constitutes the essential feature of the system now used for generating the picture currents at the London Television Station. In Great Britain it was developed by Electric and Musical Industries Limited. In the United States a tube based on the same principle has been produced by the Radio Corporation, and in other countries similar devices are being developed.

In Great Britain, between 1923 and 1928 J. L. Baird developed a complete system of television based on scanning with 30 lines and transmitting pictures at the rate of 12½ per second. He generally employed a mirror wheel—a development of the Nipkow disk principle—at the receiving end of his apparatus, in conjunction with selenium cells, the light beam being produced by an electric arc. Although an experimental service was operated by the B.B.C. for many months, it was never developed successfully on a service basis. It is now replaced by the 'high definition' system which operates at the London Television Station.

Many difficulties had to be overcome in establishing the high definition system. It is well known that it is necessary to use a wave length of about eight metres. There was also the difficulty of establishing a definition standard which was likely to remain for a reasonable number of years without becoming obsolete. Thus it came about that in 1934 the Postmaster General appointed a committee, under the chairmanship of Lord Selsdon, to study the whole problem. The Selsdon Committee made four recommendations: first, that high definition television was sufficiently advanced to justify the establishment of a public broadcast service, and that the B.B.C. appeared to be the most suitable body to do this, in view of the possibility of its merging with sound broadcasting; secondly, that the two systems developed in Great Britain, namely, Baird Television Ltd. and the Marconi E.M.I. Television Co. Ltd., should each be given a practical trial; thirdly, that the definition standard should not be lower than 240 lines per picture and the number of picture repetitions not less than 25 per second; and lastly, that an advisory committee should be established for a period of about five years.

Thus it came about that a station was built to serve an area within a radius of about twenty-five miles from the centre of London, and equipped with two complete and different systems which were to be tried out under conditions which would allow of a comparative test of their respective merits. After some months of experience the Committee decided to continue the service using one system only and one standard of definition. This was put into effect on February 5, 1937, when the 405 line 50 interlaced frame standard was adopted. There is little doubt that should it become necessary in the future to increase greatly the degree of definition and therefore the range of frequencies to be transmitted, it will be necessary to use shorter wave lengths. At the television station, the channels adopted were 6.67 metres for vision, and 7.23 metres for sound.

It has been frequently stated that propagation could not exist beyond the horizon. It is now known that the effective range is not limited to a visual path. Regular reception is known to be possible at fifty miles, while good pictures have been obtained at a distance of two hundred miles. In considering the site of the station, the main requirements were that it should be within a few miles of the centre of London in order to give a strong service in the more densely populated areas, and that it should be on high ground relative to the London district in the broader sense. Taking everything into consideration, it was decided that the Alexandra Palace in the north of London, would be the best site. There are two separate aerials, for vision and sound respectively, but both are carried on a single mast which is itself mounted on one of the brick towers forming part of the Alexandra Palace. The maximum height of the mast above ground level is about 300 feet—giving a total height of 600 feet above sea level. The aerials themselves are therefore higher than the top of any building within a ten mile radius of Charing Cross. This is important when considering the possibilities of propagation using wave lengths of this type. When viewed from a distance, the mast and aerial relays are somewhat reminiscent of a lighthouse.

Public broadcasts of the Coronation, Armistice Service, the Derby, etc., have been very successful, and great improvements have been introduced by the new 'Super Emitron', the output of which is about ten times that of the ordinary emitron As to the future, the Television Committee has announced that the present standards will remain in operation for at least three years Any improvements during this time will not render existing receivers obsolete

There is one aspect of television development which must be recorded with regret At present there seems no likelihood of international standardization with regard to definition and picture frequency standards In the following countries the standards at the moment are as follows although there is as yet no public service

	Lines per picture	Pictures per sec	Modulation
America	441	30	Negative
Germany	441	35	Positive
France	455	35	Positive

In the distant future, international television cables may become available In this case the absence of a common standard in European countries will be a serious matter

In spite of these early difficulties there is no doubt that this new development of entertainment in the home will, in the course of time reach the same degree of importance that sound broadcasting has done , in fact it may be readily anticipated that the two services will ultimately merge

Localization in the Central Nervous System*

BY electrical stimulation of the brain, David Ferrier established the main facts relating to the localization of the motor centres in the cerebral cortex These facts have been confirmed on man as well as on animals, and have been of great practical as well as theoretical importance But although they have been the basis for all attempts to analyse the cerebral organization, they reveal mainly its receiving and executive apparatus and show little of the intervening processes

With the development of methods for recording the activity of the brain in terms of the electrical effects produced the problems of cerebral localization can be approached from another aspect It has been found that the cerebral cortex is naturally in a state of constant activity which may take the form of a rhythmic series of potential waves (for example, Berger's α rhythm) or of more complex and irregular oscillations When the activity has been reduced by an anæsthetic, the arrival of an afferent message has a twofold effect It produces a direct local excitation in the region in which it arrives and a more widespread increase in the persistent activity of this and neighbouring regions The latter result may be considered a local or regional awakening for it resembles the generalized increase in electrical activity which occurs in the brain when a sleeper is roused In either case a mutual reinforcement by cortex and thalamus is an important factor in raising and maintaining the level of the spontaneous activity

In certain cases electrical stimulation of the brain has the same facilitating effect as an afferent message The spread of activity can then be followed by making simultaneous records of the potential changes at different distances from the stimulated point and it can be shown how a number of competing wave systems can come into being

Electrical records have not yet revealed any features peculiar to the cerebral neurones In other parts of the nervous system there are many examples of rhythmic activity favoured by the arrival of impulses and in the cortex as elsewhere there are probably all grades of spontaneity, ranging from neurone systems which cannot help discharging periodically to those which need a specific stimulus for each reaction Thus the activity in a given region of the cerebrum will depend on the interactions of each, rhythmic and non rhythmic systems In normal conditions inhibition as well as facilitation will help to determine the local patterns of activity but in records from the narcotized brain the excitatory factors are the more prominent

* Abstract of the Ferrier Lecture of the Royal Society delivered by Prof E D Adrian F R S on November 10

International Cancer Research*

ACCOUNTS of the Second International Congress of Scientific and Social Campaign against Cancer which was held in Brussels in September 1936 have appeared previously in this journal (NATURE 138 727, 1936 139, 255, 1937) The second volume of publications of the Congress has now been published and contains accounts of some two hundred communications which were submitted to the Congress The General Minutes of the Congress are to form volume 3

The papers are divided into two main groups the scientific, and the social campaigns against cancer, and these groups are again divided into sub groups Among the papers on the social campaign are some interesting statistics of cancer in Germany, Poland Rumania, South Africa and the Dutch Indies It is possible to refer to only a few of the papers in this review , emphasis will be laid on foreign scientific work, as British cancer research is often reviewed in these columns

The first sub group of communications on carcinogenic agents deals with the action of cancer producing compounds, the nature of cancer viruses and the part played by hormones in the origin of cancer Drs J Maisin and Y Pourbaix describe how the production of cancer on the skin of mice by the active carcinogenic agent of tar, 3 4 benzpyrene, is inhibited by treating the animals with minute amounts

* IInd International Congress of Scientific and Social Campaign against Cancer 2 Communications Pp xii + 628 (Bruxelles Marcel Hayez 1937)

of the oxidation products of ether As yet the result has not been obtained with any pure compound

Dr N Waterman, of Amsterdam, describes how carcinogenic agents inhibit the breakdown of cholesterol esters and possibly cause increased esterification of cholesterol in animals The results indicate that agents which have a localized carcinogenic action may have a widespread effect in the animal It is possible, but not certain that general effects of this type may be an essential part of the carcinogenic action Prof F Vlès and Dr A Ugo show that if mice are injected with the fluorescent carcinogenic agent 3 4 benzpyrene, the hair becomes fluorescent and the spectrum resembles that of the original hydrocarbon Drs J G Chalmers and P R Peacock show that the same compound is excreted as a fluorescent derivative in the bile It is also excreted in some form in the urine and thus animals excrete carcinogenic compounds by three routes in skin fat, bile and urine but in most cases the compound produces tumours only at the site of application and not along the paths of excretion

Dr Albert Fischer, of Copenhagen reports on some *interesting transplantation experiments* Tissue from salivary glands, liver ovaries and mammary glands of young mice was grafted at a different site in the same animal from which the tissue was taken After 10 14 days, the graft was inserted in a fresh place in the mouse, and this was repeated several times In some cases the regrafted tissue developed into malignant tumours showing that normal tissue may become malignant either by selection or by change in the character of the cells

Among a number of papers on the *nature of tumour viruses* is one by Dr A Claude, of New York showing that the virus of the Rous sarcoma No 1 is destroyed by incubation with crystalline trypsin Crystalline carboxypolypeptidase had no action on the virus These results indicate that the Rous sarcoma agent is a protein Other experimenters have found that the agent is not completely deposited on centrifuging at 15 000 R P M but is completely deposited at 50,000 R P M

Several communications deal with inherited predisposition and resistance to cancer The results of Dr Maud Slye of Chicago, on mice breeding indicate that types of cancer segregate as unit characters, and the incidence of malignancy at different sites can be explained by laws of heredity Dr N Dobrovolskaia Zavadskaia introduced radon tubes into the groins of female mice which normally had a high incidence of mammary carcinoma The total incidence of cancer was not changed by such treatment, but one third of the tumours in the radon treated mice were sarcomata instead of the usual mammary carcinomata

One section of the volume deals with cancer diagnosis Prof P Lamarque of Montpellier shows photographs of tissues made by microradiography These are taken by placing a thin section of tissue on specially fine grained photographic film and exposing the tissue and film to feebly penetrating X rays Those parts of the tissue which contain heavy elements absorb the X rays and a photograph showing the distribution of heavy metals in the tissue is obtained The results are similar to those obtained by microincineration which shows the distribution of ash in tissues Historadiography however has the advantage that the tissue is not treated so drastically as in incineration It appears to the writer that a modification of this technique to determine the distribution of introduced radioactive elements such as radioactive phosphorus in tissues has possibilities

The Second International Cancer Congress was well organized and the volume of Reports' was published at the opening of the congress The volume of communications contains many papers of value, it is unfortunate that they could not have been published immediately after the Congress F B

Iron and Steel Works Developments

IN his presidential address to the Institution of Mechanical Engineers on October 21 Mr David E Roberts reviewed the changes which have taken place during the last fifty years in the basic industry of iron and steel making with which his experience has been primarily concerned The twenty five years preceding the Great War, when the world s annual output of steel increased from seven million to nearly seventy million tons, were marked by great activity in the development of improved processes of manufacture, and this period he regards as the one during which the greatest strides were made in the engineering side of the industry

Sir Lowthian Bell, president of the Institution in 1884, established the ideal height for blast furnaces and, even to day, few exceed 90 feet In other respects, marked changes have been made Hearths, from 11 ft diameter, have been doubled in size while blowing pressure has increased from 5 to 25 pounds per square inch to ensure that the air will penetrate to the centre of the wider hearths For blowing, Watt's beam engines with air cylinders 10 12 ft in diameter are now replaced in Great Britain by turbines while, on the Continent, gas engines are largely used Raw materials are much more carefully selected and graded and the result is easier working of the furnace, with a saving of fuel and an increased output Blast furnace gas now cleaned most thoroughly is actually cleaner than the normal atmosphere It is used for driving gas engines or, when mixed with the richer coke oven gas for heating and smelting operations In the Ruhr area with its very numerous blast furnaces and coke ovens the whole of the works are connected to a huge pipe grid and every cubic foot of gas generated is effectively used—there is no waste such as is sometimes seen in Great Britain Steel manufacture has also developed greatly The Bessemer converter has returned to favour for the production of commercial steel—on the Continent it has been practically the only method of making common steel The open hearth process is the British mainstay and these furnaces have increased from 20 to 100 tons capacity while some tilting furnaces of 250 tons capacity are in use Much mechanical equipment is installed in the melting shop to increase the speed of operation and to ease the labour and exertion involved in handling vast masses of molten metal

In the rolling shops the simple type of reversing mill has given place to massive machines rapid in operation and provided with lifting tables and other manipulating devices The absence of noise is remarkable when it is realized that at each reversal some 150 tons of machinery is brought to rest and re started An example of the adaptation of new materials to attain improved results is the use of fabric bearings to carry the heavy rolls One of the most recent developments is the rolling of sheets by what is known as a strip mill—composed of a continuous series of roll stands in tandem arrangement Twenty of these huge mills are in operation in the United States and one is being installed in this country The early attempts to roll sheets in a continuous mill were frustrated by the difficulty of ensuring that successive pairs of rolls were of exactly corresponding contour and consequent troubles with ripples ensued The Ashland plant in 1922 demonstrated the correct principles and the American strip mills are now stated to have an annual capacity of 12 to 13 million tons The graduation of the thickness of the sheet throughout such a mill is vitally important and automatic recording devices have to be employed so that variations can be shown on a much magnified scale

Science News a Century Ago

Education in the Metropolis

The Statistical Society on November 19, 1838, held its first meeting of the session, the first communication being the third report of the Society's Committee appointed to inquire into the state of education in the Metropolis This report contained a description of the schools in the parishes of St George, St James and St Anne, Westminster The area of these districts was 1,310 acres and the population according to the census of 1831, 110,862 It was estimated that there were 21,502 children between the ages of five and fifteen years, and of these less than one third received instruction in a school There were four kinds of private schools—dance schools common day schools, middle and superior schools—besides charity and infant schools The Committee had found the teaching imperfect, the surroundings often cheerless and there was a notable absence of a good supply of literature Inquiries had been made at some five hundred houses and the members of the Committee had been met with courtesy

Blasting by Electricity

At a meeting of the London Electrical Society on November 20, 1838, a paper was read by Martyn Roberts entitled On the Use of Galvanism in Blasting Rocks' A report of the paper appeared in Sturgeon's *Annals of Electricity*, 3, p 423 The author described experiments, which had been attended with perfect success, made on granite rocks in the neighbourhood of Penzance, Cornwall His method was to bore a hole 2 ft deep in the granite and place 3 in of gun powder in it A wad of oakum was then driven in 9 in from the top of the hole, leaving 12 in of air between the wad and the powder The upper part of the hole was filled with sand, a convenience being allowed for placing a thin iron wire in connexion with the powder, which wire became red hot, and consequently exploded the charge, when connected with the voltaic battery

Interior of the Earth

On November 22 1838, W Hopkins read a paper to the Royal Society entitled "On the State of the Interior of the Earth The object of the paper was to inquire into the modes in which the 'refrigeration' of the earth may have taken place, on the hypothesis that its entire mass was originally in a fluid state, a hypothesis which was at first founded on astronomical considerations and was corroborated by the discoveries of modern geology exhibiting the apparent injection from below of large masses of unstratified rocks through the fissures of sedimentary strata In the course of his discussion, Hopkins said that the internal mass of the earth may consist of matter still in a state of fusion, or the earth may consist of an external shell and a solid central nucleus with an intermediate stratum of matter in a state of fusion or the earth may be solid from surface to centre

The author of this paper William Hopkins, was born on February 2 1793, and died on October 13 1866 He began life as a farmer but at the age of twenty nine years entered Peterhouse Cambridge, and graduated as seventh Wrangler five years later Settling at Cambridge as a tutor he had among his pupils Stokes Kelvin Tait, Clerk Maxwell and Todhunter It was through Sedgwick that he acquired a taste for geology In 1850 he was awarded the Wollaston Medal for his application of mathematical physics to geology, and in the following year he served as president of the Geological Society In 1853 he was president of the British Association After his death the Cambridge Philosophical Society founded a *prize in his honour*

University Events

Cambridge—A L Percival, of Jesus College, and H G Rhoden, of St John's College, have been appointed University demonstrators in engineering and A M Barrett of Pembroke College, has been appointed University demonstrator in pathology

J R F Jeffreys, of Downing College, has been elected to an Isaac Newton studentship

The degree of Sc D has been conferred on F Yates, of St John's College

T P Hughes Rhondda research student, 1935–37, of Gonville and Caius College, has been elected into an unofficial Drosier fellowship for research in chemistry

The following new appointments have been made in connexion with the Cambridge Philosophical Society *Vice President* Prof F J M Stratton *New Members of the Council*, Dr E C Bullard, Dr L J Maskell and Dr F C Phillips

Sheffield—The following appointments have recently been made Dr G K T Conn, assistant lecturer in physics, W J Lytle, honorary lecturer in surgical pathology, Dr H E Harding, honorary lecturer in medical pathology, J Hughes, honorary demonstrator in anatomy, F G West Oram, at present junior research assistant, as assistant lecturer in glass technology

Universities and Citizenship

THE report of the 1938 congress of the National Union of Students held at University College Nottingham which recently appeared under the title The Challenge to the University (London National Union of Students) is a worthy successor to the admirable report on graduate employment issued last year While disclaiming any attempt at an authoritative statement it gives a stimulating picture of the way in which the problems of a university are being faced by the students themselves and of the extent to which the suggestions and ideas of the report of the University Grants Committee have permeated the student body

The report has indeed gained rather than lost in force through recent events which have focused attention upon the importance of a definite national policy in regard to man power and the most effective means of utilizing professional and technical workers in the national service in time of emergency Every approach to the problem of national defence emphasizes the importance of leadership whether we are considering the organization and utilization of national resources in a time of emergency or the wider question of national reconstruction along lines which permit freedom for development and individual activity in time of peace while providing the basis and framework of a defence policy adequate to meet the demands of any sudden emergency

Leaving on one side some of the fundamental problems with which the issues of peace and war must always confront a university in its pursuit of learning and the disinterested search for truth the problem of national defence poses problems of great magnitude to the university Indeed no plan or policy of national defence can be regarded as adequate which does not have regard to the position and contribution of the universities while safeguarding their highest ideals and traditions If a university is to participate actively in the task of national defence or preparation for defence it cannot be on terms which violate its independence of thought or its loyalty to the aim of furthering human welfare and knowledge

Two fundamental principles are urged in the report namely that the university should provide the means whereby its students can fit themselves adequately for an effective position in the vocational strata of society and that it should assist its students to develop powers of thought and interest in the affairs and problems of the modern world so that ultimately they may play a full and leading part in the life of the national and international community These are indeed indispensable from the point of view of national efficiency

The real problems arise indeed not from divergence of aim or principle but from the question of methods Methods which may best serve national efficiency from the point of view of national defence at least on a short view are not necessarily the best to safeguard the ideals or independence of the university or its teachers or students One of the difficulties of the times is the necessity of confronting the totalitarian regimes with their menace to independent and creative thought and man's richest spiritual heritage with a discipline and organization no less resolute or capable of sacrifices because it safeguards the freedom of thought and love of justice which are the mainsprings of man's finest achievements Upon the solution of this problem the future of mankind largely depends and no policy for defence which ignores it can enlist the enthusiasm and support which will safeguard and enrich the truths which democracy represents The democracies have to meet the challenge by proving themselves able to add to their own noblest tradition and heritage

This factor in itself should strengthen for example the appeal which appears even more clearly in the report in an address of Dr F Lincoln Ralphs for lecturers selected for the ability to inspire and expound rather than for their capacity for research The consideration of man power in relation to national defence throws into new relief the question of limiting the numbers of those who receive a university education and the importance of ability being the sole criterion for entrance to a university Again the point of view of national defence strengthens the case so ably argued in the report for greater attention to the physical well-being of students and attempts to raise their general standard of physique whether by measures designed to prevent illness or under nourishment the extension of medical examination further provision for the treatment of illness whether by the extension of health insurance or in other ways or by increased provision for physical training and exercise

It can scarcely be denied that in many of these respects the democracies have lagged behind the totalitarian States and if the necessity for an effective policy for national defence stimulates action to improve the situation while still safeguarding the independence and integrity of the universities the recent crisis may not have been without its gains Even from the point of view of national defence the broadening of university training is desirable to stimulate the growth of the virile citizenship upon which the continuance of democracy depends Any measure which checks excessive specialization encourages a knowledge of public affairs the ability to think clearly and critically not merely in abstract fields but also in regard to the complex affairs of human society and the power of disinterested thought in itself is a step to the provision of the wise and intelligent leadership needed

The report provides welcome evidence that the responsibilities of citizenship are recognized by a growing section of students themselves no less than of the university authorities and the consensus of opinion revealed encourages the hope that in Great Britain at least the demands of a defence policy upon the universities will be met without encroaching on their inherent freedom of thought investigation or teaching It should not be forgotten however that many of the measures outlined in the report for improving the present position turn essentially on finance Increase in staff extension of maintenance grants provision of new buildings libraries etc may all be required and the report stresses the need for an increase in the Treasury grants to the universities

Under the present conditions it is unlikely that such an increase can be looked for except as part of a comprehensive and long range view of the national resources such as is involved in the formulation of a definite policy of national defence covering the resources of man power no less than of material resources and in which the contribution and place of the universities are fully considered Any such review can scarcely fail to lead to increased provision for the care of student health and for physical training and other means designed to assist the student to take a fuller part not only in the communal life of the university itself but also in that of the community at large

If however the bearing of such aspects of student life on national service is more obvious the more fundamental contribution of the university should not be overlooked It is only as a democracy can provide the leadership which is not content merely to rest in the past but can make positive contributions to the solution of the problems of to day bringing to bear upon them constructive and creative minds which in courage resourcefulness and self discipline are at least the equal of any to be found in the totalitarian regimes that it can hope to survive In the long run it is on the universities which safeguard freedom of thought and investigation of learning and impartial criticism that democracy must rely both for the supply of leaders and for the vision and inspiration which will enable it to meet the greater demands of the present day

The significance of this contribution has been emphasized by the recent unhappy events in Germany The horror and revulsion with which the world regards the further persecution and suffering inflicted upon those of Jewish origin have brought also the realization how fragile are the barriers between us and relapse into barbarism Only wise and independent leadership alive to human values and capable of impartial and constructive criticism can save a nation be it under totalitarian or democratic government, from the many dangers which attend mass hysteria and propaganda

Mathematical Biology

Mathematical Biophysics

Physicomathematical Foundations of Biology By Nicolas Rashevsky Pp xviii + 340 (Chicago University of Chicago Press London Cambridge University Press 1938) 18s net

SOME ten years ago, Dr Nicolas Rashevsky then a young mathematical physicist turned his mind to biological problems and ever since he has been writing papers on the borderland between physics and biology too hard and too speculative for some but which others have read with great interest and attention

Dr Rashevsky has a way of his own He is neither observer nor experimenter His business is to reflect on what other men have seen or discovered to interpret it anew and to use the help which mathematical methods give to guide his thoughts and help his reasoning The physicist deals with atoms of extreme complexity but only yesterday thermodynamics were well and truly laid on molecules as simple as billiard balls The histologist keeps adding to our knowledge of the complex structure of the cell but Dr Rashevsky would have us meditate over an imaginary cell simplified almost out of all knowledge A first approximation based on so simplified or idealized a cell must be far from the whole truth but it may be a first step on the way to comprehension

We may simplify our cell as we like even reduce it to a little structureless sphere but it must still be a seat of chemical activity and change What leads to cell division in such a cell is the first question Dr Rashevsky asks The ratio of volume to surface increases as the cell grows and the due balance between them is lost thereby this is true and obviously true but what does it mean ? In its constant metabolism things enter the cell suffer change within it and pass out again diffusion goes on both without and within , diffusion currents are set up diffusion gradients are established and forces act proportionally to the gradients of osmotic pressure The cell is a seat of energy and a centre of force for the old phrase which Goodsir used nearly a hundred years ago turns up again with its meaning a little altered and better defined

In the simple, homogeneous spherical cell the resultant forces will be nil In a slightly deformed sphere absorption or diffusion inwards will tend to set it right but the diffusion outwards of substances formed within will tend to distort it the more and in certain circumstances these latter forces actually tend to split the cell They have against them the force of surface tension a powerful opponent so long as the cell is small there must be some critical size where the forces leading to deformation get the upper hand and disruption or cell division ensues On such lines as these but with the argument illustrated mathematically in ways that are always lengthy and often hard Dr Rashevsky discusses cell division and arrives at certain tentative quantitative solutions which turn out to be of the order of magnitude of ordinary cells He goes on to discuss some of the many cells which like a red blood corpuscle a *Euglena* or a *Paramecium* are very far from spherical but are yet able to maintain themselves in quasi equilibrium or a steady state so long as their metabolism continues and a given distribution of forces is maintained But we must not suppose nor does Dr Rashevsky attempt to persuade us that the road is easy or our course assured It is a difficult business all along and in an interesting appendix (to which Dr Gale Young's work contributes) the main discussion is somewhat simplified and is certainly improved Formidable difficulties remain The case of the slightly deformed cell is not difficult to understand but the successive stages culminating in division are hard to follow Then comes the further difficulty that no two cells are quite alike they have their little differences in outward form and greater differences in internal content and these differences would greatly affect our calculations if we did not neglect them one and all Yet life goes on just the same in all of them and the mode and rate of cell division seem insignificantly changed

Beginning with the dividing cell the first half of the book keeps in view as a far off aim nothing short of a physico mathematical theory of organic form the latter half passes on to physiological questions concerning nervous irritability excitation inhibition conduction and reflex action An interesting chapter (xvii) reprints a five year old paper of the author's* in which he explained nervous excitability on lines analogous to A V Hill's well known two factor theory but somewhat vaguely based on Jacques Loeb's work on the effect of relative concentrations of antagonistic ions He looks on the nerve as likewise containing two antagonistic substances the relative concentration of which leads at a certain point to excitation When a current passes along the axon, ionized substances flow one way or other and according as the inhibiting and exciting substances go to or fro and go the same or opposite ways various significant possibilities occur some of them such as have received experimental confirmation at A V Hill s hands

---

* Outline of a Physico Mathematical Theory of Excitation and Inhibition *Protoplasma* 20 42 56 (1933)

Dr Rashevsky starts afresh with the volley of impulses which Adrian finds set up in a nerve fibre with a vibrational frequency varying as the intensity of the stimulus When correlated with the same two factors in a diagrammatic system of neurones and synapses with a finite velocity in the one and a finite delay in the other many curious possibilities emerge A continual stimulus may lead to brief inhibition and lasting excitation or to just the converse a sudden stoppage of the inhibitory stimulus must in other circumstances lead to Sherrington s rebound phenomenon or something very like it and a certain particular distribution or pattern of peripheral stimuli will lead to a maximum or optimum stimulation at the centre But here and in all his other physiological chapters the weakness of the author s speculative method is more apparent than in his theories of the division of the cell. For a certain amount of pure speculation comes in handy and is even welcome in a case all but beyond the reach of experiment but nerve physiology is another story Sometimes the mere throwing of a phenomenon into mathematical form opens our eyes to something new as when Lotka and Volterra gave mathematical precision to vague instances of the struggle for existence But it oftener happens that mathematical symbolism leaves us just where we were before and merely expresses perfectly general relations where we had looked for something which should apply to and elucidate a specific case What Michel Petrovich called the *Mecanismes communs aux phénomènes disparates* illustrate over and over again the unimportance of mathematical analogy, and the need for something more than mathematical symbolism

We may admire Dr Rashevsky s learning and borrow ideas from his ingenuity but the physiologists will go on experimenting in their own old way Sir Charles Lyell said to the geologists Travel travel travel ! and the physiologists say to one another Experiment experiment experiment !

D ARCY W THOMPSON

The International Congress of Zoology

12e Congrès international de Zoologie tenu à Lisbonne du 15 au 21 Septembre 1935

Comptes Rendus Vol 1 Pp xix + 228 + 644 + 30 plates Vol 2 Pp 645 1514 + 41 plates Vol 3 Pp 1515 2424 + 28 plates (Lisboa Casa Portuguese 1936 1937) n p.

THE proceedings of the twelfth International Congress of Zoology which met at Lisbon in September 1935 have now been published in three handsome volumes which form part of the series Arquivos do Museu Bocage issued by the Zoological and Anthropological Section of the National Museum at Lisbon About two hundred papers communicated to the Congress are printed in full in the three volumes (each of nearly nine hundred pages) and they are illustrated by a hundred plates some of which are in colour in addition to many text figures The preparation and editing of this vast amount of material (in five languages) must have imposed a heavy burden on Prof A R Jorge the president and Prof F Frade the general secretary of the Congress and they are to be unreservedly congratulated on the result The printing and illustrations reach a very high standard and it is evident that neither trouble nor expense has been spared Those who had the good fortune to experience the lavish hospitality with which the Congress was entertained at Lisbon will be grateful to their Portuguese hosts for having provided such a worthy record of a memorable occasion

It is assuredly not to be laid to their charge if the general scientific interest of these volumes does not on the whole rise much above what one is accustomed to expect in the reports of international congresses There are some addresses especially among those delivered at the plenary sessions of the Congress handling major questions of biology which every zoologist will be glad to have upon his shelves Similarly in the more specialized proceedings of the various sections there are many papers which will appeal to a much wider audience than was able to hear them delivered at Lisbon Nevertheless it is evident that there are many who see in the proceedings of an international congress merely another vehicle for the publication of papers dealing with matters of detail and often of the most limited interest even to specialists One would have thought it self evident that descriptions of new species were entirely out of place in such a publication but there are several papers in these volumes that consist of little else Very little general discussion took place on the papers read and still less is here recorded in print

In the present state of world affairs any measures that facilitate intercourse and co operation between scientific men in different countries are deserving of the fullest support Among such measures the holding of periodical congresses is one of the most important and valuable, and those who undertake the heavy tasks of organizing and preparing for them deserve the gratitude of their colleagues It may seem ungracious to suggest adding to these tasks but there are certain reforms which if they could be carried out would add greatly to the interest and effectiveness of the meetings A group of the British delegates to Lisbon has already suggested to the permanent committee that future congresses might be made more profitable to those taking part if discussions could be arranged based upon papers which instead of being read at the meeting were printed and circulated to the members in advance This method has been adopted with success at certain international congresses of more limited scope and while there would be obvious difficulties in the case of so vast and diversified a field as that covered by zoology, it would be well worth while to try the experiment on a future occasion

One of the most successful attempts at international co operation organized by previous meetings of the Congress of Zoology has been the International Commission on Zoological Nomenclature If its decisions have not always received the unanimous assent of zoologists it has rendered an immense service by providing the only code of zoological rules that has any claim to international authority At Lisbon it was able to present a report recording considerable further advances towards a stable system of nomenclature One particularly hopeful step was the adoption of a long list of *nomina conservanda* in which changes that would have led to serious confusion are avoided by suspension of the rules in the individual cases Most unfortunately owing to causes that could not have been foreseen the Commission has been in a state of suspended animation since the Lisbon meeting It is to be hoped that it will be able to resume its beneficent labours before long W T C

Practical Genetics

(1) Handbuch der biologischen Arbeitsmethoden Herausgegeben von Prof Dr Emil Aberhalden Lief 466 Abt 9 Methoden zur Erforschung der Leistungen des tierischen Organismus Teil 3 Heft 7 (Schluss) Methoden der Vererbungsforschung Methoden zur Zuchtung von Drosophila von G A Lebedeff Methoden der Erforschung der Vererbungsvorgange bei Pflanzen von F G Brieger Methoden und Ergebnisse bei der Zuchtung von Tetriginæ von Robert K Nabours Pp 115–1402 + xiii (Berlin und Wien Urban und Schwarzenberg 1937) 17 gold marks

(2) Practical Plant Breeding
By W J C Lawrence Pp 155 (London George Allen and Unwin Ltd , 1937) 5*s* 6*d* net

IN a recent issue of NATURE (138 972 1936) there appeared a letter directing attention to the neglect of genetics by British universities The letter was received with the apathy characteristic of British biology where genetics is concerned No one denied the need for genetics in universities but only one correspondent supported it Meanwhile we have come to rely on the U S S R and the United States to lead the world in genetical research Although plant breeding has now become one of the foremost activities in the agriculture of the British Empire and despite the stimulus provided by such institutions as those at Edinburgh and at Merton, many universities offer no more than half a dozen lectures on primitive Mendelism under the title Evolution and Heredity and practical teaching in genetics is confined to three or four departments The four works which come under review in this notice should remove one of the last excuses for shirking practical classes in genetics

(1) Dr Lebedeff in the compass of 67 pages sets out clearly all the information one is likely to need for culture work with *Drosophila* rates of development at different temperatures data on fertility, technique for dealing with stock preparation of media and construction of thermostats methods of counting eye facets cytological technique (contributed by Dr Stern) and X ray analyses

Dr Brieger s contribution on methods in plant genetics covers a wide field He presents data on the size of populations required for estimating segregation with precision and on the technique of hybridization and there follows a synopsis of statistical methods The synopsis contains a number of useful tables but does not provide either theoretical treatment of the formulæ or practical examples on applications of genetics There is a section on the various kinds of Mendelian segregation and upon methods of calculating linkage and three pages on useful methods for making cytological preparations

Dr Nabours contribution on the grouse locust contains more results than methods It is a useful summary of the work on the genetics and cytology of Tetriginæ (Orthoptera) and includes details of X ray work on *Apotettix* on parthenogenesis and the inheritance of colour patterns

(2) Mr Lawrence modestly describes Practical Plant Breeding as a guide book for the enterprising gardener This function it will most certainly perform but it can be recommended to a wider public Chapters iv and v contain within fifty pages an account of Mendelism and the cytological basis of inheritance excellently suited for elementary students The chapters on the technique of hybridization and on methods of plant improvement are as appropriate for the enterprising university teacher as for the enterprising gardener Mr Lawrence s style is easy and clear The book and the technique it describes should be introduced into the botany departments of all universities still at the six lectures on evolution and heredity stage ERIC ASHBY

Bessel Functions

Bessel Functions
Part 1 Functions of Orders Zero and Unity (British Association for the Advancement of Science Mathematical Tables Vol 6) Prepared by the Committee for the Calculation of Mathematical Tables Pp xx+288 (Cambridge At the University Press 1937) 40s net

THE worthy completion of a long and arduous task will always draw from the beholder the tribute of an almost personal gratification Our sympathy and interest are at once enlisted by the opening sentences of Prof E H Neville s preface to the latest volume of the British Association mathematical tables Volume 6 a table of Bessel functions of orders zero and unity It is with the satisfaction of keeping a long anticipated engagement that a Committee of the British Association issues its first volume of tables of Bessel functions Half a century ago the Committee decided that the tabulation of Bessel functions was the most useful undertaking that it could promote Our sympathy is deepened when we read that Prof Alfred Lodge who had been one of the original Committee of 1889 and to whom this handsome volume is dedicated in terms of grateful affection died on the very eve of its publication

The tables appear to the reviewer to be as much above praise as they are beyond criticism In the course of a most valuable and interesting account of the constructing and multiple checking of the tables (an account which includes a list of errors discovered in pre existing tables of Bessel functions) Dr L J Comrie a member of the Committee states that in the reading of proofs not a single compositor s error was found in some 280 pages containing just under a million figures He expresses the belief that the tables are completely free from error and no one has a better right to be believed in such a matter

The tables are principally of the functions (to use the most accepted notation) $J_0(x)$ $J\ (x)$ $Y_0(x)$ $Y_1(x)$ $I_0(x)$ $I_1(x)$ $K_0(x)$ $K_1(x)$ of the last two multiplied by e^x and e^{-x} respectively and short tables of e^x and e^{-x} themselves In addition there are tables of the first 150 zeros of $J_0(x)$ and $J_1(x)$ with the value of the other of the two functions for each zero and a similar table of the first 50 zeros of $Y_0(x)$ and $Y_1(x)$ The most extensive tables occupying some 170 pages are those of $J_0(x)$ and $J_1(x)$ to ten decimal places from $x = 0$ by steps of 0 001 to $x = 16$ then by steps of 0 01 to $x = 25$ Those for $Y_0(x)$ and $Y_1(x)$ are from $x = 0$ by steps of 0 01 to $x = 25$ those for $I_0(x)$ and $I_1(x)$ are to eight decimal places from $x = 0$ by steps of 0 001 to $x = 5$ those of $K_0(x)$ and $K\ (x)$ are to ten places from $x = 0$ by steps of 0 01 to $x = 5$ the products of these by exponential functions carry the range to $x = 10$ then by steps of 0 1 to $x = 20$ Interspersed are pages of formulæ and recurrence relations asymptotic series and tables of auxiliary functions All tables are supplied with second central differences and the last four pages provide Everett and Bessel interpolation coefficients with a short description of how to use them

It is pleasant to read of the generous co operation of Prof K Hayashi who allowed the Committee to use his own published tables and of Prof H T Davis who provided the Committee with a 15 decimal manuscript table of his own and renounced publication of this in favour of the Committee

Nothing remains but to congratulate the Committee Table making is an art in which beauty and utility are interfused and indivisible This book more than maintains the high standard set by its predecessors in the series It is gratifying to learn that a second volume of Bessel functions of other integral orders is in an advanced state of preparation ' A C A

Statistical Year-Book of the World Power Conference

No 2 Data on Resources and Annual Statistics for 1934 and 1935 Edited with an Introduction and Explanatory Text, by Frederick Brown Pp 132 (London World Power Conference, 1937) 20*s* net

THIS Year Book represents a further stage in the attempt of the World Power Conference to compile international statistics of power resources, development and utilization upon a comprehensive and comparable basis As in the first publication (1936), definitions of each power type together with uniform tables were supplied to national committees and other organizations for their returns Ambiguities and minor defects discovered in these definitions during preparation of the first Year Book were rectified before circulation, and a corresponding improvement is reflected in this second volume

Admittedly a certain amount of additional data extracted from published sources could have been added, had they been expressed in similar units to those adopted by the World Power Conference to make the work even more complete , but throughout the volume the editor has followed a policy of including only those data which conform closely to the definitions adopted as standard for this work The statistics presented, therefore, may be regarded as accurate from the point of view of comparison with each other, though they are in no sense claimed to be comparable with other published statistics

Statistics relating to production and distribution of manufactured gas and to production stocks imports exports and consumption of coke are included in this volume for the first time Indeed, with the exception of wind and sun power, which the compilers state are the principal omissions practically every type of solid, liquid and gaseous fuel, together with water power and electricity has been dealt with

Animal Life in Fresh Water

a Guide to British Fresh water Invertebrates By Dr Helen Mellanby Pp viii+296 (London Methuen and Co , Ltd , 1938) 8*s* 6*d* net

IN recent years, partly as a result of the establishment of the Freshwater Biological Association's station on Lake Windermere, there has been in Great Britain a welcome revival of interest in the freshwater fauna and flora The ease with which many types can be obtained almost everywhere and kept alive in small aquaria makes them very suitable material for the school teaching of biology, and Mrs Mellanby's book has been planned to provide a guide for school teachers and pupils For this purpose it is in many ways well adapted

A large number of common invertebrate types are described and figured in sufficient detail to enable the elementary student to identify his captures approximately, and some account is given of the more important features of their habits and life histories It is much to be regretted, however, that a little more care has not been taken with its compilation Misspellings such as "ciliæ", "flagellæ', lacustræ', '*Chironomous*", "*Notamma*' (for *Notommata*) '*Chælonotus* (for *Chætonotus*) and the like occur on almost every page and will cause needless trouble to the student The style is sometimes slipshod, as, for example where it is said that the Spongilla fly (*Sisyra*) is not very common but this may be due to its being small and inconspicuous A sedentary animal attached to the body of another animal is by no means an epiphyte , and the colour of grey or brown specimens of *Hydra* is not due to zoochlorellæ

W T C

Modern Physics

a Second Course in College Physics By Prof G E M Jauncey Second Edition Pp xviii+602 (London Chapman and Hall Ltd 1937) 22*s* net

THAT Prof Jauncey's book, now appearing in a second edition has been reprinted three times since its first publication in 1932 is sufficient testimony to its usefulness The date of the first edition gives a hint of the principal additions to be expected and to be found in this new edition Besides these additions, which have involved much re arrangement and re writing chapters on wave motion, the new quantum theory and physics of high pressure have been added

For the information of new readers it should be stated that Prof Jauncey's book contains a fair measure of classical and introductory work including chapters on alternating currents the electromagnetic theory of radiation, gas kinetic theory, geophysics, and astrophysics, to mention five out of the twenty six chapters which go to make up the book One chapter deals with Some Useful Mathematics , and this chapter in view of the demands on the space allotted to the volume could be curtailed with advantage , the quite elementary calculus considerations are surely unnecessary to the type of student likely to benefit by the study of the book which, considered as a whole, is an admirable elementary introduction to the study of the problems of modern physics But Prof Jauncey should not describe Maxwell who was a distinguished exponent of the art of writing light verse, as given to writing verses of the jingle type '.

A F

A Text Book of Physics

By Dr D B Deodhar Pp x +672 (Allahabad The Indian Press, Ltd 1937) 6 rupees

DR DEODHAR has produced a useful text book of physics for students of intermediate grade The book covers rather more than the usual ground , the topics are discussed clearly and in some instances, a little more fully than is commonly the case There is a good selection of examples, and a welcome feature of the book is the number of succinct descriptions of applications of physical principles to technical instruments

The book bears signs of hurried writing—Foucault appears consistently as Focault, and there is a remarkable diagram showing the ascent of mercury in an open tube Mass is quantity of matter, Newton's law of cooling is treated as an approximation valid only for small temperature excesses, and the effect of temperature on the velocity of sound is given in the form $v = v_0 (1 + \frac{1}{2}\alpha t)$ It is more correct, twice as clear, and half as long, to show in a couple of lines that the velocity is proportional to the square root of the absolute temperature

These minor errors will doubtless be corrected in a second edition A F

Tropical Aquariums, Plants and Fishes

By A Laurence Wells Pp 160 (London and New York Frederick Warne and Co, Ltd, 1937) 3s 6d net

THIS is a very useful little book written in a popular style by an expert in keeping and rearing small tropical fishes Mr Wells has already published valuable guides dealing with similar subjects aquariums and fish ponds, and garden ponds, fish and fountains The present book will be welcomed by many, for the cult of the tiny tropical fish is rapidly increasing, and a sound practical book, simply written, is exactly what is needed, and this is what is offered With its aid there should be no difficulty in setting up aquaria and rearing the fishes The aquarium itself, heating, feeding, the best plants to use and how to deal with ailments, all have their share of space but half the book is taken up with short descriptions of the various fishes themselves, their distribution, habits, the prices which they fetch and information for the treatment of each species The book is illustrated by numerous small sketches, nearly every fish being figured and also the various plants recommended for living in the aquarium

It might be pointed out that in describing the food certain terms are used which are rather unusual for example, algæ as a singular noun and *Daphnæ* and *Enchytræ* as plurals

The Alloys of Iron and Chromium

Vol 1 Low Chromium Alloys By A B Kinzel and Walter Crafts (Alloys of Iron Research Monograph Series) Pp xv+535 (New York and London McGraw Hill Book Co, Inc, 1937) 36s

THIS volume is the first part of a review and summary of published information and available unpublished data on the alloys of iron and chromium containing less than 10 per cent of chromium The second part, now in preparation, will deal with higher chromium alloys, including the heat- and corrosion resisting steels The constitution of the iron – chromium and the iron – carbon – chromium systems and the effect of chromium on the critical point is first dealt with, these chapters being followed by surveys of the manufacture, treatment and properties of chromium steels and cast irons In preparing this monograph it is stated that nine thousand papers and articles were assembled; and that of these 478 were selected for detailed study. The latter group is given as a bibliography, arranged chronologically, and will prove a very valuable feature of the book A great wealth of data has been assembled in this volume, both in the text and in a large number of excellent tables and diagrams

Metallography

By Dr Cecil H Desch Fourth edition Pp viii+402+17 plates London, New York and Toronto Longmans, Green and Co, Ltd, 1937) 21s net

FOR twenty eight years Dr Cecil Desch's 'Metallography' has served admirably as a standard text book for students of physical metallurgy, and had previously run through three editions The last of these, however, goes back to 1922, and therefore a new and revised edition was considered desirable This has involved the re writing of most of the book as well as the introduction of new topics, among the latter are the improved technique of thermal analysis and of microscopic examination, the changes occurring in solid alloys (including age hardening and the order-disorder transformation) and the processes of mechanical deformation A section dealing with developments on the X ray side has been contributed by G D Preston

With the passing of time since this book was first published, it has become still more hopeless a task to compress into one volume our knowledge of physical metallurgy, but as an introduction and as a guide to the literature it continues to fulfil its function very well

An Introduction to Abnormal Psychology

By V E Fisher Revised edition Pp xiii+533 (New York The Macmillan Co 1937) 12s 6d net

THIS book appears in a thoroughly revised form The lapse of only a few years necessitates much revision in an exposition of such a subject as abnormal psychology But the author has done more than amend the first edition He has added seven new chapters and omitted three of the old ones doubled the number of illustrative cases, and otherwise introduced a good deal of fresh material

The book is essentially a text book, giving full directions for further reading, and aiming at a thoroughly comprehensive view of the whole subject At the same time, it is interestingly written, and merits the attention of the general reader as well as that of the student of psychology

The Basis of Tissue Evolution and Pathogenesis

By Dr Albert A Gray Pp xix+92+7 plates (Glasgow Jackson, Son and Co, 1937) 7s 6d net

IN this book, which is the posthumous work of an eminent Glasgow otologist, the author maintains that all tissues ultimately arise as the result of repair following injury, and supports his contention by examples of the labyrinth in animals taken from his work on the subject He points out that the term 'injury' does not mean merely gross mechanical injury but also includes the damage inflicted by chemical agents, poisons and physical conditions, such as moisture, heat, cold, etc He does not, however, exclude the possibility of chance variations or mutations having also played a part in the process of evolution

A short sketch of Dr Gray's life and work is given in the foreword by his son

Aspects of High Polymeric Chemistry

By Prof. H. Mark

INTRODUCTION

WHEN the magnificent structure known as organic chemistry was built up in the second half of last century, it contained not only an enormous number of new substances with interesting and valuable properties, but also embodied a series of more or less general laws on the relations between the structure and the qualities of a molecule It was realized, for example, that the presence of certain atomic groups (OH, NH_2, HSO_3) had as a consequence solubility in water, that other combinations of atoms impressed on the molecule the property of a dyestuff, others again made it a narcotic, or an explosive, and so on These laws did not appear suddenly in clear and definite shape, but grew slowly with the development of chemical science They were nearly all formulated at first as preliminary rules, and their validity checked by the aid of the continually increasing experimental material Some of them did not successfully pass this test , they are forgotten to-day and many of them are no longer known , others have survived and represent our present knowledge of the possibilities of constructing a molecule with required properties They can be called the leading principles of preparative organic chemistry, and are of utmost value for all synthetic work in chemical industry

At present, another organic chemistry is in full development– the chemistry of the high molecular substances Although they are built up of the same atoms as the normal organic molecules, namely, carbon, hydrogen, oxygen and nitrogen, and only occasionally contain other elements such as sulphur, chlorine, etc , they are of incomparably higher molecular weight While the single molecule of a normal organic substance such as benzene, urea or naphthalene has (referred to $O = 16$) a molecular weight of the order of magnitude of a hundred, the high polymeric bodies such as proteins, cellulose, rubber, polystyrene, polyvinylchloride, etc , achieve molecular weights of many thousands. At first they were found only in living bodies as frame-building substances and as resins ; to-day we know quite a series of chemical reactions, which enable us to build them up synthetically, and they appear to be growing in importance both scientifically and technically Almost daily a new polymerization product is built up and studied. In the chemical industry, we have to face already a host of commercial names, as neoprene, duprene, buna, perspex, victron, distrene, trolitul, mipolam, igelite, etc

In this state of affairs, while we naturally wish to produce an increasing number of these new bodies, it is also desirable to formulate some general laws on the relations between structure and properties, unless we are to lose all control over this rapidly growing branch of chemical science. When we look back to the development of organic chemistry, we cannot expect that these laws will be at once before us in their full clearness, but they will emerge slowly from the fog, which covers the yet unknown and mysterious region of our science Hence we are justified in putting forward some preliminary rules on the relationships between structure and properties, even although we are not yet in a position to give them the form of quantitative laws It must always be remembered that we have to test these working hypotheses very carefully against the experimental material, and that we must give them up at once if they do not work satisfactorily

SOME IMPORTANT VARIABLES

Our actual experimental knowledge on polymerization reactions enables us to state some characteristic features for a high-molecular sample, on which the final properties of the material depend in a very important way

(*a*) The *chemical nature* of the monomeric material ; it may be either aliphatic or aromatic , it may be a hydrocarbon, an ester a chloride or a ketone , it may contain one or more double bonds Table 1 gives a survey of the most important materials as regards their chemical nature

TABLE 1

CHEMICAL CHARACTER OF COMMONLY USED MONOMERIC MATERIALS

Chemical class of the monomer	Chemical formula of the monomer	Some trade names of the polymers
Hydrocarbons	Ethylene, $CH_2 = CH_2$	
	Butylene, C_4H_8	Oppanol
	Butadiene, C_4H_6	Buna
	Acetylene, C_2H_2	
	Styrol, $C_6H_5CHCH_2$	Victron, Trolitul
	Isoprene, C_5H_8	Natural rubber
Esters	Vinylacetate, $C_4H_6O_2$	Vinylite
	Acrylic ester C_4H_6O	Plexigum
	Methacrylic ester, $C_5H_{10}O_2$	Perspex
Chlorides	Vinylchloride, C_2H_3Cl	Igelite
	Dichlorethylene $C_2H_2Cl_2$	
Ketones	Methylvinyl ketone, C_4H_6O	
Alcohols	Vinyl alcohol C_2H_4O	Vinarol

(*b*) The (average) *length of the main valence chains*, which form the background of every high polymeric substance. It depends essentially on the way in which the sample has been produced; whether the polymerization was carried out at low or high temperature, with or without a catalyst and so on. Table 2 provides some idea of the numbers involved.

TABLE 2

DATA ON APPROXIMATE AVERAGE CHAIN LENGTHS

Material	Degree of polymerization, i.e., number of monomers in the chain
Natural rubber	approx 500-1000
Masticated rubber	,, 50- 200
Low polymerized styrene	,, 50- 100
Medium ,, ,,	,, 200- 800
High ,, ,,	,, 2000 5000

(*c*) The *internal flexibility* of the main valence chains. According to the fundamental ideas of stereochemistry and statistics of molecular movement, a very long hydrocarbon chain has a certain amount of internal mobility due to the principle of free rotation around the single main valence bonds. This mobility can be reduced by substituents, double bonds, ring formation, etc. Table 3 gives some examples of this property.

TABLE 3

DATA ON THE FLEXIBILITY OF THE CHAINS

Material	Internal flexibility of the chains
Cellulose	Very low
Cellulose esters	Very low
Polystyrene	Fairly low
Polyvinyl chloride	Fairly low
Methacrylic ester	Rather low
Acrylic ester	Medium
Polyvinyl alcohol	Medium
Polyisoprene	High
Polybutadiene	Very high
Polybutylene	Very high

(*d*) Main valence *linkages between the chains*. In certain cases, especially when the monomeric molecule contains more than one double bond, it is possible to create cross linkages between the long chains. This strengthens greatly the whole structure of the resin, makes it resistant to heat, impact and abrasion, but, on the other hand, increases the density and decreases the flowing properties. This 'netting' of the chains may be quantitatively characterized by the 'netting index' (*Vernetzungszahl*), which indicates the number of cross linkages to a hundred chain linkages. A netting number of 3 would mean that in the sample we have on an average three bonds perpendicular to the chains to a hundred parallel to them. Table 4 gives an idea of the amount of netting in different materials. It must be pointed out that, in accordance to the preliminary state of the whole of our quantitative knowledge in this field, all figures have to be taken as very rough estimations, but nevertheless they form a useful basis for further and better work.

TABLE 4

DATA ON CROSS LINKAGES BETWEEN THE CHAINS

Substance	Amount of cross linkages (netting index)
Native cellulose	Nearly zero
Native rubber	Nearly zero
Polybutylene	Very low, ~ 3-5
Polystyrene	Very low, ~ 3-5
Polyvinyl chloride	Very low, ~ 3-5
Soft rubber	Medium, ~ 5-10
Polybutadiene	Medium, ~ 5 10
Hard rubber	High, ~ 10-20
Buna	High, ~ 10-20
Bakelite	Very high, ~ 50

CONNEXION BETWEEN STRUCTURE AND PROPERTIES

After having enumerated some of the important factors, which together characterize in some way the structure of a high polymeric material, we may try to sketch some connexions between these factors and some of the more interesting technical qualities. For the present short survey, we choose the following properties: heat, oil- and water-resistance, impact and abrasive strength, electrical resistance and reversible elasticity. There are others, which may be equally important, for example, the flowing properties, the surface hardness or the dielectric constant, but it would be inappropriate here to deal with them all. For the sake of simplicity, it must suffice to state the results which one can derive from our present experimental knowledge together in a short table, without discussing every one of them in detail (Table 5).

At the top of the table, the different properties are named, and in the columns the four variables above-mentioned, namely: (*a*) chemical nature of the monomeric molecule, (*b*) length of the chains, (*c*) flexibility of the chains, (*d*) netting number. Two crosses mean that this particular variable has *no effect* on the special property at all, one cross indicates that it has *little effect*, if there is any effect it is stated in words.

We see, for example, that the impact strength is decreased by a small netting number and increased by a large netting number, that the water resistance is lowered by the content of OH and OCH_3 groups and made bigger by the introduction of CH_2 groups or fatty radicals, but that it is not affected by the chain length at all.

It is easy to see how such a survey can be used. Let us assume we want a material with high heat-, water- and electrical-resistance and great impact strength. Then we shall take a hydrocarbon with long chains (whether they are flexible or not is immaterial) and strong netting. If we want a rubber-like material, we have to make use of very long and flexible chains without too much netting. If it is to be oil-resistant we shall try to avoid

CH$_3$ groups in it, and we find that, as regards the flexibility and the netting number, the two qualities of oil resistance and high reversible elasticity require opposite factors Then it will depend on whether oil resistance or high elasticity is more important, and the choice will fall on a netting number in favour of the more valuable quality In the case of artificial rubber, for tyres, for example, the range of reversible elasticity must not be very high (about 100 per cent) but abrasive strength and oil resistance are so important that one would prefer a considerable amount of netting, as is indeed the case in all synthetic materials used for this special purpose, as neoprene, buna, sowprene or thiokol

It is easily realized how many possibilities for building up substances of very interesting properties are already available in such a rough and unexact scheme as Table 5 represents Nevertheless, it must be pointed out very clearly that it is absolutely necessary to work out every single case very carefully, and to weigh against each other all the required properties and possible results

At the present time, it is not possible to write down mathematical expressions for the relations between structure and properties of high polymeric substances, but it is possible to derive some preliminary and imperfect rules, which will help us to find our way in this new and very promising field of modern chemistry.

TABLE 5

RELATIONSHIP BETWEEN STRUCTURE AND PROPERTIES OF HIGH MOLECULAR POLYMERS

Heat resistance		Oil resistance		Water resistance		Impact strength		Abrasive strength		Reversible elasticity	
decreased	increased	decreased	increased	decreased	increased	decreased	increased	decreased	increased	decreased	increased
(a) ×	×	by CH$_3$, OCH$_3$, and fatty groups	by OH groups and O bridges	by OH, NH$_2$, OCH$_3$, HSO$_3$, COOH groups	by CH$_3$, C$_2$H$_5$ and fatty groups	×	×	by CH$_3$ or fatty groups	by OH groups	×	×

An African Survey*

THIS great survey of the problems of Africa south of the Sahara carried out by Lord Hailey originated in a suggestion made by General Smuts in his Rhodes Lecture at Oxford in 1929 when he pointed out that Africa was developing under the control of a number of European powers, that different, and often conflicting principles were being applied in the administrative, social, educational and legal fields, but that nowhere was there any survey of what was taking place in Africa as a whole His plea for a survey of the extent to which modern knowledge was being applied to African problems was met by the appointment of a committee consisting of Lord Lothian as chairman, Prof Henry Clay, Prof Reginald Coupland, Mr Lionel Curtis Sir Richard Gregory Prof Julian Huxley Mr Ivison Macadam Dr J H Oldham Sir John Orr and Sir Arthur Salter, with Miss Hilda Matheson as secretary The funds for the survey were chiefly provided by the Carnegie Trustees and later by the Rhodes Trust.

In 1933, Lord Hailey accepted an invitation to undertake the survey, but was unable to undertake personal work until 1935, though certain preliminary inquiries were set on foot in the meantime It was intended originally that the scope and form of the report—the conception of Lord Hailey—should be of a general character only, but as a result of a year's journey through Africa from the Cape to the Sahara, in which a distance of 22 000 miles was covered and information was sought and obtained from every possible source it became evident that the original conception must be much enlarged In the preparation of the report chapters dealing with special topics were prepared and the more important then circulated among the Colonial and other Governments concerned as well as among authorities working on these topics from whom additions and comments have been received

---

* An African Survey a Study of Problems arising in Africa south of the Sahara By Lord Hailey Issued by the Committee of the African Research Survey under the auspices of the Royal Institute of International Affairs Pp xxviii+1838 (London New York and Toronto Oxford University Press 1938) 21s net

The Committee believes in the words of Lord Lothian that this volume will mark a new era in the history of the continent—because it will enable those who are responsible for policy to consider it in the light of the problems of Africa south of the Sahara as a whole

The method of approach is objective and factual In addition to discussing the state of our knowledge of the problems of the development of Africa it describes the physical and social background out of which they have arisen and analyses the factors which must determine their solution Hence the early chapters of the report after introductory matter deal with the physical background survey and mapping climate and vegetation climatology and meteorology as well as the African peoples their divisions and institutions and languages and the agencies for their study at the same time pointing out deficiencies in method and scope

While Africa has a larger proportion of tropical area than any other continent from the human aspect its most striking feature is the fact that with the exception of Australia it has the lowest density of population in relation to its area The first of these facts has a special significance in relation to the extension of European settlement in Africa the second seems to be connected in some measure with the existence of known deficiencies in the constitution of the soil and with the prevalence of diseases facilitated by the malnutrition associated with such deficiencies This fact gives special importance to the necessity for a scientific approach by the African Governments to the interrelated problems of agriculture animal husbandry and health

A great number of areas in Africa still await topographical survey sufficient for the mapping needed for the handling of social problems and the work of material development It is however first necessary to supply an adequate geodetic framework on which a successful topographical survey must rest for the arc of the 30th meridian begun at the Cape early in the century on the advice of Sir David Gill has not yet been completed

In dealing with the study of the African peoples for purposes of description the conventional classification of Bantu Hamitic and Negro is adopted There is no anthropological survey which would make possible a classification of tribes on the basis of physical characters For present purposes however it is felt that a study of racial origins is of less importance than that of the reaction of African cultures to the influence of European civilization and that the social anthropologist can fulfil a practical function by providing material which will enable the African Governments in directing their own policy to see that the process of adjustment to new conditions shall cause as little disturbance as possible to African society Anthropological study has a further relevance in so far as observations made on African social life may be able to throw light on the existence of a characteristic African mentality The view here taken is that African social conceptions do not necessarily indicate any intrinsic difference of character or mental capacity between them and other peoples Neither the examination of the brains of Africans as indicative of mental capacity nor intelligence tests have as yet furnished any conclusion which will assist in the determination of general administrative policy

The diversity of native languages taken as seven hundred in number constitutes a problem of special difficulty particularly when policy has determined that education shall be given in the vernacular It is necessary in such cases to determine whether the language chosen shall be a dominant vernacular or a lingua franca such as Swahili It is a question whether either the African Governments or commercial firms attach sufficient importance to the attainment of linguistic efficiency by their servants

Great differences exist as between estimates of the indigenous population of Africa Expert authority now limits itself to the view that the present total may lie between 138 100 000 and 163 300 000—in itself it is remarked commentary on the value to be attached to the present system of enumeration It is thought probable that the African population is either stationary or subject to a very slow increase The desirability of a more efficient system of enumeration is shown by the difficulty of checking many current assumptions on such matters as the extent of infantile mortality and the effect on the birth rate of African marriage customs A system of registration of births and deaths might be introduced in all areas where there are means of securing reasonable accuracy

Having dealt with natural conditions and the people the report then turns to their relations with and position under European authority

In the matter of policy the presence of a considerable European element in some of the British territories gives rise to consideration whether the prevailing policy of indirect rule is compatible with the ideal of self government by representative institutions and whether native institutions must not be materially modified if they are to be made to fit into any scheme involving an elected parliament The objective of South Africa and Southern Rhodesia—the preservation of the social and economic standards of European civilization—leads to the policy of segregation in which in the Union access is provided to a consultative body the Natives Representative Council and not the South African Parliament French policy does not envisage a future self government but development which will fit a colony to occupy in reality the position now assigned to it in principle as an integral part of France Emphasis is not on securing a growing measure of political rights but on progressive access to French culture and legal institutions The main source of legislation is the ministerial decree and executive devolution a concession to the influence of personality rather than to principle In the Belgian colonies the policy of material development is combined with a conscientious recognition of the need for safeguarding the conditions of labour promoting health organization and improving the means of subsistence

Careful consideration is given to the question of labour The normal economic incentive is now an influence of increasing strength Labour problems are due to shortage of the local supply rather than a disinclination to enter wage employment

In relation to the land the communal system of landlord holding prevails over the greater part of Africa and it would be premature to give legal recognition to individual titles but it may be necessary before long to undertake this process in economically advanced areas

In the use of the land at an earlier stage in the history of the agricultural departments attention was largely directed to finding means for increasing the production of export crops Of late years a variety of causes has tended to emphasize the need for improvement of native subsistence crops Native agriculture is for the most part based on the system of shifting cultivation a natural adjustment to the needs of African soils which require a considerable period for regeneration after cropping The settlement of population in fixed areas and pressure on the soil due to the expansion of economic crops have led to the use of the system in an abnormal manner with the result that the period of regeneration is unduly curtailed and the vegetal cover destroyed As regards animal husbandry the salient facts are that over a large part of Africa the tsetse fly makes it impossible to keep domestic cattle and in other large areas the semi religious value attached to cattle leads to overstocking which is liable to cause great destruction of pasture and to produce soil erosion

The first effort towards the improvement of native agriculture must be to indicate an alternative method for the regeneration of soil after cropping of which one of the most promising examined appears to be mixed farming Its success however will depend upon the efforts made to secure protection from the tsetse fly and to secure a more economic use of cattle by the natives elsewhere Although native methods of agriculture are rooted in custom past experience shows that new methods will be accepted if these can be demonstrated to be adapted to their circumstances Every effort should also be made to secure the co operation of the Africans themselves in the preservation of their woodlands It is clear that erosion a major problem in so far as it is caused by shifting cultivation and by overstocking has been accelerated by modern conditions under which populations are concentrated, more extensive areas of land are cultivated and the increase of stock is more rapid

Problems of health are obviously of much importance but there are no reliable statistics which would enable a comparison to be made between Africa and other territories in respect of the prevalence of disease The fact remains however that malnutrition is a characteristic feature of many parts of Africa there are low standards of hygiene in many rural areas and in most urban native locations and there is a marked prevalence of malaria sleeping sickness venereal disease and different forms of helminthic disorders The task of the health services in Africa extends beyond the application of modern scientific technique for the prevention and cure of disease they share in the responsibility for other social services for the improvement of African conditions of life Their part is the more important because they are concerned with some of the fundamental problems of Africa such as that of nutrition

Only of recent years has systematic thought been given to the form which native education should take in Africa At an earlier stage in the Union official opinion would have given to the African only the instruction suitable for those whose future lay in subordinate positions in European employment A change came with the recognition by the Governments that education must be extended progressively throughout the population As a result the educational system in the Union is now coming under revision Current policy seems to indicate the vernacular as the most suitable medium for popular education both in the Union and in the British Colonies, where an effort is being made to give school courses a content suitable to African environment But native education is still in its initial stages and the wider employment of Africans in the public services is delayed owing to the lack of candidates fit to receive special training for their work The most pressing need in regard to popular education in British territories appears to be better means of control and improved standards of teaching The future of advanced education must remain in some doubt until the Government arrives at some definite policy on the position which the native is to occupy in the administrative and technical departments particularly under a system of indirect rule In the French possessions education forms an essential feature in the policy of association A carefully devised system separates the *élite* from the mass giving the former a training which engages their sympathy with French culture and makes them efficient auxiliaries in the work of administration The chief characteristic of the Belgian system is its effort to improve the African s capacity for the work of developing the Congo

In discussing the internal and external aspects of economic development the report has much interesting material for consideration and makes the pregnant deduction from current tendencies that in the future the European may move away from general agriculture into commerce or various forms of non agricultural enterprise

On the other hand the future economic prosperity of some of these countries probably depends more upon the general development of native economic activity than on the results of European enterprise The African however cannot achieve his economic development without a material change in his present social customs

We see before us now the most formative period of African history Much that is done to day will have a decisive effect on the future of the African peoples The task of guiding the material and social development of Africa gives rise to problems which cannot be solved by the application of routine knowledge they require a special knowledge which can only be gained by an intensive study of the unusual conditions This study must be pursued in the field of the social as well as the physical sciences For this purpose assistance is required from the Imperial Government This should take the form of a grant to be administered either by a Committee of the Privy Council or by the Economic Advisory Council Further the difficulty which is now felt in readily securing information about Africa should be met by the establishment of an African Bureau covering social economic scientific and administrative problems which will constitute both a clearing house for information and a source of assistance to aid all those who are pursuing research or inquiry into African questions

Czechoslovakia's Contributions to Science A Survey and a Forecast

By Dr Gerald Druce

WHEN the Czechoslovak State regained its independence in 1918 the people looked forward to a period of fruitful constructive effort in industry education culture and science Despite a long period of subjugation the nation could look back upon a tradition in the field of science and learning The University of Prague the oldest in Central Europe was founded in 1348 and during the Middle Ages the natural sciences flourished in Bohemia as is shown by the number of herbals and contemporary mineralogical and alchemical works in the Czech language

With the defeat in 1620 of Frederick the elected king of Bohemia and son in law of the English monarch Bohemia not only lost its independence but also an end was put to all cultural and scientific activities for more than a century Practically all Czech publications had then to be printed in Poland Holland and certain German States The University was handed over to the Jesuits who combined it with their college which had existed since 1556 It was re named the Charles Ferdinand University German gradually displaced Latin as the language of instruction Science was scarcely taught and although Adam Zalužansky in 1604 had insisted that botany for example should be considered a separate subject what courses there were covered all the sciences Among the few distinguished professors was Jan Bohac (Bohadsch) but even his comprehensive Flora fauna et historia regni lapidei Bohemiae remained in manuscript When he died in 1768 the science chair remained vacant until 1775 when his pupil Zauschner (who re discovered the *Gagea Bohemica* described by Jan Cerny in the fifteenth century), gave some lectures on natural history His successor was J G Mikan, a medical man who lectured mainly on chemistry

A cultural revival first became possible towards the beginning of the nineteenth century, when certain noblemen with a feeling of local patriotism became patrons of science Thus, through the efforts of Count Ignatius Born the Bohemian Scientific Society was founded in 1775 This society interested itself primarily in the study of local flora fauna and minerals but later turned its attention also to mathematics, astronomy and physics Count Malabaila Canal a foreign resident in Prague laid out a garden for the cultivation of economic plants and founded an institute for lectures in botany to be delivered by distinguished Czech botanists These were given for more than thirty years, but ceased when Count Canal died in 1826

Science found its strongest supporter, however in Count Kaspar Sternberg the centenary of whose death falls this year He was himself a botanist and palæontologist and the author of many scientific works , but his greatest achievement was the founding of the Bohemian National Museum in 1818 To this he not only presented his own extensive collections but also he impoverished himself to purchase books, minerals and herbaria from others, especially Czech collectors whose expeditions abroad he sometimes financed He also liberally supported the scientific periodical *Krok*, which appeared between 1820 and 1840 under the editorship of J S Presl, who published in Czech much contemporary scientific work

The National Museum was important because it developed an interest in science, though after Sternberg s death it widened its scope to become the rallying point of all Czech culture Nevertheless, this was a period when Bohemia possessed a number of famous biologists such as the brothers Presl A J Corda and F M Opiz, all of whom made contributions to the advancement of botany, whilst A Frič and J E Purkyně became famous zoologists The University could not escape the effects of the national revival movement, and outstanding personalities like Purkyně lectured in Czech, despite official disapproval Eventually, in 1882, the University was divided into the Czech Charles University and the German (Ferdinand) University, which retained most of the buildings and possessions

Despite difficult circumstances, the Czech professors soon began to make valuable contributions to the natural sciences The first modern chemist was Stolba, who was followed by Brauner, but only after persistent pleas was the new Chemical Institute erected in 1903, largely on the strength of Brauner's international reputation from his work on the rare earths and atomic weights A few other institutes, for example, for physics and botany, were eventually built, but the more specialized branches of science had to wait until the establishment of the republic before they had more than improvised accommodation

A number of chemists, Stěrba Bohm, Heyrovsky, Tomicek and Krepelka have followed some field of chemistry initiated by Brauner In physics F Kolacek was a pioneer in electromagnetism and the physics of the ether and V Posejpal contributed to a number of topics, including the refractivity of gases at low pressure K V Zenger was famous for his work on solar meteorology, and mineralogy (especially local) was developed by F Slavik who has frequently collaborated with British authorities In biology Purkyn had been followed by Sachs Then came F L Celakovsky, who laid the foundations of plant physiology (in which he has been ably succeeded by B Němec) and upheld the view that floral members are modified leaves In systematic botany, K Domin has continued in the tradition of foreign expeditions, notably to Australia, India and the West Indies, whilst J Velenovsky's work on fungi is a classic in that field

Many notable advances have been made by Czechs other than those associated with the Charles University The researches of Stoklasa and of Votoček and their collaborators was, for example, done at the Polytechnic, and the other universities and institutes have also contributed to scientific knowledge

The German University after the division of 1882, concentrated mainly upon the study of German literature Nevertheless work of permanent scientific value has been carried out by Rothmund in physical chemistry, E F Freundlich in astronomy, Waldschmidt Leitz in microchemistry E G Pringsheim and V Czurda in plant physiology and M Stark in mineralogy The German University served the German speaking community of Czechoslovakia and also attracted students from abroad Now that the country has lost the territory from which its students came its *raison d'être* has largely disappeared It has been reported that the German University will continue with support from Germany, but this seems doubtful, since those professors with Nazi sympathies have left The others include some who cannot be regarded as Aryans Another proposal is that the University should move to Reichenberg (Liberec) or some other town in the ceded territory but this proposal, also, has its difficulties

Their liberation in 1918 did not blind the Czechs to their obligations towards the other nationalities within their frontiers, and adequate provision was made for them in elementary, secondary, and technical schools, whilst the Germans in Czechoslovakia were the only minority to possess a university of their own. Indeed, in some ways the minority was more fortunate than the Czechs, for at the German University there was one professor for every forty students, whereas at the Czech University the ratio is one to forty-eight.

Altogether, the republic possessed some twenty-eight institutions of university rank. Advanced science teaching and original work is carried on at the universities, the polytechnics and at various special schools, such as that for mining at Pribram, the Brno veterinary college, and at forestry schools and institutes for glass technology. All have hitherto enjoyed generous support from the State. Moreover, a number of industrial undertakings have fostered specialized research work. Among these must be included the Radium Institutes of Prague and Jáchymov, the research laboratories of the Chemical Union, and those of the sugar industry, the leather trade, the forestry commission, the agricultural society and even much of the horticulture at Blatna is work of a scientific character.

As has been said before (see NATURE, Oct. 8, p. 637) various scientific and cultural institutions at Jáchymov (St. Joachimsthal), Usti (Aussig), Liberec (Reichenberg) and Opava (Troppau), to mention some of the more important ones, go with lost territory. These may still be utilized for local needs, but they are lost to Czechoslovak culture and science. More serious than this loss will be the curtailment of revenue without any compensating reduction of State liabilities, and it is obvious that the mutilated republic cannot continue to support its scientific and other educational institutions on the same scale as hitherto. A forty per cent 'cut' is to be made in the budget of the ministries, and it is to be feared that research and science will feel the full force of this necessity. The outlook for university staffs and the research workers is anything but reassuring. Amalgamations and the closing of minor institutions seem inevitable, and indeed this has already commenced.

The outlook for Czech scientific societies and publications is also serious. With diminished scope and reduced resources, many societies and their journals will find it difficult to continue unless they are able to secure assistance from abroad. Meanwhile, throughout the anxious weeks of uncertainty and national disaster, the university staffs, school teachers and public officials have shown a remarkable courage, self-denial and discipline, although for them, each and all, the future holds no security. A nation that has survived previous cultural and national disasters, coupled with persecution, will not lightly give up the struggle for a better future. First efforts must be directed towards economic survival. When this is vouchsafed it will again be possible for men of science to continue in the traditions of their distinguished predecessors.

Obituary Notices

Miss Clotilde von Wyss

By the death on November 7 of Miss Clotilde von Wyss, the world of education has lost an outstanding teacher of natural history, distinguished by her philosophical outlook and by her sympathetic attitude towards living things.

Clotilde von Wyss was born in Switzerland in 1871, and received the earlier part of her education at a school in Zurich, but from 1884 until 1891, she was a pupil at the North London Collegiate School. She was trained as a teacher at the Maria Grey College, Brondesbury, and after her course there gained distinction in the Cambridge Teachers Certificate. From 1894 until 1897, she taught at St. George's High School, Edinburgh, and during that time she was an external student at the Heriot Watt College, coming under the influence of the distinguished naturalist, J. A. Thomson, then a lecturer in the University. Miss von Wyss valued this experience extremely highly and always spoke of the late Sir Arthur Thomson with the greatest affection and esteem. From 1897 until 1900 she taught biology at the North London Collegiate School, after which she was a lecturer at the Cambridge Training College for Secondary Teachers. In 1903, she joined the staff of the London Day Training College, and here for thirty-three years she was a successful and stimulating lecturer in natural history and hygiene and a highly valued colleague.

Miss von Wyss was a brilliant and inspiring teacher. She had a wide knowledge of natural history and an infectious enthusiasm for the educational principles which she upheld. She never lost sight of the interdependence of theory and practice, and after the free and friendly discussion of school problems that prevailed in her classes, her students went out to teach with a feeling of power and confidence. She had a delightful personality, a lightness of touch and a sense of humour which helped her in surmounting difficulties and affected even the most unpromising students. Teachers of many years standing still remember her with affection and gratitude, and one of them writes, even now her advice and criticism form the sheet anchor of my everyday teaching practice Her ideals and personality have influenced many generations of students and she herself once said My family must number some thousands ' These are to be found, not only among old students of the London Day Training College, latterly the Institute of Education (University of London) but also amongst the many London teachers who attended her evening classes organized by the London County Council

Miss von Wyss was not only a successful lecturer but like all true teachers she was also continually a learner Her observations and practical knowledge of wood ants (*Formica rufa*) were used in 1936 by the Gaumont British Film Corporation in constructing a film, which not only in the spoken commentary but also in the details of the ant life shown is both artistic and educational

Convinced as she was of the value in education of the study of Nature along sound lines, Miss von Wyss helped in 1903 to found the School Nature Study Union, which stands for the sympathetic and first hand study by the child of its natural environment, particularly of plants and animals From 1906 until 1936 she was editor of the quarterly journal brought out by the Union, and the diversity and usefulness of the articles that have appeared during that time may be realized from the list of leaflets published by the Union, about seventy of which are reprints from *School Nature Study* As a colleague on the executive committee of the Union, Miss von Wyss was invariably tactful and courteous her opinions were always appreciated because they showed careful thought and sound judgment and on many occasions it was her intervention which cut the Gordian knot of a seemingly hopeless tangle

Miss von Wyss has also played an important part in the wider sphere of influence which comes under the auspices of the B B C , and her gift of the power of presenting knowledge in a simple and interesting manner has enabled her to carry her message into schools untouched in any other way She spoke and wrote with ease and clarity, and her views are to be found in many articles in educational publications and notably in her books, Living Creatures , The Teaching of Nature Study and 'The Elements of Biology"

Miss von Wyss will long be remembered as an inspiring teacher, an able and courteous colleague and a great pioneer in the school teaching of elementary biology

R F S

Prof Leonard S Dudgeon, C M G , C B E

Prof Leonard S Dudgeon who died on October 22, aged sixty two years, was educated at University College School, London, and entered St Thomas's Hospital Medical School in 1894 After qualifying, he decided to devote himself to pathology, and was appointed clinical pathologist to St Thomas's Hospital in 1903 Here he gained an extensive knowledge of morbid histology under the late S G Shattock, with whom he collaborated in several investigations, and whom he succeeded as lecturer in pathology to the Medical School

During the Great War, Dudgeon served as temporary colonel A M S in the Near East, and was consulting pathologist to the Expeditionary Force in the Balkans being mentioned three times in dispatches At the conclusion of the War he returned to St Thomas's continued his pathological work and on the retirement of Sir Cuthbert Wallace in 1928 became dean of the St Thomas's Hospital Medical School and later chairman of the Hospitals Deans Committee and a senator of the University of London

Although he contributed a number of investigations, Dudgeon was first and foremost a practising pathologist and was never so happy as when applying his pathological knowledge in the elucidation of problems of diagnosis and treatment of obscure morbid conditions One of Dudgeon's earliest investigations published in 1906 in collaboration with P W G Sargent, was on the bacteriology of aseptic wounds which showed that microbes of the *Staphylococcus* group are of frequent occurrence in wounds that heal without suppuration This subject was expanded in the Horace Dobell Lecture delivered to the Royal College of Physicians in 1908 Two or three other papers upon the staphylococci were published jointly with workers in his laboratory dealing with the classification of members of this group of microbes by means of cultural agglutination and other tests Another subject upon which he published several papers was that of *Bacillus coli* infections of the urinary tract He showed that two types of *B coli* occurred in these conditions, one hæmolytic the other not and tested the value of vaccine and other treatment upon them He was also interested in infections of the intestinal tract derived doubtless from his experience in the Balkans and he made a considerable study of the bacterial flora of the human intestine under normal and abnormal conditions

Various studies upon problems of immunity were also carried out by Dudgeon With Shattock, he investigated the phenomena of phagocytosis in human blood serum when this was mixed with horse serum, and later on phagocytosis carried out with melanin particles in which they showed that phagocytic cells vary as well as the serum Dudgeon also investigated the presence of hæm agglutinins, hæm-opsonins and hæmolysins in the blood obtained from cases of infectious and non infectious diseases in man and he brought together his studies on immunity in the Croonian Lectures delivered to the Royal College of Physicians in 1912 Blackwater fever, pathological changes in the tissues in acute diphtheritic toxæmia, the action of bile and bile salts on animal red blood corpuscles, and the reactions of the tissues and cells of the rabbit to injection of *Staphylococcus aureus*, a pathogenic agent, as compared with inert particles such as indian ink and colloidal silver, were other subjects investigated by Dudgeon, either alone or jointly with others

Cleveland Abbe (1838 1916)

On December 3 the centenary occurs of the birth of the eminent American meteorologist and astronomer Cleveland Abbe whose work at Cincinnati Observatory led to Congress passing the Act of 1870 authorizing the creation of a United States Government Weather Service and placing it under the Signal Branch of the War Department Abbe took a prominent part in the organization of the new bureau and for forty five years from 1871 until 1916 was professor of meteorology and senior scientific assistant to the Chief Signal Officer Abbe was born in New York on December 3, 1838, and graduated from the College of the City of New York in 1857 As a student he had studied Ferrel s work and this led him to a close examination of the meteorological papers then published On the outbreak of the Civil War he enlisted, but served only for a short time on account of his nearsightedness He then turned to astronomy and worked at the observatories at Cambridge Mass Pulkovo and Washington In 1868 he was appointed to the directorship of the Cincinnati Observatory in Ohio holding this position until 1873 The list of his writings on both astronomy and meteorology is a very long one and includes Studies in Storm and Weather Forecasting Mechanics of the Earth s Atmosphere and Physical Basis of Long Range Forecasting His influence on the progress of meteorology in America was outstanding and his work received recognition both at home and abroad He was made a fellow of the Royal Astronomical Society in 1876 and in 1912 the Royal Meteorological Society awarded him the Symons Medal He died at Chevy Chase Md on October 28, 1916

New International Standard for Vitamin B_1

It is announced that the first International Standard for Vitamin B_1 which consisted of an adsorbate of the antineuritic vitamin, made from rice polishings on fuller s earth, has now been replaced by a preparation of crystalline vitamin B_1 hydrochloride In recent years, progress in the study of the antineuritic vitamin has been rapid and this change in the form of the international standard has been made possible by the synthetic preparation of the vitamin in pure crystalline form Through the generosity of four manufacturers an adequate quantity of the new crystalline material was placed at the disposal of the National Institute for Medical Research Hampstead, to enable a new standard to be prepared consisting of the pure crystalline substance Extensive international investigations of the properties of this material and, in particular, the determination of its potency in terms of the original international standard by a variety of methods have now been completed, and the members of the International Conference on Vitamin Standardization have unanimously recommended that the sample be adopted as the Second International Standard for Vitamin B_1 and that the international unit be defined as the antineuritic activity of 3 micrograms of the international standard preparation This recommendation has been adopted by the Permanent Commission on Biological Standardisation of the Health Organisation of the League of Nations

As in the case of the other international vitamin standards the new standard for vitamin B_1 is held, on behalf of the Health Organisation of the League of Nations at the National Institute for Medical Research London, N W 3 and is distributed there from to national control centres established in other countries for local distribution to laboratories institutes and research workers, and to workers resident in countries in which the establishment of national control centres has not yet been completed With regard to the supply of the new standard for vitamin B_1 to those requiring it in the United Kingdom, samples have already been sent to the laboratories institutes and research workers who have hitherto received the standard adsorption product Others requiring the standard are asked to make application to the Department of Biological Standards, National Institute for Medical Research London, N W 3

National Association of Science Writers

The National Association of Science Writers of Washington, D C has been awarded the second annual Clement Cleveland Medal of the American Society for the Control of Cancer for outstanding work during the year in the campaign to control cancer" The medal was established last year by Mrs Robert G Mead in memory of her father Clement Cleveland The late Dr Cleveland was one of the pioneers in the medical profession on public education for cancer control and it was in his New York home that the American Society for the Control of Cancer was organized in 1913 The award of this medal to the National Association of Science Writers is a fitting recognition of the work of this group of American journalists in promoting accuracy as well as intelligibility in dealing with scientific topics in the Press The Association is a comparatively young body, and the fact that the award was made for work in connexion with a notoriously difficult subject, which is often the subject of exaggerated claims, enhances its value It is interesting to note that Mr J G Crowther, well known for his contributions on scientific topics to the Press in Great Britain, has been elected an associate member of the Association

Blind Landing System at Aerodromes

It is reported that 40 R A F aerodromes are now to be equipped with blind landing approach apparatus This will presumably be the Lorenz system, already in use at Croydon, Heston and Manchester civil aerodromes, and extensively on the Continent, particularly in Germany In principle it consists of a wireless beam along and down which the machine flies as it approaches the radiating station on or near to the aerodrome The waves are picked up by the aircraft s apparatus, and turned into signals arranged so that they give warning to the pilot of any deviation of his from the line of approach, both in regard to his angle to the earth and in a horizontal plane A further warning is given when it is necessary to flatten out preparatory to landing The adoption of such a system will facilitate the operation of bomber squadrons in bad weather conditions The presence of low cloud, mist or fog, is often an advantage to bombers when attacking in that it helps to screen them from fighter and ground defences It is obviously important that they should be independent of these conditions when operating from their home aerodromes The fact that these facilities may be available in emergencies for civil aircraft should encourage a more general adoption of the system in civil aviation, which will help to promote both safety and regularity in service in civil air transport

Early Races of the Far North in America

Dr Aleš Hrdlička, of the Smithsonian Institution, Washington, having completed his tenth summer season of archæological and ethnological investigation in high latitudes, has brought his exploration of the far north of the American continent to a close, and is now engaged in the examination of the skeletal remains of the Aleutian and pre Aleutian peoples, as well as of the specimens of the material culture of the latter, collected in the last three years Dr Hrdlička gave a summary of his results in his annual Smithsonian lecture, which was delivered in the auditorium of the New National Museum, Washington, on November 8 He then pointed out that when he entered upon this investigation ten years ago, it was supposed that only two peoples lived in this part of the globe, the Eskimo with the Aleut and the Indians Now six races are recognized There are two distinct types of Indians and two types of Eskimo, while it is established that the Aleut are distinct from the Eskimo The most interesting discovery made by Dr Hrdlička is, however, the sixth race, the pre Aleut people, whom he regards as close to the Shoshonean and the Californian Indian Some of them, though not all, practised mummification, and it may be that the Aleut followed them in this practice, as in a few places mummies of the two races have been found together The remains of the older people, the pre-Aleuts, show close affinities with the peoples who were discovered in the lowest levels of the old village site on Kodiak island, but whereas those peoples appear to have been exterminated in a great slaughter, the pre-Aleuts appear to have escaped this fate, although as a distinct people they have disappeared The evidence which has been gathered points to the pre Aleuts having reached these islands from Alaska, whither their ancestors had migrated at a very much earlier date from Asia Dr Hrdlička dates their coming to the Aleutians at approximately two thousand years ago

Recent Accessions to the British Museum

Among recent additions to the ethnographical collections of the British Museum (Bloomsbury) announced at the November meeting of the Trustees, were four loans by the King from the Royal collections Of these, one is a war drum carved from the trunk of a tree with human skull attached taken from the King of Ashanti at his defeat in 1826 and presented to George IV, and a Maori chief s staff of office, a combined spear and club which was presented to Queen Victoria by Maori chiefs in 1884 The National Art Collections Fund has purchased for the Museum a gold Persian wine bowl of the eleventh or twelfth century, having a Kufic inscription around the rim in praise of wine, and an ornamental design in which several realistic representations of ducks are a prominent feature Among other gifts are a collection of antiquities including small bowls dishes and scarabs of the Eighteenth Dynasty (c 1370 B C) from the excavations of the Egypt Exploration Society at Sesebi in the Sudan given by that Society, a small finely carved Egyptian lion of ivory probably dating from the First Dynasty about 3300 B C, given by Mr and Mrs Alec Rea, and a bronze head of a Pharaoh, probably Ptolemaic given by Lord Harlech, while Mr Reay Geddes has deposited on loan an Indian sculpture in stone of the eleventh or twelfth century which represents Agni the god of fire, surrounded by worshippers and goat headed attendants Mr Alvan T Marston with the consent of the Portland Cement Manufacturers Ltd has presented to the Trustees the Swanscombe skull and the bones and implements associated with it The skull and some of the implements have been allotted for exhibition at the British Museum (Natural History) while the remainder are to be exhibited in the archæological collections at Bloomsbury These implements have been pronounced to be Early Middle Acheulean, Breuil s Acheulean III

Portrayal of Weather in Art

The *Quarterly Journal of the Royal Meteorological Society* for October contains a valuable paper by Mr L C W Bonacina on "Turner's Portrayal of the Weather" Landscape features and weather are the warp and weft of scenery, and the proper understanding of Turner's work as portrayer of scenery has been greatly hindered by the fact that such artists are described as landscape painters, and further by the circumstance that the salability of their work depends largely upon giving the picture a local name Turner's pictures may be divided into two classes, those in which the *motif* is provided by the features of the landscape proper and those in which the *motif* is provided by the aspect of the weather, and the latter are probably the more important part of

Turner's contribution to nature study Mr Bonacina's detailed discussion of notable examples of Turner's pictures in the National Gallery the Tate Gallery, and the Victoria and Albert Museum deserves the careful consideration of students of both science and art The attention of these specialists and also of persons of general culture may properly be directed to the following sentence in which the outlook of the author is strikingly expressed the co ordination and unification of truth acquired on the one hand *through scientific research and on the other expressed* through artistic intuition as the intellectual needs of the age

Recent Work in Meteorology

The annual report of the Director of the Meteorological Office for the year ended March 31 1938 describes the work of a period during which attention has been focused on the ever growing needs of the rapidly expanding Royal Air Force and civil aviation Many new meteorological stations were opened during that period on service and civil aerodromes as trained staff became available The installation of direct teleprinter connexions between the meteorological stations in the country and the Air Ministry Meteorological Office headquarters was begun and arrangements for its extension to the constantly growing network of similar stations had to be considered Meteorological information for the trans Atlantic flights of July 1937 was supplied from stations set up at the Shannon Airport and at Botwood The first of these was worked on an agency basis by the Meteorological Office for the Government of Eire and the second was operated by the Canadian Meteorological Service on behalf of the Government of Newfoundland Conferences were held afterwards at Toronto and Dublin to review the meteorological organization and improve it

On the research side important work was done in collaboration with the National Physical Laboratory in developing apparatus for measuring upper air conditions by radio instruments carried on unmanned balloons, so as to obtain immediate information about wind, pressure and temperature up to greater heights than could be reached when observations were made in aeroplanes An additional advantage from the new methods is that the information can be obtained *in weather dangerous for flying* Climatic conditions in Africa during years when there were serious outbreaks of locust swarms were under investigation on behalf of the Committee on Locust Control

Electric Heating for Merchant Ships

The heating installation of a merchant ship is very different from that of a building on shore An ocean going merchant ship may sail into cold weather at any time of the year In the course of a week she may sail from tropical heat into almost arctic conditions, and in a voyage of a month's duration she may sail from winter in one hemisphere, through spring, summer and autumn, or vice versa, and come into winter conditions in the other hemisphere A paper on this subject was read to the Institution of Electrical Engineers on November 24 by H C Macewan A difficulty of arriving at a simple method of calculation like that used for computing the electric heating for a building arises from the fact that the regulations quoted in specifications are very vague Recently the British Board of Trade stated in its instructions to its surveyors in relation to masters and crew's spaces that a heating system will be considered satisfactory if it is capable of maintaining a temperature of 60° F when the temperature of the outside air is 30 F This although a useful help for making calculations is insufficient as the basis for a test to show the adequacy of the heating Mr Macewan has collected data for the calculation of quantities and gives a general review of the problem as it exists to day He points out that the capital cost of the electric heating of ships is usually less than that of other systems as it is cheaper to run electric cables than pipes In running cost also electric heating is cheap as it usually acts as a demand leveller and it is seldom necessary to run an extra generator

Broadcasting in India

In *Electrotechnics* the journal of the Electrical Engineering Society of the Indian Institute of Science Bangalore of April we learn that the Government of India is making progress with the construction of broadcasting stations In December 1937 the 5 kw medium wave transmitter at Lahore and the 10 kw short wave station at Delhi commenced operation The short wave station at Bombay—also of 10 kw started to radiate early in February and Lucknow early in April The 0 25 kw medium wave and the 10 kw short wave transmitters at Madras were put into regular service from the middle of June The Trichinopoly 5 kw medium wave station is expected to commence operation at an early date Several Provincial Governments have already distributed a small number of receivers for group listening in villages The broadcasting authorities of the Central Government have under way a programme for installing 120 receivers in as many villages in the Delhi Province At the present moment the broadcasting service touches but a fringe of the population and the programmes are of limited appeal The element of novelty and wonder is still the dominating factor in reception amongst all classes of listeners Listening for pure entertainment and enjoyment, oblivious to the mechanism, is as yet virtually non existent in India Until the present uncritical listening gives place to the habit of turning to radio for enjoyment, such questions as the acoustical requirements of studios and the special requirements demanded by Indian music and its technique can receive no adequate and satisfactory answer In this journal, Mr K Sreenivasan's thoughtful address on the design of studios for broadcasting is published

Oxford Science

The first number of a new shilling quarterly called *Oxford Science*, edited and published by the Junior Science Club, and printed at the Oxford University

Press, appeared this week. All new journals of this kind are necessarily precarious ventures but there are good hopes that this one will fulfil the need it has been produced to meet. It is taking the place of the *Transactions* of the Club which have been published now for more than fifty years. It will contain the more important lectures given from time to time to the Club, discuss problems connected with study and research in science and medicine at Oxford and review the work of the different scientific departments. The opening number contains the Robert Boyle lecture by Sir Edward Mellanby on methods of discovery in the fight against disease, an article by Prof. F. Paneth on atomic transmutation an account of recent investigations on the structure of proteins by D. Parker Riley and an article discussing and criticizing medical curricula by one of the medical tutors. Some of the articles are illustrated. There are also editorial and other notes and a few book reviews. Altogether this is a lively first number that should make a wide appeal to the student of science interested in other sciences besides his own and in the problems that their impact on the world and the university has produced.

Gardeners of Essex

THE presidential address of Dr. John Ramsbottom to the Essex Field Club provided an opportunity to present much historical gardening knowledge in a pleasant, intimate form ("Old Essex Gardeners and their Gardens", *Essex Naturalist*, **26**, 65–103, 1938). *Yucca* first flowered in England during the year 1604 in the garden of William Coy at Stubbers North Okington. This same garden also enjoys the distinction that it was the source whence the ivy-leaved toadflax, *Linaria cymbalaria*, first spread to become apparently native upon walls throughout England. It would be difficult to over-estimate the valuable work of another Essex gardener, Lord Petre, who stimulated the collection of many foreign plants which have become accepted beautifiers of British gardens. Richard Warner of Woodford introduced the genus *Gardenia* to English horticulture in 1754, and Dr. John Fothergill, 1712–80, had an influence similar to that of Lord Petre. He stimulated numerous useful projects, and himself cultivated many new and curious plants. No geographical limits were set by these Essex plant collectors, but they appear to have been especially responsible for the introduction of North American species to the gardens of Europe.

National Planning

THE Town Planning Institute has issued a report of the National Survey and National Planning Committee (price 1*s*.). The report stresses several matters of importance, and points out that in England and Wales (for Scotland is not included) about three quarters of the local authorities have applied the various Acts to about two thirds of the total land area. The process of planning, however, appears to be slow and essentially local in outlook. The Committee believes that national planning is required to supplement and reinforce local and regional planning. There is no national policy or guidance in the preservation of land for agriculture and for the reservation of national parks and other large open spaces. Further, in problems of transport, such as roadways and airports a national, rather than a regional outlook is necessary. The report contains a strong plea for a new department of Government which should take the form of a National Planning Commission. Its functions would be, first the completion of a national survey and secondly advice and guidance to other Government departments and local authorities. Thus it would be possible to formulate and execute a national policy in the utilization of land.

Earthquake in the East Indies

THE U.S. Coast and Geodetic Survey, Washington, D.C., has announced the occurrence of an earthquake on October 10d. 20h. 48m. G.C.T. with provisional epicentre lat. 1° N., long. 125 E. The epicentre was determined from instrumental data obtained at twelve United States seismological observatories. The epicentre is to the west of the Molucca Passage and the nearest town of any size is Menada in the north of Celebes. No damage has so far been reported from here. According to Dr. S. W. Visser and his colleagues of the seismological observatory at Batavia, small earthquakes are quite frequent near this spot. World-shaking earthquakes are somewhat infrequent, however, and the last ones were the swarm of *July 10–12, 1926* (epicentre lat. 1 N. long. 126° E.). It is possible that the earthquake on July 10, 1926 was multiple as the *P* residuals appear to show groupings which are confirmed by the *S* residuals.

Traffic in Women and Children

THE League of Nations Committee for the Suppression of Traffic in Women and Children recently proved by investigation that there is a connexion between licensed houses of prostitution and traffic in women. The League, therefore, sought information from many Governments and voluntary associations respecting the early lives of women who afterwards became prostitutes, and has issued an analysis of this information with comments, in a report recently issued ("Prostitutes: their Early Lives". Geneva, 1938. London: Allen and Unwin. 3*s*.). Some 60 per cent of the women were considered to be below normal in intelligence. Poverty and destitution, early seduction and the desire for an easy life seem to be the main causes responsible for women adopting this kind of life.

Monkeys as Botanical Collectors

THE *Kew Bulletin* No. 7, 1938, quotes from the annual report of the Director of Gardens, Straits Settlements, an account given by the acting director, Mr. E. J. H. Corner, of the use made of berok monkeys (*Macacus nemestrina*) to collect specimens from tall trees. Two young beroks are at present employed; they understand twelve words of Kelantanese and can thus be instructed to pick specific twigs and drop them to the ground. Mr. Corner states, "A berok upon the shoulder can be likened, in effect, to a falcon on the wrist", and its employment is recommended both to amateurs for its charm and cheapness and to keepers of Reserves where it is desirable to collect specimens repeatedly from the same trees without damage to them '

Science Masters' Association

The thirty ninth annual meeting of the Science Masters' Association will be held in the University of Cambridge on January 3 6, 1939 On January 3, Prof J Gray will deliver his presidential address on 'The Role of Science in Education" The following lectures have also been arranged Prof E V Appleton 'The Upper Atmosphere , G C L Bertram, "Animals of the Antarctic' , Prof R G W Norrish, Experiments in Photochemistry , Prof W L Bragg, X Ray Optics", Prof O T Jones, The Making of a Geological Map , Dr H B Cott, 'Visual Concealment in Nature and in War' , N E Odell, 'Everest, 1938 On January 6, a discussion will be held on 'Films in the Science Classroom' Further information can be obtained from Mr W Ashhurst, The Grammar School, Stretford, Lancs

The Night Sky in December

The night lasts for 16¼ hours in the latitude of London at the time of the winter solstice on December 22 The moon is full on December 7 and new on December 21 The moon s altitude when southing at Greenwich on December $8^d\ 0^h\ 27^m$ U T is 58½° No star brighter than mag 5½ is occulted during the month Conjunctions between the moon and planets occur as follows December $3^d\ 2^h$, Saturn $17^d\ 7^h$, Mars $18^d\ 16^h$, Venus $20^d\ 14^h$, Mercury $27^d\ 0^h$, Jupiter $30^d\ 11^h$, Saturn On December 5 there is a fairly close approach between the moon and Uranus actually resulting in an occultation of the latter as seen from parts of Asia and North America Jupiter and Saturn are both evening stars At about $18\frac{1}{4}^h$ on the following dates, the four inner satellites are grouped fairly closely to Jupiter, being easily seen in a pair of binoculars December 1^d (Satellite I occulted), 2^d, 10^d (Satellite IV occulted) ,17^d, 18^d, 19^d, 25^d to 28^d Mercury, Venus and Mars are all morning stars In mid December, Venus rises about 5^h , it is at its greatest brilliancy (mag −4 4) on December 26 The variable star, Algol, is well placed for observation during the month The approximate times of primary minima accessible to observation are on December 2^d 4 5^h, 5^d 1 3^h, 7^d 22 1^h, 10^d 19 0^h, 25^d 3 1^h, 27^d 23 9^h, 30^d 20 7^h On or about December 11 the Geminid meteors are at their maximum In the middle of the month at midnight, there is a fine array of bright stars on the southern meridian

Announcements

Prof Andrew Cowper Lawson, emeritus professor of geology and mineralogy at the University of California, has been awarded the Penrose Medal, highest honour of the Geological Society of America, "for eminent research in pure geology, and outstanding original contributions and achievements which mark a decided advance *in the science of geology*".

Prof James Kendall, professor of chemistry in the University of Edinburgh, will deliver the Christmas Lectures adapted to a juvenile auditory" at the Royal Institution on January 3, 5, 7 and 10 The subject of the lectures will be 'Young Chemists and Great Discoveries '

Mr K de B Codrington, keeper of the Indian Section of the Victoria and Albert Museum, has been appointed to give the Charles Phelps Taft Memorial Lecture at the University of Cincinnati in January Mr Codrington has been attached to University College, London for many years as honorary lecturer in Indian art and is chairman of the Indian Research Committee of the Royal Anthropological Institute He held the chair of archæology at the University of Cincinnati in 1925–26 His present invitation to the United States is an indication of the increasing interest there in India, and especially Indian art Mr Codrington intends to investigate the educational activities of various museums in the United States during his visit

The Nobel Peace Prize for 1938 has been awarded to the Nansen Office for Refugees in Geneva The Nansen Office ceases its activity at the end of this year, and its duties will be continued in London by the newly founded International Commission for Refugees The Prize will automatically be transferred to the new Commission in London, the director of which is Sir Herbert Emerson

The Geophysical Discussion at the Royal Astronomical Society on The Night Sky and Aurora , arranged for January 27, has been postponed to May 19 The discussion arranged for May 26 is cancelled On March 24, 1939, Dr L C Bullard will open a discussion on Recent Geophysical Investigations at Sea

Messrs Francis Edwards, Ltd , 33 Marylebone High Street, W 1, have issued a catalogue (No 630 1938) containing many rare examples of books relating to the sea, atlases, autograph letters, log books, etc The gems of the collection are, perhaps, a fine first edition of Sir William Alexander's "An Encouragement to Colonies ' (1624), 'Hakluytus Posthumus" of Purchas (1624–26), "The Principal Navigations" of Richard Hakluyt (1598–1600) and an atlas, the "Strassburg Ptolemy ' (1513) There is also a long series of works, with many rarities, dealing with the *Bounty* mutiny and Captain Cook s voyages Among scientific works listed we notice copies of the "Challenger Report", Sir J D. Hooker's "Botany of the Antarctic Voyage" of the ***Erebus* *and Terror***, the "Botany and Zoology of the Voyage of H M S 'Sulphur' ", Darwin's "Surveying Voyages of H M S 's 'Adventure' and 'Beagle ", and a complete set of the *Journal of the Polynesian Society*

In the short notice of J Halcro Johnson's "Reverse Notation" on p 775 of Nature of October 29, the reviewer, in quoting examples of the abundance of negative digits, inadvertently omitted the word 'minus' before log $6\ 3\bar{3}5$ According to the reverse notation, log $6\ 3\bar{3}5 = 1\ \overline{32}04$, but in converting subtraction into addition, minus log $6\ 3\bar{3}5 = \bar{1}\ 320\bar{4}$ is used

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents He cannot undertake to return, or to correspond with the writers of rejected manuscripts intended for this or any other part of NATURE *No notice is taken of anonymous communications*

NOTES ON POINTS IN SOME OF THIS WEEK S LETTERS APPEAR ON P 959

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS

Distribution of the Bridled Form of the Common Guillemot (*Uria aalge*)

THIS subject forms an excellent illustration of how character gradients in and between geographical races of animals submit to the treatment suggested by Huxley[1] In this instance, the cline— to make use of his term—is one in the proportions of polymorphs The bridled form of *Uria aalge*, a mutant, which apparently depends on a single gene difference and is distinguished by a white circle around the eye continuing backwards as a line towards the region of the nape, represents a larger percentage of the guillemot population in the north of its range than in the south It is clear that more details of this cline will reveal important facts such as the groups that are situated on it and the relationships between them During the past breeding season the British Trust for Ornithology has organized a co operative inquiry into the status of the bridled guillemot in the British Isles and, although it is hoped to continue this inquiry during the coming season to fill in the remaining gaps, enough is now known to encourage a preliminary publication

Observers were asked to visit as many breeding colonies as possible, to count at least two hundred birds from representative parts of the colony and to note the number of bridled birds in their total Fairly complete figures have been obtained except for colonies down the west coast of Scotland and Ireland, for which information is still badly needed Where two observers sent in counts for one colony, percentages were first worked out for each to find out what was the discrepancy Since this was in every such case insignificant, the counts were added together

The results for the British Isles are shown on the accompanying map, where the figures shown in circles denote the percentage of bridled birds in that particular colony

The following points illustrating the nature of the cline may be noted

(1) At all the English and Welsh colonies the percentage is very small

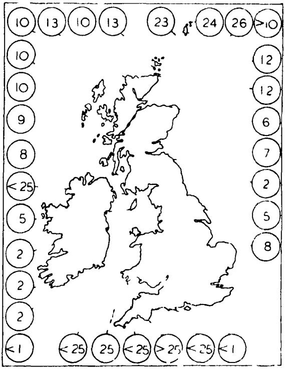
(2) At about lat 56° N the numbers commence to rise Along the east coast of Scotland there is a fairly steep and regular cline, while on the west coast there is marked discontinuity, though this may be due to incompleteness of figures

(3) Between Fair Isle and Shetland there is again marked discontinuity, the proportions rising from 10–13 per cent, which is characteristic of the whole north Scottish area, to 24 per cent

(4) In Ireland there may possibly be a gradually rising cline in a north westerly direction, but more figures are needed to confirm this

(5) In the region of rapid change off the Northumberland and Berwick coasts there is even a reversal of the cline at St Abb s Head and the Farnes showing that differences are more likely to establish themselves in such regions

As regards the rest of the guillemot s breeding range, the cline is continued northwards and southwards of the British Isles France has very occasional bridled birds Heligoland 1 per cent Gotland 1 per cent Faeroes 34 per cent Iceland more than 70 per cent, Magerö North Cape, more than 50 per cent, Bear Island more than 50 per cent and Novaya Zemlya (where only very few *Uria aalge* breed, most being *Uria lomvia*) less than 40 per cent



PERCENTAGES OF BRIDLED GUILLEMOTS AT COLONIES IN THE BRITISH ISLES

In North America, the situation in the east coast colonies has recently been studied by Johnson[2], who reports 15 7 per cent of the breeding population to be bridled Whether any similar cline from south to north is found there does not seem to be known

Another cline is also found in *Uria aalge* Birds from the southern part of the range are brownish on the back, while those from farther north show a considerably deeper colour, which is almost black. Subspecies have been named from back colour and other characters It may be significant that the change from *Uria aalge albionis* to *Uria a aalge* corresponds with the first zone of change in percentage of bridling but it does not seem safe to postulate a causal connexion between the cline in polymorph frequencies and that in melanin pigmentation on the present evidence

The genetic situation involved is of some interest From the non existence of intermediate forms it may be assumed that the control is unifactorial Whether it behaves as dominant or recessive is however, less clear, and only breeding experiments or ringing of wild populations could decide this

This method of describing sub species and forms makes a useful addition to the usual taxonomic procedure and gives important information as to the processes of species differentiation, the methods by which isolation arises in a widespread group and the speed with which genes may diffuse across such barriers

Tellurium Tetrafluoride

The formation of a white solid which accompanies the main product tellurium hexafluoride when fluorine is passed over tellurium has often been noticed but its composition has not been settled (Moissan[1], Prideaux[2]) Yost and Claussen[3] showed that the same or a similar substance is formed by heating the hexafluoride with tellurium in sealed glass tubes, but they were unable to identify the product, which they state is probably the difluoride, TeF_2

We have re investigated the reaction using sealed tubes of both glass and silica With the hexafluoride alone in the tubes, no reaction occurs and the density of the gas remains unchanged With tellurium present, a white solid is formed at a temperature of about 200° C The ratio of fluorine to tellurium in this solid is not constant but decreases with the time the tube is heated, until after heating for several days, the fluorine content becomes very small and the solid approximates in composition to TeO_2 At the same time the gas pressure in the tube rises and finally attains a value 1 5 times the initial pressure The gas, originally pure TeF_6, is converted completely into SiF_4, as shown by vapour density measurements The most probable explanation of these facts seems to be that the first product of the reaction is the formation of a new compound, tellurium tetrafluoride, which then reacts with the silica giving silicon fluoride and tellurous oxide

$$(1)\quad 2TeF_6 + Te = 3TeF_4$$

$$(2)\quad 3TeF_4 + 3SiO_2 = 3TeO_2 + 3SiF_4$$

Further investigation has confirmed the correctness of this interpretation We have found that the product of the first reaction can be isolated by using a tube composed of pure crystalline alumina This material, as supplied by the Thermal Syndicate, Ltd , is non-porous and is the only one we have found which is not attacked by this reaction

In these conditions, the tellurium hexafluoride is absorbed completely by the tellurium at about 200° C , forming a colourless solid which crystallizes in fine needles on the walls of the tube On exposure to ordinary air the solid hydrolyses very rapidly with evolution of hydrogen fluoride By dissolving this product rapidly in aqueous potash, we have been able to determine the ratio F Te in the substance Two independent experiments showed it to approximate closely to 4 1

Quite recently we have been able to prepare larger amounts of the white crystalline material free from excess of tellurium and to analyse it completely As a mean of two experiments, we find for its composition Te 62 5 per cent, F 38 7 per cent The formula TeF_4 contains Te 62 6 per cent, F 37 4 per cent The fluorine was estimated as lead chlorofluoride after precipitation of tellurium as dioxide—a method which we have found to give rather high results when used for the estimation of this element in compounds of tellurium and fluorine

The results can therefore be regarded as satisfactory, and there can be little doubt that the white solid we have obtained is a new fluoride of tellurium, TeF_4, which on account of its reactive behaviour with glass and silica and its instability in presence of traces of moisture has not been isolated previously

Further experiments on the properties and behaviour of this substance are in progress

Fate of the Sulphate Radical in the Animal Body

Phosphorus enters as phosphate in the numerous compounds in which it is to be found in the animal body , in connexion with the investigations carried out in recent years concerning the fate of ingested phosphorus atoms in the organism, it seemed to be of interest to determine whether or not, in the course of the numerous metabolic processes in which phosphorus is involved, the phosphate radical exchanges its *oxygen* content with other oxygen atoms present in the body This question could be answered by injecting into an animal sodium phosphate which contained heavy oxygen (^{18}O) as an indicator and then determining if the phosphate recovered in the urine, for example, contained more than the normal amount of ^{18}O

As, however, it was recently found[1] that 'heavy oxygen phosphate' can be obtained by dissolving sodium phosphate in 'heavy oxygen water' and vice versa, it is apparent that the oxygen atoms present in phosphate radicals exchange their places freely in water and there can be scarcely any doubt that the probability is extremely small of a phosphate radical leaving the body coupled to the same oxygen atoms with which it entered Sulphate ions, on the other hand, have been found[2] to exchange oxygen atoms either not at all or at a very slow rate with neutral water, even at 100° C , and it seemed of interest, therefore, to investigate whether sulphate ions during their circulation in the body participate in chemical reactions which loosen the oxygen bonds sufficiently to make an oxygen exchange possible

In the experiments we wish to report here, sodium sulphate containing heavy oxygen was prepared from heavy oxygen water, kindly presented to us by Prof Urey[3], having a density 740 parts in a million greater than that of normal water The reaction used for the preparation of the 'heavy sulphate was that which takes place between SO_2Cl_2 and heavy oxygen water in the presence of traces of iodine as a catalyst 1 gm of the dry material, converted into 50 c c of solution, was injected into a rabbit, we are very grateful to Miss Lindberg, of Prof Krogh s laboratory, for making the injections The urine of the rabbit was then collected for 24 hours, its sulphate content recovered as barium sulphate the oxygen content of the latter converted into water, and the density of this determined The preparation of water from the oxygen of the sulphate was carried out in the following way The barium sulphate precipitate was dried at 400° C in a stream of nitrogen and then reduced with purified carbon at 900° C, the gases evolved were mixed with a great excess of hydrogen and stored over oil in a gasometer, and, finally, the gas mixture was led over a nickel catalyst at 310° C and the water formed collected The density determination was kindly carried out by Mr O Jacobsen, using Linderstrom Lang s floating drop method

Should the sulphate oxygen during its stay in the animal, enter into exchange reactions with other oxygen atoms present in very great excess in the body, the oxygen of the heavy radicals would be replaced by normal oxygen atoms and the water prepared from the sulphate recovered from the urine would show the density of normal water If, on the other hand the sulphate ions injected retain the oxygen atoms with which they start the water prepared from the urine sulphate should show an excess density of 370 parts per million if no secretion of normal sulphate took place The water prepared from the sulphate isolated from the urine after injecting heavy oxygen sulphate has shown a very appreciable density excess—240 parts per million When comparing this value with the one calculated on the assumption that no exchange of sulphate oxygen took place, we must consider the following fact Besides the heavy oxygen sulphate– 0 84 gm of sodium sulphate being secreted in all during the day following injection—the urine contains also sulphate, even when no injection is given, the amount of which we found to correspond to 0 23 gm per day The latter is normal sulphate and its presence reduces the density excess of the water prepared from the urine sulphate

From the high density found for the water prepared from urine sulphate, one must conclude that most of the individual sulphate ions injected into the rabbit are recovered in their original form, and from this it follows that at least the greatest part of the sulphate administered leaves the body unchanged, and also that none or only a small part of the ingested ions exchange as such with other sulphate ions present beforehand in the tissues

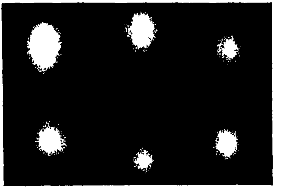
Distribution of Phosphorus in the Leg Bones of Chickens

In rickets, as is generally known, the total phosphorus content of the bones is diminished We have started now to investigate the distribution of phosphorus in the leg bones of normal and rachitic chickens with a radioactive phosphorus isotope as an indicator

The active phosphorus used was prepared by Dr F A Heyn, of the Philips Lamp Works at Eindhoven, with a Philips neutron generator[1] A fixed quantity of the active phosphorus was injected intraperitoneally as an aqueous solution of sodium phosphate of *p*H 7 2 The chickens were decapitated 22 hours after the injection and quickly sectioned The leg bones were then dissected and cleaned One of the leg bones of each bird then was divided into three parts, namely, the proximal epiphysis the distal epiphysis and the diaphysis The two epiphysial parts of the bone were then carbonized together in an oven at 200° C, the same was done with the diaphysis Preparations for the determination of the radioactivity were made in the manner described previously[2] In addition a part of the residue of carbonization was used for the estimation of the total phosphorus according to Fiske Subbarow



As was to be expected the provisional figures from eight chickens showed that the phosphorus content of the dried matter in the epiphysial part and in the diaphysial part is larger in normal than in rachitic chickens Furthermore it was observed that both in normal and in rachitic chickens the phosphorus content from the diaphysial part of the bone seems to be larger than that from the epiphysial part of the same bone

With regard to the distribution of the active phosphorus administered, it was observed that, both in the normal and in the rachitic chickens decapitated 22 hours after the injection of the labelled phosphorus, the quantity of the active phosphorus in 1 mgm of bone phosphorus was larger in the epiphysis than in the diaphysis Furthermore, it was observed that both the epiphysis and the diaphysis from the rachitic birds, decapitated 22 hours after the injection of the labelled phosphorus, contained a much larger quantity of the active phosphorus in 1 mgm bone phosphorus than the normal chickens

The second leg bone of each chicken was not carbonized, but after being cleaned was placed on a double coated X ray film It remained on this film for some days, according to the quantity of radioactive phosphorus injected The film was then developed, a clear picture of the whole bone was visible, as is shown by the accompanying photographs It is convincingly shown in these that the epiphysis contains a larger quantity of the active phosphorus than the diaphysis does Hence the results of measurements of the radioactivity of the several parts of the bone are fully in accordance with the photographs obtained

Thus it appears from the radioactivity measurements and also from the radiographs that phosphorus metabolism is more intense in the bone of the rachitic chicken than in the bone of the normal chicken and also phosphorus metabolism is more intense in the epiphysial part than in the diaphysial part of the same bone

We are now trying to investigate whether it is possible to estimate photographically the quantity of the active phosphorus present in the several parts of a bone

Finally, we wish to express our thanks to the Philips Lamp Works for furnishing the radioactive phosphorus used in these experiments, and to Mr J C de Back for his assistance in these investigations

Enzymic Deamination of Aspartic Acid

From the cell free solution of *B fluorescens liquefaciens*, which has a powerful aspartase effect[1], we have isolated aspartase by adding acetic acid up to *p*H 4 6 at 0° C The precipitate thereby formed (precipitation begins at *p*H 4 8) gives, when rapidly filtered and dissolved in *M*/15 phosphate buffer (*p*H 7), a solution which possesses considerable aspartase and also asparaginase effect This solution has no fumarase effect even in experiments of long duration

Despite the absence of fumarase, the enzyme solution obtained forms malic acid from fumaric acid in the presence of ammonia The reaction occurs also in the presence of toluene When a longer time is allowed, the reaction goes so far that only aspartic acid, malic acid and ammonia can be found in the solution, fumaric acid is not detectable If we start with *l* aspartic acid there are formed fumaric acid, malic acid and ammonia Fumaric acid is not converted into malic acid by our enzyme solution, if ammonia is absent

The results led to the conclusion that the purified fumarase free enzyme solution contains two different enzymes One (I) is the actual aspartase and catalyses the reaction

$$HO_2C\ CH_2\ CH(NH_2)\ CO_2H \rightleftharpoons HO_2C\ CH = CH\ CO_2H + NH_3,$$

the other (II) catalyses the following reaction :

$$HO_2C\ CH_2\ CH(NH_2)\ CO_2H + H_2O \rightarrow HO_2C\ CH_2\ CH(OH)\ CO_2H + NH_3$$

Thus the hydrolytic deamination of an amino acid would be established for the first time The latter reaction is not reversible The conversion of fumaric acid into malic acid in the presence of ammonia proceeds through aspartic acid Consequently, enzymes I and II are required for the reaction Enzyme II acts more slowly than Enzyme I, therefore at first chiefly fumaric acid and ammonia are formed from aspartic acid

We report the above results because Gale[2] has recently published investigations on the separation from the raw aspartase in *B coli* juice two different enzymes deaminating *l* aspartic acid One of his enzymes, however, does not act in the presence of toluene, and both of them contain fumarase, thus preventing elucidation of the mechanism

In addition, we have also noted that the aspartase effect of the enzyme solution is approximately proportional to the enzyme concentration Systematic exceptions to this rule are noted in that small quantities of enzyme act more favourably during a long reaction time than do large quantities during a short reaction time The equilibrium constant for deamination obtained with a fumarase free preparation was K_{3}, 100

With the enzyme solution or with the suspension of *B fluorescens liquefaciens* we were unable to accomplish the amino acid synthesis from oxalacetic acid and ammonia, or from succinic acid and ammonia

A detailed account of this work will be published elsewhere

Oxygen Exchange during Esterification

In a recent paper[1] on the exchange of oxygen between water and acetic acid, we pointed out that the mechanism of the exchange of the carboxyl oxygen atoms of the acid with the oxygen of the water, H–OH, was probably identical with the mechanism of esterification of an acid by an alcohol, *R*–OH, and ventured to predict that when esterification of an acid occurs in the presence of about equal quantities of alcohol and water an exchange will be observed between the oxygen of the water and that of the acid running parallel to the simultaneous rate of esterification We mentioned that we were carrying out experiments to test this view

Meanwhile, Urey and Roberts[2] have esterified benzoic acid with methanol containing excess of the heavy oxygen isotope in order to determine which linkages are broken during esterification They found it necessary to apply to their results a correction for the exchange between benzoic acid and the water formed during the esterification They therefore measured also the rate of exchange between benzoic acid and heavy oxygen water under the same conditions as those pertaining during esterification

Urey and Roberts find that 0 1505 moles of the acid were esterified, while simultaneously 0 0726 moles of the acid exchanged *both* its oxygen with those of the water Taking into account the relative concentration (or better, the activities) of the water and methanol in the reaction mixture, this result indicates that the velocity constant of the exchange reaction is about five times as great as that of the esterification This difference corresponds to a difference of only 1,000 calories in the activation energies, and we therefore consider that the above result supports our prediction

Crystal Analysis and Point Sets

IT is customary in X ray crystallography to regard a crystal as a continuous distribution of scattering matter, expressible in the form of the electron density function

$$\rho(x, y, z) = \frac{1}{v} \Sigma\Sigma\Sigma\, F(h, k, l) \exp\left[-2\pi i(hx/a + ky/b + lz/c)\right] \qquad (1)$$

$$= \frac{1}{v} \Sigma\Sigma\Sigma\, r(h, k, l) \exp\left[i\alpha(h, k, l) - 2\pi i(hx/a + ky/b + lz/c)\right]$$

Whereas X ray techniques permit the determination of the amplitudes r, they do not determine the phases α This, as is well recognized, has been the essential limitation in X ray analysis, not as a method of testing structures already proposed, but as a method of discovering the atomic structure of crystals This difficulty prompted the introduction of the derived function[1]

$$A(x, y, z) = \frac{1}{v} \int_0^a\!\!\int_0^b\!\!\int_0^c \rho(X, Y, Z)\, \rho(X + x, Y + y, Z + z)\, dxdydz$$

$$= \frac{1}{v} \Sigma\Sigma\Sigma\, R(h, k, l) \exp 2\pi i\, (hx/a + ky/b + lz/c), \qquad (2)$$

where

$$R(h, k, l) = |F(h, k, l)|^2 = (r(h, k, l))^2, \qquad (3)$$

which is thus expressible in terms of the observed amplitudes and is independent of the unobserved phases This function (representing the weighted distribution of density in the crystal about any point) can be used in conjunction with any structure already proposed, to pass it for further consideration or to reject it, according as its vector function does or does not tally with it

While in particular cases it must be agreed that passing a test of so high an order of delicacy is sufficient to establish a proposed structure to all intents and purposes the mathematical interest of the use of vector functions lies in the question as to the complete inventory of structures which satisfies a given vector map (which may be none) a question to which the method of expressing an electron density distribution in the form (1) supplies no answer For all that can be said is that all electron density functions of the form (1) share the same vector function, namely, the vector function (2), when and only when condition (3) is satisfied—and this brings us back again to the difficulty of the unobservable phases which, it would seem, the introduction of vector functions does nothing to dispel

To meet this difficulty, an alternative approach to the problem, originally introduced in a study of the structure of insulin[2] has been exhaustively developed[3] It bears to the customary approach the same relation as the quantum theory of light bears to the classical theory, picturing a crystal as a point intensity distribution in atomic space S_1, corresponding to which there is a second easily derivable point intensity distribution in vector space S_2, which may be compared with the experimentally obtained vector maps already discussed As an example of an S_2 distribution to which more than one S_1 corresponds, we may cite the periodic one dimensional arrays 3, 7, 2 5, 3, 7 2, 5 and 7, 1, 6 1, 7, 1, 6, 1, which share the same vector map It is possible systematically, in cases of gradually increasing complexity, to investigate all the S_1 distributions corresponding to a given S_2 Evidently the less symmetric the S_2 distribution, the smaller the multiplicity of its corresponding S_1 distributions This now method entirely alters the situation regarding the possibility of using vector maps to discover the atomic structure of crystals To illustrate the appropriate procedure, we discuss the projection on (0001) of the vector map of an insulin crystal[4] It is hexadic and has only four sets of marked maxima O, A, B, C shown in Fig 1, the intensities of which are in the order $O > B > A > C$ It has been found that this S_2 point distribution corresponds to two and only two S_1 point distributions shown in Figs 1 a and 1 b But the fact that the intensities of the S_2 points are in the order $B > A > C$ excludes the second of the two S_1 point distributions

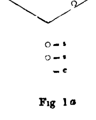

Fig 1a

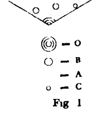

Fig 1

Fig 1b

Hence we deduce that, whatever the degree of approximation to which the point distribution in Fig 1 represents the vector diagram of insulin to that same degree of approximation the corresponding atomic distribution in crystalline insulin is represented by Fig 1 *a* (broken circle *c* appears at the centre and at each corner of the hexagon)

This procedure is further explained and developed in general in more detailed studies in course of publication It is also being used to derive from the vector diagrams of insulin further and more detailed information regarding the atomic structure of crystalline insulin in investigations which may be regarded as supplementary to those already published[3] [4], which have shown the delicate concordance between these diagrams and the vector map of the cage structure predicted for insulin[6] as a deduction from the cyclol hypothesis[7]

Ionization of Air in an Air conditioned Building

According to modern medicine, the electric condition of atmosphere is an important sanitary factor In closed localities ventilated normally, man lives in a medium which has not the electric field of open air but the average ionization of its air is, as a rule the same as in the open air There is normally also a slight excess of positive ions over negative ions as out of doors Cellars where the air stagnates and where there is accumulation of radon (radium emanation) released from the walls are an exception

It was therefore interesting to ascertain the order of ionization of air inside buildings provided with Carrier air conditioning equipment

This equipment consists, in principle, of filters (viscous layers, glass or steel wool, etc) or electric precipitators and air washers freeing the air from dust, and adjusting its humidity and temperature It might be expected that the air is simultaneously freed also from its ions, which may be regenerated in the cleaned air only by the influence of radio active radiation of the walls and other articles placed in the building, or by cosmic rays

We had the opportunity of measuring ionization of air in the central office building of the municipal electricity works of the city of Prague The central air conditioning equipment, described by one of us[1], consists of the main filters having a total surface of 48 sq metres, after which the air passes through a chamber where it is washed with water After being heated suitably, to adjust the humidity and temperature, the conditioned air is led through the main duct to the individual stories It passes there through the local machines, where it is mixed with the return air cleaned by local filters From the machine rooms, the air is guided in metal air ducts and inlets with grids, into the working rooms The ducts are provided with silencers made of 'Celotex and Fritex to reduce sound The amount of air drawn in per hour from the open atmosphere is 60,000 cub metres minimum, 200,000 cub metres maximum

The content of small ions was measured by a compensating ion counter of special design[2] giving directly the number of small ions in 1 c c

The results are given in the accompanying table, where n^+ and n^- are the number of small ions in 1 c c of air q is polarity of spatial charge The average temperature of the conditioned air was 19° C, relative humidity 62 per cent except measurement No 2 when the temperature of air was 12 3° C and relative humidity 89 per cent

	Place	n^+	n^-	$q = \frac{n^+}{n^-}$
1	Outside air (open atmosphere)	300	260	1 15
2	Pit immediately behind the air washer	530	10 600	0 05
3	In the main duct for conditioned air 1st floor	640	5 300	0 121
4	Ditto 4th floor	550	4 650	0 118
5	Air inlet into the working room	200	1 900	0 105
6	Close to the wall of the working room 70 cm above the floor	60	330	2 30
7	In the middle of the working room	7	895	0 866

Measurement No 2 shows that the air is not freed from ions even after it passes through filters and is washed with water There is an enormous excess of negative ions forty times more than in the open air which is evidently the Lenard effect that is separation of negative charges on breaking up water drops A considerable excess of negative ions over the positive ones is maintained in the main duct for conditioned air up to the 4th floor at an average speed of air of 195 metres per minute The radio active radiation of material of the walls and articles renews quickly (in about 10–15 minutes) the balance between the positive and negative ions The walls tend to eliminate the negative ions the mobility of which is greater than that of the positive ions so that they are more absorbed on objects (see measurement No 6) The average ionization ascertained in the working rooms, in the corridors and in the hall was twice as high as in the open air, the air showing as a rule a slight excess of negative ions over positive ions that is, inverted polarity as against the normal polarity of open air Permanently increased ionization of air in an air conditioned building may have a certain physiological influence It resembles a mountain climate, which is characterized always by a greater ionization than that of the lowlands

Velocity of Sound in Liquid Helium

Burton and others[1] have measured the velocity of ultra sonic waves in liquid helium under its own vapour pressure, and compared the results with the thermodynamic properties of the substance In the helium I range they derive an adiabatic compressibility, which shows a minimum at 2 5° K In order to find the isothermal values, we have to multiply by $\gamma = c_p/c_v$. γ can be calculated from the specific heat[2] at vapour pressure c_s with the help of the thermodynamic

T °K	
	1 [illegible]
[illegible] 0	1 [illegible]
3 0[illegible]	1 3
3	1

diagrams[3]. It is interesting that in the isothermal curve the minimum has disappeared. The minimum in the adiabatic compressibility is connected with the rapid rise of c_p/c_v above the λ point.

Vowel Vibrations and Vowel Production

PROF. E. W. SCRIPTURE, in a letter published in NATURE of October 1, suggests that the profiles of the various vowel sounds of which he gives examples—indicate that these sounds cannot have been produced by resonance.

I showed, in 1923 and 1924[1], that all the English vowels and consonants could be recognizably produced by the use of coupled resonators (of the Helmholtz type) suitably tuned to produce the principal resonant components that had been recognized by ear when listening to the speech sounds themselves—when those sounds were breathed or whispered. If the resonators were energized, by blowing (turbulent) air through or into them, they reproduced 'unvoiced' speech sounds. If they were energized by pulsating air—produced by first passing the energizing air current through a vibrating reed (equivalent to the vibrating action of the vocal cords)—the resonators reproduced voiced speech sounds. Incidentally, it was shown that vowel sounds could also be produced by coupling the resonators in parallel instead of in series.

That the resonant components were not imaginary was afterwards shown by I. B. Crandall and C. F. Sacia, of the Bell Telephone Laboratories[2], who proved their existence (together with other subsidiary resonances, not detected by ear) by purely instrumental means. Later, John Q. Stewart[3], in the Research Laboratory of the Western Electric Company of New York, and Dr. W. H. Eccles[4] showed that similar, recognizable, voiced vowel sounds could be produced by substituting electrical tuned circuits for Helmholtz resonators, and intermittent electrical impulses, in the place of intermittent air pulses for energizing the resonators. The resulting complex current, amplified and passed into a loud speaker, produced the voiced vowel sounds. In all these experiments, vowel (or in some cases also consonant) sounds were produced by the action of resonators.

It must be admitted that, in the case of human speech, the resonant conditions are more complex than in the experiment cited. The human pharynx, in particular, constantly varies in form during speech; the vocal cords also—as Prof. G. Oscar Russell has shown at Ohio University[4]—appear to modify their attitude, so as to assist the resonant effects. They probably supply a reed note which is rich in resonant components of about the right frequency to energize the principal oral resonance of each vowel sound.

There is the further difference that whereas the impulses produced experimentally by the artificial reeds (or equivalent) were relatively constant in frequency, those produced by the vocal cords are highly variable. But the evidence of the models appears to be conclusive that the human vowel sound is essentially an effect of resonance.

My own time is now fully occupied with the investigation of other aspects of human speech; but if any physicist (preferably in London) would care to make profiles of the artificial vowel sounds produced by some of my resonators, to compare with those of human speech—I would gladly lend them for the purpose of the experiment.

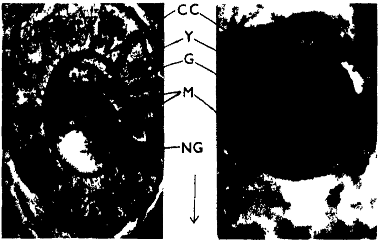
Effect of Ultra-centrifuging the Oocytes of the Mouse

OVARIES of the mouse were centrifuged in the Beams ultra-centrifuge. In the young oocytes the cytoplasmic inclusions and components are stratified into three layers. The mitochondria occupy the centrifugal end of the cell. The Golgi material and the nucleus, together with a few small granular mitochondria, are situated in the middle region of the cell, while the centripetal end is filled with clear cytoplasm which may contain a few small Golgi elements.

The accompanying illustrations are photomicrographs of two older oocytes. With the growth of the oocyte a layer of non-granular cytoplasm makes its appearance at the centrifugal pole ((a), N.G). At a later stage a layer of deeply stained material is present centripetal to the Golgi layer (G); this is identified as yolk (Y). In the mature oocyte the mitochondria (M) occupy the centrifugal half of the cell, while the Golgi material forms a thin layer centrifugal to the clear cytoplasm in the centripetal end of the cell (C.C). As in the earlier stages, a few small Golgi elements may lie in the cytoplasm towards the centripetal pole. The yolk lies between the Golgi layer and the centripetal pole. At this stage the nucleus (not shown in the photomicrograph) is displaced towards the centrifugal end.

The presence of a non-granular layer at the centrifugal pole of oocytes of a certain age, and its absence from the young and from the mature oocytes, must be due to changes in viscosity correlated with the growth of the egg. It is also of interest that the position of the nucleus varies in eggs of different ages.

So far as I am aware, the only published work on the centrifuged mammalian egg is that of Beams and King[1], for the guinea pig egg. Beams and King do not mention a layer of non-granular cytoplasm at the centrifugal pole at any stage in the development of the egg of the guinea pig, nor do they record a marked change in viscosity correlated with the growth of the oocyte



(a) (b)

An examination of centrifuged oocytes of the mouse, fixed in formol and stained with Sudan IV, failed to reveal the presence of fat The absence of fat from the mouse egg agrees with previous findings for the uncentrifuged oocyte[2]

This work was carried out at the University Zoological Department, Trinity College, Dublin

A Modified Phase Rule Equation

The interesting and useful modified phase rule equation recently proposed by Dr. S T Bowden[1] contains what he calls a restriction term, *r*, which "is equal to the number of pairs of phases having the same concentration or composition".

In applying the modified phase rule equation to one-component systems, however, it appears that *r* must be equal to the number of pairs of phases which are *identical* Sublimation, fusion, evaporation and the triple point in one-component systems all involve pairs of phases which have the same concentration or composition Now at the triple point, for example, Dr. Bowden's equation reads

$$3 + 0 + 0 = 1 + 2 - 3,$$

which is not correct At the critical point of a pure substance, however, where the liquid and vapour phases are usually supposed to become identical[2], Dr Bowden's equation reads correctly

$$2 + 0 + 0 = 1 + 2 - 1.$$

George Novello Copley.

---

[1] Nature, **141**, 331 (Feb 19, 1938)

[2] See "Symposium on the Critical State, etc", *Chemical Reviews*, **23**, 1 (1938); Traube, I, *Trans Faraday Soc* **34**, 1234 (1938)

I am obliged to Mr. Copley for pointing out what appears to be an ambiguity in the use of the expression 'concentration' in the definition of the restriction term of the modified phase rule. Naturally, in the case of unary systems, the restriction term refers to identity of the phases and for a system at the triple point, $r = 0$, since the phases are not identical Accordingly, we have

$$P + F + R = C + 2 - r$$
$$3 + F + 0 = 1 + 2 - 0,$$

which is correct I made no reference to this simple example in my first communication because it is easily solved by means of the ordinary Gibbs equation

Actually, the restriction term was defined to cover the more complicated cases, and it was taken for granted that the restriction referred to phase identity in all simple unary systems At the time of writing, I was unaware that T W. Richards[1] had also pointed out that much of the subtlety of the phase rule lies in the restrictions imposed on the system "when one individual is kept in a definite weight ratio or at a definite concentration in a variable phase". The matter is explained in more detail in my book on the phase rule[2], where for simplicity the expression 'identity restriction' is employed throughout.

Apart from the fact that the equation gives a correct interpretation of all the cases cited by Mr. Copley, I may add that its primary aim was to supply a more informative rule, capable of distinguishing between physical and chemical change

[2] "The Phase Rule and Phase Reactions" (Macmillan and Co, Ltd, 1938)

A New Decalcification Fluid

Decalcification of tissues by means of the usual acid reagents is rarely satisfactory, and unless carried out carefully and slowly the evolution of carbon dioxide leads to the production of artefacts This disadvantage is particularly felt in dealing with the highly calcified integuments of some Crustacea

To overcome the difficulty, tissues, after fixation, have been treated with aqueous solutions, in strengths up to 30 per cent of a neutral salt, of sodium hexametaphosphate. Complete decalcification of such a decapod as *Porcellana* (which would take at least a week in acid) was effected in a day and, since the reaction involved is a simple replacement of calcium by sodium, no distortion occurred. All the products of the reaction are water-soluble and are removed by washing in water:

$$2CaCO_3 + \underbrace{Na_2\{Na_4(PO_3)_6\}}_{\text{Sodium hexa metaphosphate}} = 2Na_2CO_3 + Na_2\{Ca_2(PO_3)_6\}.$$

The method was also used on echinoderm and mollusc material and, although the process was slightly slower, the results were equally successful.

Mammalian bone was also softened, but the penetration was much slower Despite the fact that the reagent is only water soluble, it is sufficiently rapid in action not to cause maceration or damage to the tissues, and in all the material tested the histology was particularly excellent

It should be emphasized that, as the salt is insoluble in alcohol, it must be well washed out, and the fixative employed before decalcification must be one which admits of this treatment

Binocular Illusion

IN the correspondence on this subject, there does not appear to be mention of the faculty for viewing stereoscopic photographs possessed by those who can comply with Mr J D Morton's manner of viewing a lattice[1]

In this case, as distinct from the binocular sequence described by Sir Richard Paget[2] and others, the eye axes are turned more nearly parallel than normally, while keeping the focus adjusted to the lattice distance The suspended image is then apparently behind the pattern

Now this optical condition is that necessary for viewing a pair of stereoscopic photographs, without mechanical aid My own eyes tend to move their axes apart more readily than to converge from the normal angle for focused vision at medium distances They will even diverge about 1° out of parallel - shown by the fact that I can see a single binocular image formed by two similar objects 1 ft apart, at a distance of about 50 ft A pair of stereoscopic photographs are easily seen in correct perspective' —more easily than with a lens viewer' in fact

The late Mr R C Clinker, chief of the B T H Research Laboratory, was also endowed with this faculty, I believe but I have not met many other persons who were

Points from Foregoing Letters

A MAP showing the percentage distribution of the common guillemot, *Uria aalge*, having a white circle around the eye (bridled form), at various points around the coast of the British Isles, is submitted by H N Southern The bridled form apparently depends on a single gene difference and the survey of its cline gives important information as to the process of species differentiation

The preparation of tellurium tetrafluoride, which on account of its reactive behaviour with glass and silica and its instability in the presence of traces of moisture had not been isolated previously, is described by G A R Hartley, T H Henry and Prof R Whytlaw Gray

From the finding that the greater part of the sulphate (containing heavy oxygen for identification purposes) which had been injected into a rabbit was afterwards recovered unchanged in the rabbit's urine, A H W Aten, jun and Prof G Hevesy conclude that only a small part of the ingested sulphate ions exchange with the sulphate ions already present in the tissues

The distribution of phosphorus in the leg bones of normal and rachitic chickens has been investigated by Dr M J L Dols and Prof B C P Jansen in collaboration with Prof G J Sizoo and G J van der Maas A radioactive isotope of phosphorus was used as an indicator The phosphorus metabolism seems to be greater in the rachitic birds than in the normal chickens, and it is greater in the epiphysis than in the diaphysis of the same bone These results were confirmed by radiographs.

From the cell free solution of *B fluorescens liquefaciens*, Prof A I Virtanen and J Erkama have obtained a mixture which seems to contain two new enzymes one of these catalyses reversibly the reaction aspartic acid ⇌ fumaric acid + ammonia and the other leads, through hydrolysis, to the irreversible deamination of aspartic to malic acid

Dr Dorothy Wrinch describes a new procedure for deriving the crystal structure from the intensity maxima in X ray diagrams and shows how this can be applied in the case of insulin to derive from the vector diagrams the cage structure based on the cyclol hypothesis

A table showing the concentration of positive and negative ions in the air, as affected by air conditioning in closed buildings, is given by Dr F Běhounek and J Kletschka There is a large temporary increase in the number of negative ions due to the break up of water droplets, but this is soon reduced by the action of the walls and other objects in the room

H J Groenewold finds that the maximum in the velocity of sound in helium I is connected with the rise of c_p/c_v above the λ point

Commenting on Prof Scripture's statement that vowel sounds cannot have been produced by resonance, Sir Richard Paget recalls some of the evidence in favour of the resonance hypothesis and offers the loan of some of his resonators to make profiles of the artificial vowel sounds for comparison with those of human speech

Dr R A R Gresson has centrifuged the ovaries of the mouse in the Beams ultra centrifuge The cytoplasmic inclusions and components of the oocytes are stratified according to their specific gravity An examination of oocytes of different ages indicates that there are changes in viscosity correlated with the growth of the egg Treatment with Sudan IV failed to reveal the presence of fat in the centrifuged egg of the mouse

Mr R A C Wilks recommends sodium hexametaphosphate in aqueous solution as a decalcifying fluid It acts rapidly and has the advantage over other fluids of replacing insoluble calcium by soluble sodium compounds without the evolution of gases, thus enabling delicate histological structures to be preserved without distortion

Research Items

American Indian Place Names

Dr John P Harrington has been engaged in an investigation of the origin and meaning of some well known American place names of Indian derivation A preliminary report issued by the Smithsonian Institution, Washington deals with certain of his results Utah, it has been assumed generally was taken directly from the tribal name the Utes of the people who lived in this territory originally This, however, was not their own name for themselves, but one bestowed upon them by the Navajos and Apaches In Navajo linguistics, it would appear the term is derived from the word for upper and the name means the upper people, hill dwellers or highlanders Cheyenne is a direct derivation from the Sioux word meaning barbarian', or one who does not speak our language It may have conveyed dislike or contempt as the Sioux regarded the Arapahos, Crows and others in the Cheyenne River valley as intruders into territory which did not belong to them Tacoma is a mispronunciation of Puget Sound Indian for snowy mountain, Ta ko bed, a name applied to Mt Ranier, Mt Baker Mt Hood and Mt McLaughlin, which early settlers mistook to be a specific name for Mt Ranier Seattle at present is unexplained It derives directly from Seh Ahl', the name of an influential Indian at Lake Union, but names of individuals usually had some definite meaning In this instance, it defies analysis Manitoba is relatively easy It means land of the spirit, and comes from the Algonquin word Manitoowa', meaning spirit It was a generic term, identical with the term manitu in eastern dialects

Swineherds Disease

E Fried (*These de Paris* No 139 1938) who records three illustrative cases in men aged 27, 28 and 29 years, states that this new infectious disease which is also called swineherds benign meningitis, swineherds meningo typhoid and fruiterers disease, has hitherto only been found in certain parts of France (Upper Savoy) Switzerland and Italy, where it has been described by Bouchet (1935), Muller (1932) and Penso (1934) respectively It is an occupational disease which affects both sexes equally The pig is the probable source of infection either directly by its dejecta or indirectly by an intermediate host such as the louse The disease has been reproduced experimentally in man and in certain animals besides the pig, such as the rat, cat, ferret, monkey and mouse The pathogenic agent is a filterable virus which is found in the blood between the second and sixth days of disease, and is eliminated in the urine and fæces The cerebrospinal fluid is much less virulent than the blood The virulence of the brain, spleen and liver has not yet been determined The disease runs its course in three successive stages The first is characterized by moderate fever, vomiting, diarrhœa and a polymorphous eruption Then follows a period of remission in which the fever and other symptoms subside In the third stage the temperature rises higher than before and a meningeal syndrome develops Spontaneous recovery takes place, and no sequels ensue

Nature of Lachrymatory Substance in Onions

According to Science Service, E F Kohman has suggested at a meeting of the American Chemical Society at Milwaukee, September 1938, that the lachrymatory substance in onions is aldehydic Mr Kohman suggests that these aldehydes may account for the putative value of the vegetable in cases of colds, as a palliative for rheumatism and arthritis etc Pre treatment of the seeds with formaldehyde controls smut disease in onions, after planting Kohman suggests that these aldehydes are developed the onion itself thus maintaining its resistance

Rodents from Galapagos Islands

The native species of Galapagos rodents belong to two closely related genera *Oryzomys* and *Nesoryzomys* of which all the endemic species known to occur in the island were represented in the California Academy of Sciences Expedition of 1905 6 with the one exception of *O galapagoensis*, which has not been taken since Darwin's visit in 1835 Re examination of the Expedition s collection by Robert T Orr has brought several new facts to light (*Proc California Acad Sci*, Ser 4, 23 303, Sept 1938) Two examples of *N darwini* from Indefatigable Island bring the known examples of that species in collections up to six From James Island from which no mammals had previously been recorded four specimens of *Nesoryzomys* were obtained, and these present characters sufficiently distinct to warrant the creation of a new species, *N swarthi* which the author describes The type specimens were collected in July 1906, and since more recent expeditions have failed to collect this species, the possibility exists that it may now be extinct as the result of competition with introduced Old World rats Examples of *Rattus rattus alexandrinus* were obtained on James Island during the visit which produced the native species

Internal Fluid of Ascidian and Sea Water

The resemblance in composition between internal fluids and sea water is further illustrated by an analysis of the Pacific Ocean ascidian, *Chelyosoma siboja*, by Satarô Kobayashi (*Sci Rep Tôhoku Imp Univ*, Ser 4, 13, 25, 1938) In this case the inorganic composition of the perivisceral fluid which surrounds the heart almost exactly corresponded with that of sea water at the Biological Station of Asamushi although there were slight discrepancies as regards potassium and magnesium The freezing point depression, 1 95, was also almost identical with that of sea water On the other hand, the composition of the perivisceral fluid differed remarkably from that of the blood fluid (body fluid), especially of the corpuscle fluid as formerly described by the same author The body fluid in the test arises from the blood vessels distributed in the test and in the soft body, and the blood sinus on the ventral side of the ascidian body is the connecting link between the two groups of vessels. Although in the cartilaginous test no trace of acid was detected, both test fluid and blood fluid gave an acid reaction, and the source of this acid appeared to be in the cell sap of the relatively large vacuolated vesicular cells in these fluids

Cave Fauna of Yucatan

An interesting quarto memoir on this subject has recently appeared as Carnegie Institution of Washington Publication, No 491 (June 1938) With an introduction by Mr A S Pearse, of Duke University, there follow some twenty three articles by a panel of specialists on the various animals collected in these caves, together with a short account of the fungal flora The Yucatan caves, it may be added, were visited by Mr Pearse in 1936 Altogether twenty seven were examined, and most of them are of the so called two cycle solution type and occur below ground water level, being formed by the passage of water which contains carbon dioxide, through limestone Their form is irregular with high vaulted chambers and without evidence of streams or large pools Some other of the Yucatan caves are evidently produced by faults while the limestone sheet which forms this peninsula was being elevated More than three hundred species of animals were collected in these caves by Mr Pearse and of these 78 are described as new in papers in this memoir, as well as 19 new genera About one tenth of the fauna encountered were troglobites or exclusively cave types One fifth of the animals were troglophiles, or those which live in caves and may breed there but live outside also The others were trogloscenes, or animals which occur in caves as accidental guests but may live indefinitely outside these number about seven tenths of the fauna Among the important troglobites of Yucatan are arthropods and vertebrates —shrimps, isopods, millipedes, chelonethids, spiders, collembolans, crickets, ants, together with a brotulid fish and a symbranchid eel

Evolution of Annelida, Onychophora and Arthropoda

In an informative and stimulating publication R E Snodgrass (*Smithsonian Misc Coll*, Aug 1938) has set forth in considerable detail his views on the evolution of the Annelida, Onychophora and Arthropoda To do this he has considered in sufficient detail to support his thesis and to allow of a discussion of metamerism, the development of non specialized members of the three groups Further the structure of the adult is considered, system by system, fully enough to permit discussion of the homologies of various organs in the different groups and also those organs which, while superficially resembling one another, cannot be regarded as homologues Certain lines of divergence from the generalized examples are also indicated All this is done in a critical manner and illustrated by 54 figures, a number of which include as many as six or seven drawings, some original but most taken from other authorities To document the statements, a reference list of 173 works is provided, this includes the most recent and the most important papers The last part consists of what the author terms phylogenetic conclusions, and this occupies 16 pages and is divided into 25 paragraphs Here are set out clearly and succinctly the deductions drawn from the data furnished in the preceding pages and a suggested phylogeny of the groups The author postulates as an ancestral form a planula like organism with a posterior blastopore This by adopting a creeping habit is presumed to have become elongated, and as a result of creeping on the blastopore surface this aperture became correspondingly elongated The mid region of the slit then closed up, leaving an opening at each end, a subterminal mouth anteriorly and a terminal anus posteriorly, and *connecting the two an alimentary canal* Henceforward the transformations into the three groups are followed by more close reference to actual developmental or adult conditions

Soil Organisms and Seed borne Pathogens

A brief but interesting note by A W Henry and J A Campbell (*Canadian J Res* 16, No 9, Sept 1938) directs attention to an aspect of the natural fauna and flora of the soil which is certainly not usually held in mind Two diseases of flax, the browning caused by *Polyspora lini* and the anthracnose disease, *Colletotrichum lini*, are both frequently carried by infected seed The authors supply very definite evidence that the infection of the crop from this source is much heavier when it is sown in sterilized soil than in untreated soil The reduction in infection thus brought about by the natural action of other soil organisms is indeed more effective than pre treatment of the seed with various sterilizing agencies, unless this treatment is so drastic as itself to reduce very considerably the germination of the seed On the other hand, preliminary experiments with certain smut fungi, causing bunt of wheat, suggest that in this case the natural soil does not inactivate the seed borne pathogens, so that the disease may be as prevalent upon plants grown in natural as in sterilized soil

Zygnemales from Northern India

The slowly flowing streams of the plains of the Fyzabad District are rich in species of this group, and Randhawa has made a thorough survey over a period of two years (*Proc Indian Acad Sci* 8, Sect B, 1938) In streams which dry up during the hot weather it is interesting to find that many species do not germinate until some months after the refilling of the water channels The streams contain water from July onwards a few species germinate at the end of August and are prolific by the end of September but the majority of the species do not germinate until December On this basis, the species fall into three groups a small group of late autumn and early winter annuals, a large group of late winter and spring annuals, and a small group of ephemerals This is summarized in a chart which also shows the period of conjugation An interesting species is *Zygnemopsis minutum* The plant is filamentous, but the cells are loosely connected and fall apart prior to conjugation The free floating cells meet and fuse in any direction, giving rise to zygospores of very varied forms This species bridges the gap between Saccoderm desmids and filamentous Zygnemales A useful survey of characteristics used for generic and specific identification precedes the description of the species

New Records of the Larger Fungi

Mr A A Pearson has cleared up several taxonomic puzzles of the larger Basidiomycetes, in a recent communication (*Trans Brit Mycol Soc*, 2, Pts 1 and 2 27–46, Aug 1938) Two new species are described, namely, *Tricholoma inocybeoides* and *Mycena uracea*, and both are illustrated in colour Of most general mycological interest of Mr Pearson's paper, however, will probably be his descriptions of various species of the genus *Russula* in relation to three chemical tests Sulphovanillin, phenol and ferrous sulphate give distinctive colour reactions with many species, and these are included in the descriptions of twelve uncommon kinds Two species of *Inocybe* have been transferred to the genus *Astrosporina* by virtue of their spore characters They are now *A decipientoides* and *A napipes*

Insect Transmission of Maize Streak Virus

Some interesting results of experiments on insect transmission of maize streak virus have recently been published by H H Storey (*Proc Roy Soc*, B, 125 455–477, Aug 1938) Special attention has been given to the part played by puncture of the plant s tissues by the insect *Cicadulina mbila*, in transmission It seems necessary, in this particular host virus combination for the insect s proboscis to reach the phloem tissue in the host, and infections fail if this degree of penetration is prevented artificially Punctures maintained for less than 5 min fail to infect, and it is concluded that the insect inoculates virus in distinct doses Each dose appears to be independent in its effect of any other doses inoculated by the same or another insect The vector can take up virus from the mesophyll in a chlorotic area of a diseased leaf but cannot take it up from either the mesophyll or phloem of a green area Probability of infection, moreover is not diminished by the removal of inoculated leaf tissue shortly after the inoculation so the virus must spread with considerable initial rapidity

Boundary Waves at a Surface of Discontinuity

Prof K Sezawa and K Kanai, in a very valuable paper (*Bull Earthquake Res Inst*, *Tokyo Imp Univ*, 16 Pt 3, Sept 1938), have recently followed up the work of Stoneley on Love and Rayleigh waves (*Proc Roy Soc*, A, 106) by discussing the formation of such boundary waves In this, they have used a method of calculation similar to that employed by A Sommerfeld (*Ann Phys*, 4, 28, 1909) and make the problem two dimensional They obtain equations for dilatational waves, distortional waves in a horizontal plane and distortional waves in a vertical plane paying particular attention to the amplitudes of such waves at both large and small epicentral distances One outcome is that larger amplitudes are to be expected in the horizontal distortional waves than in the other two at all epicentral distances A second is that in the case of dilatational primary waves and distortional primary waves with amplitudes orientated in a vertical plane, the energy of the body waves is converted usually into boundary waves in passing through or in being reflected from a surface of discontinuity In the case of distortional waves with amplitudes orientated horizontally, no boundary wave is formed A third is that the large amplitudes of S_cS which sometimes exist may be explained on the above theory Sezawa and Kanai modestly say that their present work is really only qualitative and that they are investigating the three dimensional problem more rigorously

Corresponding States

In a discussion of an equation of practical interest for gases removed from the ideal state, F G Keyes (*J Amer Chem Soc*, 60, 1761, 1938) has examined the equation $B_0 p_c/T_c = -R\theta f(\theta)$, where p_c, T_c are the critical pressure and temperature, $\theta = T/T_c$ is the reduced temperature, and $B_\theta = \beta - A/RT - (\alpha^2)A^2/(RT)^2\beta^2$, where A, β are constants, α^2 is a quantity which may vary from substance to substance It is suggested that

$$B_{\theta 0} = \beta_\theta - A_\theta/\theta - C_\theta/\theta^3$$

where β_θ, A_θ and C_θ are expected to be the same regardless of substance This has been shown to be the case for a number of different substances, but the value of C_θ is different for non polar and polar substances It is noteworthy that the constants are derived from values of the van der Waals constants, and hence the van der Waals type of molecular field is assumed to be valid It is shown that the reduced equation is useful in making approximate physico chemical calculations involving gases under pressure

Specific Heat—Temperature Relationship of Certain Steels

At the adjourned autumn meeting of the Iron and Steel Institute a paper of very considerable importance was presented by Dr C Sykes and Mr H Evans For many years past, there has been evidence that in commercial iron and steel certain abnormalities occur at temperatures below the carbon change point Dearden and Naesar have found such abnormalities in the specific heat relationship at 120° C Using a very delicate method Sykes and Evans have failed to find this point and it must be accepted that, at any rate in the materials with which they have dealt, no such abnormality occurs in the specific heat With the exception of a slight deviation at the temperature at which the iron carbide becomes non magnetic, all their curves, both for iron and for carbon steels are smooth By introducing into their test pieces small amounts of low melting point metals of known latent heat, they have proved that changes of the order of those previously observed could not have been missed with the experimental technique which they have employed It is pointed out, however, that these results are not necessarily incompatible with abnormal changes in the mechanical properties of the materials

New Diffraction Gratings

Prof R W Ditchburn, of the University of Dublin has recently discussed the problem of diffraction by gratings with irregular spacings and finds that they may be designed so as to give with fewer elements the same resolving power as gratings with equal spacings (*Proc Roy Irish Acad*, 44, A 1938) For echelon gratings with an even number of plates, each plate of thickness a small multiple of a fundamental thickness, and the plates equidistant from the middle plane of the grating of the same thickness, he shows that the diffraction pattern produced may be predicted without much difficulty Thus for an echelon which would normally have 56 plates if each 13th plate from the centre plane be of the normal width but of 7 times the normal thickness so that it replaces plates 7 to 13, the 20th plate and the 27th plate of three times normal, and the inner part of each widened step be covered by an opaque screen which reduces the transmission width of the step to the normal width, the resolving power of the 36 plate echelon produced is equal to that of a 65 plate echelon of the usual type A similar improvement of the plane ruled grating is produced by ruling groups of about 50 lines with the centres of the groups at certain irregular specified distances apart, which leave unruled spaces between groups, and the unruled spaces are covered by screens, 60 per cent of the ruling is saved and the resolving power of the grating is increased 10 per cent

The Present Position of Sociology*

IN considering the achievement of sociology, the principal problems can be set out under four heads

Social Morphology, including (1) the quantity and quality of the population in so far as this affects social relations and the character of social groups, and (2) social structure, that is, the classification and analysis of the principal types of social groups and social institutions

On the qualitative side, early studies were dominated by the hypothesis of racial differences in mental character without realization of its difficulties Their successors are represented by the eugenists and the numerous race theories of civilization, although it is probable that culture is independent of race, and that changes in social structure do not depend on changes in inherited structure It would appear from studies of the distribution of intelligence in the various social groups that there is no conclusive evidence of genetic difference between the social classes A good deal of work has been done on the question whether the existing difference in fertility among various social groups is likely to affect the inborn constitution of the stock Since the differences between the groups are not genetic, the dangers of deterioration on this score are not great There is no reason to believe that the lower social grades are being drained of ability through the operation of the social ladder Studies of social mobility lead to the conclusion that conditions making for greater mobility would also make for greater equality in the distribution of wealth, and differential fertility, so far as it is conditioned by varying standards of life, would tend to disappear A social system which is based on justice and equity would, on the hypothesis of genetic differences, be the most eugenic of agencies

The subject of social stratification has recently attracted attention widely It is now possible to give estimates of the proportions of the social classes in the different European countries The proportion of middle class in Germany is about 34 per cent of the occupied population, in France about 40 per cent, and in England about 25 per cent, though these figures are not comparable, owing among other things to the differences in the number of peasant proprietors in these countries, while in England since 1881 the ratio of increases of the middle class is placed by Prof Bowley at 100 195, as against an estimate of the ratio of increases of the working classes of 100 168—an interesting commentary on the theory sometimes urged that the middle class is in process of elimination An interesting result of recent studies in social mobility is the relatively caste like character of the higher ranges in the world of business In Germany, in the main, big industrialists, big business leaders, and big landowners are self recruited, while in America, too, big business is increasingly self-recruited, and tends to become caste like, the self-made man now being rare It is generally recognized that one of the major sources of instability in modern democracy is to be found in group conflicts represented in the multiplication of political parties and in the drastic measures taken in authoritarian countries to abolish all parties save one The position of the middle classes is of special importance in this connexion as is the whole problem of occupational restratification, which has evidently been going on in Europe since the Great War

Social Control The sociology of social control is at bottom part of the sociology of social structure, since clearly a great deal of the structure of society consists in the norms regulating and controlling behaviour in law, morals, religion conventions and fashion To the sociologist, the most important types of problem are the differentiating characters of the norms the conditions under which they arise, and their influence on social conditions and on one another while important psychological problems are connected with all

There are many who think that the chief difficulties that confront the modern world in the effort to bring about some form of unity among classes and peoples are due to different valuations that are found among them Others hold, on the contrary, that with regard to the fundamental ends of life there is general agreement, and that the clash of contradictory opinions relates rather to the means which have to be adopted in order to attain these ends It is surely of the greatest importance to ascertain wherein the difference really arises, and this is not possible without a careful study of the actual beliefs and behaviour of individuals and groups, and a careful discrimination of the factual from the valuational components of moral judgements

Social Process In evolutionary sociology, among points which appear important are First, that sociologists have not yet succeeded in establishing any general laws of social evolution, though this is not to say that significant trends do not occur There has been, for example, an enormous process of unification, including increase in the size of political aggregates and in intercommunication and interdependence, political and economic, and possibly, despite cultural diversity, an underlying assimilation, or convergence, in science, art, religion, and culture Secondly, there is an increase in the command of the conditions of life, intensified by increasing knowledge of Nature, including mind and society Thirdly, various experiments have been made in reconciling order with freedom, and there has emerged in the consciousness of man the sense of the unity of mankind and the need for reconciling the requirements of order and liberty on a world scale Fourthly, if development has occurred in the history of humanity, it has certainly not been automatic or rectilinear, and its continuance in a given direction is not secured Fifthly, if development has occurred, it has been uneven, and advance in one direction has often constituted a hindrance to advance in others

Increase in the scale of organization has often been achieved at the cost of freedom, and collective efficiency may result in stultifying and thwarting the deepest needs of individuals The growth of knowledge and the command over the conditions of life has also been extremely uneven. Our powers over inorganic Nature are much greater than our powers over life, mind and society, and since the former may be used for purposes of destruction there is danger that before mankind has acquired sufficient knowledge of the causes of social change and sufficient moral wisdom to use it aright the whole structure may be wrecked and the work of organizing mankind may have to be begun all over again. Scale of organization is of especial importance at the present time.

---

* Substance of a paper by Prof M Ginsberg to Section F (Economics) at the Cambridge meeting of the British Association read on August 19, 1938

Self development even on the part of large communities is becoming more difficult and precarious. This infinitely complicates the problem of reconciling order with freedom. Both logical and historical analysis suggest that efficient control over the forces of external Nature and of the inner nature of man must rest upon an organization on a world scale and must rely on methods which can call forth the spontaneous responses of all its members in the service of ends they can recognize as common.

Social Pathology This brings out the complexity of social causation and the importance of bringing together the results of different modes of investigating and interpreting social phenomena. Taking one example only the study of cause of crime has to be approached by way of broad social and economic studies, such as (1) correlating various types of crime with social and economic variables such as price rate of commodities, density of population, rural and urban conditions of life, etc, (2) genetic studies and (3) individual case study, to which belong therapeutic methods of psychopathology. So little has been done to view the facts in relation one to another that at different times undue prominence has been given to one or other factor in the causation of crime. To the sociologist taking a broad view it is clear that no invariant relation can be established between any single factor and crime while these factors in themselves are complex and by no means independent. There are signs that the sociological method of approach is beginning to influence the study of crime both in Great Britain and in the United States.

Agricultural Research in India*

THE Imperial Council of Agricultural Research was set up as a result of the Royal Commission on Agriculture in India in 1926. One of the conditions laid down was that the Council's activities should be periodically reviewed by some disinterested expert, and in 1936 Sir John Russell was invited to make an extensive tour of the provinces with this end in view in so far as plant industry was concerned.

Sir John's report has now been published. The volume is divided into two parts, the first of which describes the type of agriculture, the crops and the factors which make for improvement in their yield, the special difficulties confronting Indian agriculture and the machinery for dealing with them. In the second part of the report, the various research schemes fostered by the Council and in progress throughout the country are described in detail.

Agriculture in India is not merely an industry but also the mode of life of a large part of the population, and in consequence the scope of the Council's activities is of a far reaching nature. Village improvement is in fact an essential preliminary to any fundamental advance in agriculture. The gulf that separates the experiment stations and the few large scale farmers from the peasants, who cultivate the largest proportion of the land, needs to be bridged, and this is rendered peculiarly difficult to effect owing to the absence of the educated middle class farmers, who form such an important section of the farming community of the West.

A vast amount of pioneering work has been successfully accomplished by the Council since its formation, and the necessary extension now lies in the co-ordination of theory with practice, that is, work in the field rather than in the laboratory, increased productiveness being always the central problem. The great increase in the area under cash crops such as cotton, sugar cane and tea compared with that under food crops, is one of the most remarkable features of modern Indian agriculture, and although much progress has been made both in their production and utilization particularly in the case of sugar cane, greater co-operation with the buyers is desirable. Advances in this direction have already been made in the case of cotton and tea, as each crop has its own research station which is in touch with the appropriate buyers. Similarly, work on food crops needs to be carried out in association with nutrition experts and inquiries made into the possibilities of extending dairy husbandry and fruit and vegetable growing if diet is to be raised to a more satisfactory level.

In view of the supreme importance of water supply the establishment of a separate research institute for the study of irrigation and water relationships between soil and crops is deemed desirable. The proper unification of dry farming schemes is, of course, equally important. Questions concerning soil erosion and alkali trouble might well be dealt with by a soil conservation committee, which could also usefully collect and collate results of manurial trials and soil analyses. Similarly, matters relating to crop planning schemes and insect and fungus pests might be in the hands of a crop production committee which would provide a convenient central body for co-ordination. Special problems such as locust control, on the other hand, need their own organization, and in spite of the fact that invasions only occur sporadically, a permanent service seems eminently desirable so that immediate action may be taken when the need arises. The Imperial Agricultural Research Institute recently opened at New Delhi will, no doubt, play a specially important part in the co-ordination of the Council's schemes, and its programme be largely determined by the most pressing problems of the moment. A number of questions to which it could usefully give attention are suggested in the report.

---

* Report on the Work of the Imperial Council of Agricultural Research in Applying Science to Crop Production in India (Delhi Manager of Publications 1937)

During his tour, Sir John Russell visited more than forty experiment stations and inspected nearly ninety research schemes, in most cases discussing the work with the individual in charge The posts under the Council's schemes are of temporary nature only and a plea is made for the provision of a number of permanent appointments, to be filled gradually by selected investigators of proved ability By this means, specially experienced men would be available to deal with difficult problems at the various stations, where local resources were inadequate Such a scheme would inevitably necessitate an increase in the financial grant made to the Council, but the return in enhanced efficiency would seem to justify this

Much of the research in agricultural science in India is not so widely known as it deserves to be, due largely to the practice of publishing results in a number of small communications The preparation of a series of monographs by competent persons is suggested, setting forth the results obtained by Indian workers and pointing out how they differ from those obtained elsewhere Such publications would greatly raise the prestige of Indian research work and also prove of value to teachers and research workers throughout India itself

Radio Transmission and the Ionosphere

MARCONI'S discovery that radio waves followed the curvature of the earth indicated that the signals were reflected back to earth by an electrified condition of the upper atmosphere In 1925 Prof E V Appleton in England and Breit and Tuve of the Carnegie Institution (U S A) gave definite experimental demonstrations of the existence of such a mirror

Since these experiments were made research on the electrified region of the atmosphere, called the ionosphere, has made great progress It is now known that several distinct layers of ionization exist The first, called the E layer, is at a height of about sixty miles and is capable of reflecting fairly long waves The second called the F_1 layer, is capable of reflecting shorter waves, at a height of about 120 miles, and the third the F_2 layer, reflects still shorter waves at a height of about 180 miles The ability of these layers to reflect radio waves depends on the number of electrified particles present, either electrons or electrified air molecules In an article communicated to the *Radio Review of Australia* of June by a member of the staff of the Carnegie Institution, it is described how the ionosphere affects radio transmission

The author refers to the recent discovery by Dr J B Dellinger, of the U S Bureau of Standards, of sudden fade outs of high frequency radio signals on the daylight side of the earth, and that these fade outs were connected with the hydrogen prominences which sometimes appear on the sun It is believed that all these fade outs occur simultaneously with solar eruptions When a fade out occurs, no reflections are obtained from the E, F or F_1 layers It is just as if one were looking into a looking glass and suddenly the reflection disappeared The cloud of electrons which prevent the waves being transmitted may be considered as a 'blanket covering the entire daylight hemisphere of the earth at a height of 40–60 miles

A very pronounced fade out occurred in April 1936, a sudden brightening was observed in the region around a spot on the sun One minute later radio reflections from the ionosphere ceased and a large change also occurred in the earth's magnetism and in the earth currents The heights of the reflecting layers recorded at the Carnegie Institution's observatories in Peru and Western Australia and by other organizations, serve to indicate the nature of the effects produced.

The improved quality of the ionosphere during times of sunspot activity makes a greater range of wave lengths available for long distance transmission Unfortunately, times of sunspot maximum are most favourable for the occurrence of magnetic storms These storms are believed to be due to swarms of ions and neutral corpuscles ejected from the sun with such speed that they reach the earth in about a day Impinging on the atmosphere, these corpuscles give rise to auroral displays in high latitudes and seriously impair radio communication, when the path of the radio waves passes close to the radio zone —a region about 20 from the geo magnetic pole Most of the radio traffic between the United States and Europe traverses such a path, with the result that on days of great magnetic disturbances those radio circuits are never available

On the other hand, radio traffic between the United States and points in South America is not seriously impaired by magnetic disturbance An ingenious application of this fact was made by one of the commercial companies during the severe magnetic disturbances on April 24 28 1937 Radio messages intended for European points were routed' through the company's station in South America and retransmitted to Europe, with the result that communication was maintained throughout the disturbance

Another interesting application of scientific knowledge concerns the scheduling of trans Atlantic broadcast programmes Research has shown that times of magnetic disturbances tend to recur at 27 day intervals, corresponding to the period of rotation of the sun On this basis, it is possible to predict a month or two in advance the days that are likely to be unsatisfactory for long distance transmission and the days that are likely to be satisfactory International broadcasts, scheduled for pick up by one of the large networks, are arranged so far as possible to come when no magnetic storms are expected

The means by which magnetic storms affect radio transmission is not clearly understood The effects of magnetic storms on radio transmission are markedly different from the effects produced by the ultra violet light from solar prominences While storm effects are most strongly manifested in high latitudes, the fade outs are most pronounced near the equator Furthermore, the fade outs occur only during daylight hours, while the storms disturb radio transmission on both the day and the night sides of the earth

Acid and Basic Open-Hearth Steel-making Practice

THE annual meeting of the Iron and Steel Institute held on May 4–6 was devoted to a general discussion of open-hearth steel-making practice. A very large amount of data was brought together from all of the main steel-producing areas of the British Isles, and this material is most excellently summarized. As a result, it has been possible to determine in a manner hitherto impracticable the main factors on which high furnace efficiency depends.

It is confirmed that, within the working limits imposed by the refractory materials, etc., the output of a furnace is directly proportional to the heat input. For furnaces producing ordinary commercial steels, an average of 2 lb. of steel per hour per therm may be expected in the case of fixed furnaces and 1.6 lb. for tilting furnaces. Large furnaces of the latter type show the lowest output of any of those examined, probably on account of the long period of refining required with the high percentages of hot metal employed. On the other hand, such furnaces have the advantage of a much lower consumption of refractory materials than obtains with other types of furnace.

For furnaces of normal port design, a high ratio of the velocity of the gas to the air gives the best performance, which requires that the area of the air port should be at least six times that of the gas port. Where this adequate gas/air velocity is obtained, conventional designs of the ports have given results which are as good as those obtainable with special constructions. Whilst the relative area of the hearth should be large when high proportions of scrap are being used, this factor of design is dependent on that of the ports and on the direction of the flame. On the other hand, when the percentage of hot metal is high and of high metalloid content, deeper baths are employed with correspondingly reduced areas of hearth.

The highest rates of production are shown to be obtained from basic, hot-metal, fixed furnaces, averaging 7·53 tons per hour per 100 tons capacity, a figure which may be compared with 7·46, 6·49 and 5·78 tons per hour for basic, cold-metal fixed; acid cold-metal fixed; and basic hot-metal tilting furnaces respectively. They have, however, a higher average total heat consumption per ton of 86·2 therms as compared with averages of 82·8, 84·6 and 76·7 therms per ton for the other types.

"With our ever-increasing knowledge of the subject the physical chemistry of steelmaking has become of great importance in the operations of steel manufacture, and there are few sections of the industry to-day which have not benefited from the wider appreciation of the possibilities of this branch of applied science." Thus Dr. McCance introduces his paper on the application of physical chemistry to steel-making, in which he surveys the work done by himself and others in Great Britain, the United States and Germany. Starting with a general discussion of the basis on which this work has been built, the paper proceeds to direct attention to the more important conclusions already reached which have a direct bearing on the practice of steel-making by the open-hearth processes. The reduction of oxides by carbon, the manganese and silicon reactions; the reduction of manganous oxide by silicon, the reactions due to sulphur compounds and those in which phosphorus are involved are considered in turn, together with the question of ingot cracking.

Although the paper is unsuitable for further condensation here, it may be said without fear of contradiction that it represents the most substantial attempt ever made to consider any process of metallurgical production on a really scientific basis.

F. C. T.

Scientific and Industrial Research in Canada

THE twentieth annual report of the National Research Council, Canada, covering the year 1936–1937[*], contains the report of the president of the Council as well as reports from the various divisions. Even the president's brief review of the organization of research, both pure and industrial, indicates that the work of the Council makes contributions to the progress of industry in Canada comparable with the contribution of the Department of Scientific and Industrial Research in Great Britain. The Division of Biology and Agriculture is devoting considerable attention to studies in the storage and transport of food. Valuable information obtained by visits to Europe during the year is being applied to the improvement of export trade arrangements. Simple and rapid methods have been worked out by the Division for determining the probable effectiveness of weed killers by their effect on the rate of growth of plants in water culture. A new method of experimental malting has been developed which seems to give the true value of varieties of barley, even though these require widely different malting conditions to give the best results. A new paper box packing has been developed for storing and shipping poultry, which can be sealed conveniently to prevent loss of moisture and the danger of freezer-burn. Apparatus has been developed for accurate measurement of atmospheric humidity at low temperatures and when only small amounts of moisture are present in the air. Work has been carried out on the relation of bacteria to the curing and to the uniformity of cured bacon, and other work has been carried out by the Division on the baking quality of wheat and in co-operation with the Canadian National Railways on a method of heating refrigerator cars which has led to the development of an underslung charcoal heater.

The Division of Chemistry has developed a relatively cheap synthesis for α-naphthylacetic acid as well as methods for the synthesis of indolyl-butyric acid and indolyl-acetic acid. A fundamental study is being made of the problem of corrosion, and further work has been carried out on the novel form of distillation, which was invented by the Division, arrangements having been made for the manufacture of the gauze packing Research on plastic casein has also been undertaken and research on the preparation and properties of carbon black from waste gases from the pyrolysis of natural gas has been concluded, while further work has been carried out on the preparation of carbon black by the channel process Work on the use of formalin for the disinfection of seed wheat has been extended to include the study of many organic compounds as seed disinfectants Good progress is reported in work on the fundamental laundrying operation bleaching, as well as in work on the fading of dyed textiles in sunlight, determination of damage to silk by a viscosity method and the regain of raw wool

---

[*] Twentieth Annual Report of the National Research Council, 1936–1937. Pp. 182. (Ottawa: National Research Council of Canada, 1938.) 75 cents.

In the Division of Mechanical Engineering, the Aerodynamic Laboratory has carried out tests on models of three service aircraft in the wind tunnel to prove the accuracy of prediction of the performance of aircraft from the results of wind tunnel tests Comprehensive wind tunnel tests have also been made for a Canadian aircraft building firm in connexion with the development of an aeroplane being designed specifically for commercial service in Canada Measurement of hydrodynamic forces on stop logs for emergency dams in ship canals was a new and interesting study commenced during the year Other problems under investigation include the work on fire hazard testing farm windmills, gasolene specifications aircraft instruments and the inspection and labelling of oil burners The Division of Physics and Electrical Engineering has undertaken fundamental work on light, sound, heat and electricity as well as standardization in these and in related fields The development of an improved and highly satisfactory means of heating refrigerator cars in winter which makes it possible to maintain uniform temperatures in the cars is now being taken up commercially Studies in heat transfer are being applied to the tests in insulating material and to the investigation of heat conservation qualities of textiles used for clothing Tests are also being made to determine the sound absorptive properties of building materials and the proper design of rooms for the best acoustical effects Other experiments have been concerned with electrical methods of packing poultry in preparation for marketing A second cathode ray direction finder was built during the summer and a development programme to adapt this type of radio direction finder to commercial service has been undertaken

In addition to the work of the various Divisions, important work has been carried out through the joint or associate committees, including research on the breeding of rapid growing rust resistant strains of wheat, oil seeds research, feeding stuffs research, investigations on seed treatment with formaldehyde, on the effect of environmental factors on wool, on deficiency diseases of sheep, on asbestos, etc The Associate Committee of Parasitology has been responsible for studies of liver fluke disease, warble fly eradication anthelmintics etc

---

Explorations of the Smithsonian Institution, 1937

IN the annual review of the research activities in the field of the Smithsonian Institution, Washington, D C (*Explorations and Field Work of the Smithsonian Institution in 1937*' Pp 122), a preliminary announcement is made of the results of twenty four expeditions, for the most part in geology, biology and anthropology Some of these were financed wholly by the Institution, others were cooperative undertakings with institutions interested in the promotion of those respective branches of science Most of the expeditions in 1937 were within the American continent, including the West Indies Of the expeditions to other continental areas, Mr H G Deignan describes an exploring expedition to Siam for the purpose of observing and collecting specimens of the fauna

An expedition to the East Indies in conjunction with the National Geographic Society led by Dr W M Mann visited Sumatra, Amboina, the New Guinea coast, Java, and Singapore, collecting living animals, birds and reptiles for the National Zoological Park The minerals of Russia were investigated by Mr E P Henderson, who visited the Kola Peninsula before attending the International Geological Congress at Moscow The American expeditions and investigations included catching walrus pups in Greenland and moose hunting in Alaska, collecting insects in the West Indies and Virginia, fossils in Michigan, Utah, Arizona and elsewhere, and studies of the Montagnais-Naskapi Indians of the St Lawrence river

Among the archæological investigations an account is given by Mr David I Bushnell, jun, of an ancient site on the banks of the Rapahannock in Virginia, exposed by flood water in the early months of 1937, which produced stone implements of varied types and pottery bearing the impression of coiled basketry, considered to be the oldest form of pottery found in the Rapahannock valley Other village sites of a similar character and exposed by the same agency, were visited, which suggest that much instructive evidence would be obtained by systematic excavation Further investigations on the Lindenmeier stone age habitation site in northern Colorado have produced evidence of importance relating to Folsom man, though the skeletal remains of this early type of man in America still evade search Dr F H H Roberts, jun, who describes the results of his investigations here in 1937, records the discovery of a number of anvil stones still *in situ*, on which Folsom man manufactured his implements and cracked bones for marrow, as is shown by the fragments of various kinds of stone and bone found in the surrounding ground The stratified deposits show that the site was occupied after the climax of the Wisconsin period, but within the late Glacial, when a colder and moister climate, which was responsible for the heavy soil zone overlying the evidence of occupation, was approaching Dr Aleš Hrdlička adds details relating to his investigations in the Aleutian islands of the problem of the migration of early man into America further to those already reported (see NATURE, 140, 577)

Methods of Using the Theodolite

Before the Society of Arts for Scotland, on November 28, 1838, Edward Sang, a civil engineer and machine maker of Edinburgh, read a Notice of an Erroneous Method of using the Theodolite with a Strict Analysis of Various Arrangement of Readers When conversing with one who had been engaged on the Ordnance Survey, Sang learned of a peculiar arrangement of the readers which existed in some of the instruments used Expressing the opinion that the method was erroneous, he developed an analysis and submitted it that it might help to remove that blind reliance on the authority of names which was too prevalent The errors, he said, would not visibly affect maps of counties but they were high enough to render inaccurate determinations of the degree of meridian In the course of his paper he said Mere opinion has too long held the place of accurate study in the construction of angular instruments In particular, the question whether the method of repetition or that of frequent readings, be preferable, had been discussed with almost national warmth Repeated observations were French single observations were English, as if there be national scientific creeds

The Botanical Society

At the anniversary meeting of the Botanical Society, held on November 29 1838, the report of the council showed that 48 members had been elected since the last anniversary and the total number was 98 The number of British plants received amounted to 18 592 specimens including 1,050 species The foreign plants received amounted to about 10,000 specimens including about 4,000 species The distribution of British plants, it was stated, would take place in January, when each member would receive such of his desiderata as were in the herbarium, in proportion to his contribution

The Royal Society

At the anniversary meeting of the Royal Society on November 30, 1838, the Marquis of Northampton was elected president, while Sir John William Lubbock was elected treasurer, Roget and Christie, secretaries and Capt W H Smyth, foreign secretary The Copley Medal was awarded to Faraday, the Rumford Medal to J D Forbes, and the Royal Medals to H Fox Talbot and Thomas Graham

Macroscelides

'The curious insectivorous mammal called macroscelides,' said the *Athenæum* of December 1, 1838, "which inhabits the rocky mountains of the western part of the district of Algeria, has recently been observed by M Wagner It inhabits the crevices of rocks, and makes its bed in the underwood of the dwarf palm, it eats the larvæ of insects, grasshoppers and terrestrial mollusca, introducing its rostrum into the snail shells before the animal has time to retreat It is remarkably gentle, only expressing uneasiness by a low sound, something like a sigh It raises itself on its hind legs when it hears any sudden noise, and also leaps upon its prey, but never walks solely on two legs like the Jerbra It disappears in the rainy season and during the great heat"

The Scientific Approach to Modern Life

THE spirited address in defence of modern youth which Lord Tweedsmuir delivered on his installation as chancellor of the University of Edinburgh in July last has much to commend it to the attention of scientific workers In describing the functions of a university he added one more to the many voices warning us to day that we must zealously defend the freedom and the integrity of our thought boldly facing new conditions ready to meet every problem shirking no difficulty but rigid in our fidelity to the laws which govern our intellectual being

A university Lord Tweedsmuir asserted must transmit and advance knowledge It is not only a seminary for the training of youth but also a museum for record a laboratory for discovery and a power house for inspiration Those duties are closely united for without a centre of creative thought behind them the professions for which the university trains youth will become stagnant and blind

The maintenance of the delicate structure which we call civilization in the face of the destructive forces at work in the world to day is a task to which the university must make an indispensable contribution That task is not rendered the easier by any retreat to the older philosophies Even if we can select one of the older systems as the basis of all learning it is no simple matter to link it up with the multitudinous activities of the modern world, the study of the physical universe and of the infinite ramifications of human society To select arbitrarily a set of first principles and to make all studies subordinate to them is in effect as Lord Tweedsmuir pointed out to establish an intellectual dictatorship and to kill the freedom of the mind

Significantly enough Lord Tweedsmuir suggested that we should aim at giving our youth minds accustomed to think and inspired by a reverence for thought At the same time they must have the perspective created by some understanding of our long human story Only thus can we endow them with what is most needed —confidence and hope He went on to urge the claims of scientific research as a career whether in the service of the universities or industry or of the State Such a career he said offers a life of perpetual adventure and in that field every university can do useful work

There is indeed ample room for the spirit of adventure to day and for the discipline behind it which makes adventure fruitful Conceived in this way scientific research offers a great opportunity for it becomes linked to the development of personality and the exploration and recognition of human values The great and enduring human values inherent in our democratic institutions cannot be maintained by trying to stabilize the machinery through which they find expression They can only be defended by being made to work effectively and unless we can modify our institutions in line with the profound changes in the complexity and conditions of government they may well perish

Here as Major L Urwick suggested in a recent stimulating paper published in the *British Management Review* on Administration and Society is one of the challenges thrown down to modern youth research into the human and social aspects of administration and government which will yield the scientific knowledge by which we can bring mechanization under control and adjust accurately our social organization The ideals and experiments outlined by E Mayo in Human Problems of an Industrial Civilization (New York The Macmillan Co 1933) or T N Whitehead in Leadership in a Free Society (Oxford University Press) are only beginnings but are pregnant with possibility

It is indeed the neglect in the past of human purpose psychological factors and social factors by industry that leads Gillespie in his recent book The Principles of Rational Industrial Management (London Sir Isaac Pitman and Sons Ltd 1938) to reject the whole term scientific management for some of the protagonists and practitioners have undoubtedly been prone to overlook the limitations of science in management Scientific method is only a tool of management It is not the whole of management and is not a substitute for personal values Moreover as Gillespie points out not only has the social purpose of industry been neglected and its social responsibilities overlooked but also management has often failed to recognize the significance of its own obedience to the purpose which industry is serving It is a sound principle that one of the first steps in training for leadership is learning to obey and management has often failed in obedience to its own rules and precepts and to the full purpose which industry should serve

Conceived on these lines we need not fear that democratic institutions cannot be moulded by youth to meet the challenge of to day The problem of freedom once more a cause to fight for is encountered everywhere no less in industrial than in national life No less in the industrial unit than in the nation the first condition of freedom is stability and a sense of justice inspiring the loyalty which accepts not discipline so much as self discipline and the co operation and good will for free service in a common aim

This is essentially the moral rearmament of which Sir William Bragg spoke in a recent broadcast address Only the vision and inspiration of a great and noble purpose can suffice to rally youth to the task not of service in the sense of defence only but of building a new world order in which every individual and every community may find full opportunity for self expression and development and in which the national defences now being so hurriedly erected can be made unnecessary This task demands much patient and painstaking research It involves a wide vision and wise judgment in the direction of such research and the reorientation of such effort as well as the institution of research in fields yet largely untouched It demands too the free acceptance of discipline and loyalty to the idea of service and a capacity to evaluate all the issues to see life steadily and to see it whole which should appeal to all that is best in youth and command its steadfast allegiance and noblest endeavours no less than the daring and fortitude to which Lord Tweedsmuir paid tribute Lord Tweedsmuir's address has earned the gratitude of all scientific workers whether of the younger or of the older generations no less for the clarity with which he has defined the challenge than for the inspiration with which it summons them to seize the opportunities which lie beyond that challenge

International Co-operation in Geology

Lexicon de Stratigraphie
Vol 1 Africa Edited by Dr S H Haughton Pp vi+432 (London Thomas Murby and Co 1938) 31*s* 6*d* net

A COMMISSION elected at the fifteenth meeting of the International Geological Congress assembled at Pretoria in 1929 decided to produce a Lexicon de Stratigraphie with a volume devoted to each continent in turn The general editorship was entrusted to Dr S H Haughton who has naturally started with Africa

The purpose of each volume is to furnish definitions of all stratigraphical terms that have appeared in the geological literature of the particular continent and to arrange them for convenience of reference in alphabetical order The definitions must be accompanied by appropriate references and must indicate past and present meanings Thus in the case of a formation of local origin the original meaning is cited along with the more significant of subsequent changes Comments are added regarding geographical and geological relations the whole of course in brief dictionary style

In the present volume Dr Haughton has been assisted by twenty three collaborators whose contributions are duly initialled Most of them have written in English or French a few in Italian

In the text the stratigraphical unit is used as the main heading under which detail is subdivided according to country In the index this arrangement is reversed— a very convenient device

There are more than 1 100 stratigraphical headings in the course of 419 pages Groups of systems such as Palaeozoic are not mentioned but from systems downwards any unit seems to have been acceptable At the same time there are very few in the list which owe their name to a fossil Thus though the *Nummulites gizehensis* Beds and the *Tapinocephalus* Zone occur in their alphabetical position one must look up Cénomanien to find mention of the Zone à *Acanthoceras rotomagense* and Aalénien for the Zone à *Harpoceras murchisonae*

Obviously the treatment is uneven this however is not only unavoidable but also within limits desirable The result is extremely valuable and definitely intriguing One is led on from page to page among unfamiliar names or names with unfamiliar associations The Chiwondo Beds one learns along with much other information have *Cleopatra* among their characteristic molluscs the Variegated Marls defined in 1900 occur in the lower part of the Uitenhage Series and in 1928 have been classed with the Wood Beds Taking the volume as a whole the best comparison perhaps that can be made among geological utilities is with Holmes's Nomenclature of Petrology

This lexicon should certainly be added to every important library that deals with the pure or applied aspects of geology It represents one of the many benefits which have been derived from the International Geological Congress British geologists now await instructions from Dr Haughton before starting on their share of the European volume which we may hope— will appear in separate parts We want to be able to report good progress when the Congress meets in London in 1940

L B BAILEY

The Negro in the United States

The Negro's Struggle for Survival
a Study in Human Ecology By Prof S J Holmes Pp xii + 296 (Berkeley Calif University of California Press London Cambridge University Press 1937) 13s 6d net

THROUGHOUT Nature the struggle for existence is usually an orderly and peaceful process and it may not be possible to explain in simple terms just why one species succeeds in supplanting another Only occasionally even in the animal world can such replacement be attributed to superiority in open conflict In the history of man too it has been the bloodless battles in times of peace between obscure biological forces affecting the balance of births and deaths which have generally proved more decisive than wars in deciding which peoples shall survive and which shall disappear This aspect of human evolution is emphasized and well illustrated by Prof S J Holmes in his thoughtful examination of the vital statistics of the Negro in America

The white man's impact on primitive peoples has often been deadly in its results In his explorations he has inadvertently taken with him the scourges of measles influenza pneumonia and tuberculosis In his civilizing mission he has introduced the curses of alcohol venereal disease and clothes Some native populations such as those of Tasmania and Australia have in consequence given up the struggle for survival whilst others as in the Pacific Islands have been threatened with extinction In some parts of the world the Negro peoples have been able fortunately to survive the devastations of their first contact with the white race They have thus been able to reap some of the benefits of improved hygiene the prevention of tribal wars and the saving of infant life but now they are faced with a more insidious threat to their future welfare in the fall of their reproduction rate It is mainly with this problem of the balance of births over deaths amongst the Negro population of the United States of America that Prof Holmes deals

Under slavery most Negroes were employed on farms and plantations of the southern States and their health was relatively good but the Civil War changed this The terrible conditions of the Negro's first decade of freedom brought in their train a great increase in tuberculosis syphilis malaria pellagra and other debilitating diseases The records of the cities indicate that the Negro death rate continued to rise for nearly a quarter of a century after the Civil War but notwithstanding an infant mortality which carried away every third or fourth child their high fertility still enabled the Negro population to increase The first decades of this century witnessed a rapid fall in their mortality but the effects of this were offset by a falling fertility amongst those who took to town life Urban life is not so well tolerated by the Negro as by the white the advantages of a relative immunity to some infections such as scarlet fever diphtheria and erysipelas being more than counterbalanced by a greater liability to bronchitis pneumonia and other diseases of towns The great trek of 1917 18 to the cities of the north which resulted from restriction of alien immigration therefore exacted at first a heavy toll on the balance of births over deaths but the adjustment was made

At present according to all available measures of fertility the Negro women are reproducing more rapidly than the white women in the United States and taking into account their greater death rate Prof Holmes concludes that there is at the moment a neck and neck race with a fair prospect that the Negro may soon be increasing at the faster pace This depends on many uncertainties such as the increasing use of contraceptives in rural communities and the conquest of the scourge of venereal disease It is a problem which will engage the attention of students of population and eventually of administrators to an increasing degree and Prof Holmes has rendered no small service by gathering together such a wealth of statistical material and interpreting it with such commendable caution P S

Early French Men of Science

Figures de Savants
Tome 3 l Académie des Sciences et l Étude de la France d Outre Mer de la Fin du XVII Siecle au Début du XIX^e 1 Antilles et Guyane Par Alfred Lacroix Pp xiii + 220 + 38 plates 125 francs Tome 4 l Académie des Sciences et l Étude de la France d Outre Mer de la Fin du XVII Siecle au Début du XIX 2 Mascareignes Madagascar Inde Indochine Pacifique Par Alfred Lacroix Pp iv + 259 + 59 plates 150 francs (Paris Gauthier Villars 1938)

IN these two well illustrated volumes the permanent secretary of the Paris Academy of Sciences has collected a very useful and instructive series of short notices of the distinguished French men who promoted the cause of science in the French Empire during the later part of the seventeenth and the eighteenth centuries The Academy itself of which M Lacroix gives a short account had during the seventeenth century no permanent home It received help from Colbert who was always prepared to further French colonial interests and it was finally installed in the Louvre by the King in January 1699

In these volumes the men of science dealt with appear under a geographical arrangement Vol 3 contains notices of those working in the West Indies Guiana the Mascarene Islands Madagascar India and Indo China The last four countries are again represented in vol 4 together with West Africa A separate section in this volume is devoted to the family of Jussieu five of whom were distinguished naturalists The volume ends with a plea for some central organization to deal with research at the present day

It is not possible in a short space to give an adequate idea of the wealth of information which M Lacroix has collected in these four hundred and fifty pages The particular interest of the Academy in astronomy and physics is represented for example by Jean Richer s mission to Guiana in 1666 and by a similar mission of La Condamine in Peru and Guiana Richer s work on gravity was of outstanding importance Similarly we have a picture of Peyssonnel and his work on the polyps begun in the Mediterranean and completed in Guadaloupe He received little recognition at the time in France but his work was published by the Royal Society and he was made a foreign member Bouvet better known as the discoverer of a small island to the south of Africa is shown in these pages as the patron of Poivre who did valuable work on spices Two other notable explorers Kerguélen and Lapérouse appear in a more familiar setting Sir Joseph Banks is mentioned several times His intervention secured the return to France of the botanical collections of La Billardière after their capture by the Dutch Some interesting correspondence on this matter and on the question of Sir Joseph s failure to secure election to the Academy and a similar failure of Jussieu to secure election to the Royal Society is reproduced

The omission to index a reproduction of a letter of Jussieu to the Minister of Police has made the references to the portrait of Banks (Pl xlviii) and a facsimile reproduction of his letter to Delambre (Pl xlix) and of subsequent plates incorrect while the numbering twice over of Plate xxxix in the Explication des Planches has thrown all subsequent references therein wrong But these are trifling inconveniences in a work which is full of illuminating if disjointed appreciations of the great men of science of France J N L B

Stellar Physics

Physik der Sternatmospharen
mit besonderer Berücksichtigung der Sonne Von Prof Dr A Unsold Pp viii + 500 (Berlin Julius Springer 1938) 66 gold marks

IT is clearly recognized how closely the rapid progress in astrophysics has been linked up with the advancement of physics since the beginning of this century Taking into account the fundamental theoretical work of Schwarzschild it would appear that astrophysics became a quantitative science only during the past thirty years The new problems arising during this period have resulted in an extensive literature the material of which has been partly collected in voluminous handbooks But what was badly needed at the present stage (especially for those who wanted to enter the new fields of research and found themselves confronted with this mass of material) was a critical and so far as possible systematic study of the subject

The present book fills this gap most happily The author is a distinguished astrophysicist whose own contributions to science are of fundamental importance His theoretical work shows a rare insight into the conditions of observational astrophysics and into its limitations It is significant also that in his present book Unsold resists all temptations to follow up theoretical developments for their own sake He succeeds very frequently in re presenting theories in a new and simplified form This and the great care he takes to deal with the observational material available make his book readable and useful both for the theoretical and for the practical workers in the field

The volume consists of five parts The first one on more general lines serves as a kind of introduction to the detailed treatment of the later chapters After a brief review of the physical theory of radiation the author deals with general problems of solar and stellar radiation such as the solar constant and the effective temperature of the sun brightness and colour temperature of stars A chapter deals with Saha's formula and its application to stellar atmospheres and gives a survey of its limitations

Turning to the second part of the book we are given a thorough analysis of stellar atmospheres and of their radiation so far as the continuous spectrum is concerned Naturally the theory of radiative equilibrium is treated in all important details The law of darkening towards the limb, and its dependence on wave length, are other topics contained in this chapter the second and main part of which is devoted to the continuous absorption coefficient Introducing Rosseland's mean value κ the author develops the physical theory of the continuous absorption coefficient describes the experimental tests of its validity and applies finally the results obtained to solve the problem of the energy distribution in the continuous spectrum of the stars

From the discussion of the continuous spectrum the author passes to the vast realm of the absorption lines to which naturally the major part of the book is devoted The introductory third part gives an account of all that physics knows about the formation of absorption lines Here we meet the classical theory of representing the atom by damped harmonic oscillators The treatment then follows on the basis of the quantum theory in which for example radiation and collision damping as well as the intermolecular Stark effect are dealt with The quantum mechanics computation of transition probabilities and oscillator strengths is given and on account of the importance of multiplets the Burger Dorgels rule is treated in a special chapter Finally the experimental side of the problem is well represented such items as the measurement of oscillator strengths experiments on the broadening by collision damping or Stark effect etc are clearly discussed

This physical interlude is followed in the fourth part by the treatment of the fundamental problem of the Fraunhofer lines the absorption lines of astrophysics After a brief survey of observational questions which is very useful for the beginner we find here the necessary extension of the theory of radiative equilibrium given in preceding chapters so as to include line radiation The well known Schuster Schwarzschild and Milne Eddington models and their generalizations are dealt with in detail It is shown that the main problem in the theory of the Fraunhofer lines is to find from measurement of the intensity of the line the number of absorbing atoms The author gives the corresponding relations on the basis that the broadening of a line is mainly due to the Doppler effect and to damping The influence of these effects and especially of the second one in stellar atmospheres is shown as well as the importance of the intramolecular Stark effect for the hydrogen lines In this same chapter the theory of central intensity, the role of interlocking and the problems of the blends are treated The study of outside factors causing broadening such as rotation, or expansion of a stellar atmosphere, concludes this most interesting section

The beginning of the fifth and last part of Unsold s book is devoted to the applications of the theory of Fraunhofer lines to the problems of spectral classification and to a quantitative analysis of the solar atmosphere The last two chapters deal with the outer layers of the sun Here we find first of all studies on sunspots faculæ and granulation (an example of the role of convection in stellar atmospheres) and further an account of our physical knowledge of prominences the chromosphere and the corona

The work is concluded by a well arranged bibliography which comprises no fewer than 1 800 entries

A review of this unique book can only give an outline of its contents and its purpose The author has fulfilled his intentions in an admirable way and his work is likely to prove indispensable to all workers in astrophysical and related fields It fills a real gap in astronomical literature in which we were lucky enough to welcome some time ago Rosseland s Theoretical Astrophysics treated on quite different lines (see NATURE 138 628 1936) Prof Unsold has rendered a great service to astronomers as well as to physicists who will be glad to make use of the fundamental problems and their solutions arising from a study of those great physical laboratories the stars A B.

The Liberal Arts Applied to Modern Medicine

The Doctrine of Signatures
a Defence of Theory in Medicine By Scott Buchanan (International Library of Psychology Philosophy and Scientific Method) Pp xv + 205 + 20 (London Kegan Paul and Co Ltd 1938) 7*s* 6*d* net

IN the form of a plea for renewed freedom of speculation in thought Prof Buchanan has written a very interesting book in which he is not concerned with social and political restraints but with the far more stultifying hesitations in the minds of thinkers of the present time He is alarmed to find all around him evidence of the fact that the intellectual process is being called in question and its consequences feared As subject matter for investigation Prof Buchanan has chosen the science and profession of medicine which throughout European history has always fought and won the battle for freedom of thought but which now that it is in possession of victory, stands hesitating at the head of the sciences burning with intellectual energy and imagination but not knowing which way to go In Prof Buchanan s opinion modern medicine is suffering from a lack of balance of the intellectual virtues and while it has a maximum of informatory knowledge has a minimum of understanding

For this unhappy state of affairs Prof Buchanan prescribes two remedies which he maintains are forgotten rather than new These are the use of symbols and of demonstration—or in other words the application of the liberal arts—the trivium and the quadrivium to medical education Here the patient becomes a text to be read and translated according to the rules of medical grammar For according to the doctrine of signatures medical knowledge consists of seeing the connexions between symptoms and remedies and the liberal arts are concerned with signs and symbols and also with the levels of generality and abstraction that appear when symbols are used Prof Buchanan accuses modern scientific medicine of elaborate empiricism and anti intellectualism and thinks that the doctrine of signatures and the liberal arts would be good exercise for our weak symbolic faculties Furthermore he alleges that the disuse of demonstration in the biological and medical sciences has tended to atrophy the understanding and proceeds to show how Plato Aristotle and Galen discovered and established the demonstrative power of form and matter in biological science He thinks that its re discovery and re establishment would both revive and direct our stultified speculative energies

There is no doubt that Aristotle and Galen represent the peak of Greek medical science but Prof Buchanan maintains that to day we are only working out the details of their fundamental insights To support this view he states that students of the history of medicine are repeatedly disclosing the fact that the greatest of original modern discoveries in physiology and anatomy are but the discoveries of ideas and illustrations of principles in the Aristotelian and Galenic works While he would not go so far as to say that there is nothing new in science he assures us that we have yet to recognize the science which has made possible such novelty as there is We should try to recover the doctrines of the tradition from which modern developments have grown in the hope that they may be rendered intelligible enough to absorb modern science within the borders of their ancient wisdom

The subject is certainly a fascinating one and Prof Buchanan's treatment of it although necessarily rather fragmentary in a book of this length is both stimulating and disturbing

Plant Physiology

By Prof Nicolai A Maximov Edited by R B Harvey and A E Murneek (McGraw Hill Publications in the Botanical Sciences) Second English edition, translated and revised from the fifth Russian edition Translated from the Russian by Dr Irene V Krassovsky Pp xxii +473 (New York and London McGraw Hill Book Co Inc 1938) 25s

NICOLAI MAXIMOV is a plant physiologist with a world wide reputation, especially in connexion with the water and soil relations of the plant, and this alone justifies a translation from the Russian of any work of his even if it is only a survey of the subject for the benefit of the student In spite of the fact that there are now several good text books on plant physiology in English written by British and American authors, one by this well known Russian who is an active worker and prolific writer is bound to bring a certain freshness of outlook so that it may be regarded as a valuable supplement to any text book which the student is already using

This second English edition has been translated from the fifth Russian edition, which was so completely rewritten by Prof Maximov as to warrant a new title (The first edition was entitled Textbook of Plant Physiology) It should be pointed out, however that Prof Maximov s researches are biased towards plants of agricultural importance, and thus this book deals as he terms it, more with "agro physiology than with general plant physiology Thus the physiology of saprophytes, parasites, bacteria, fungi and algæ is scarcely considered The book can therefore be strongly recommended as a text book to students of agriculture and as a supplementary book to students of general botany, since its economic outlook will certainly give added interest to their studies

The subject matter is considered in the orthodox manner under such headings as physico chemical organization and chemical composition of the plant, respiration, growth photosynthesis, nitrogen assimilation, absorption of mineral elements, water relations, translocation and so forth Certain subjects such as growth, development and seasonal phenomena receive fuller and better treatment here than in most books on the subject The book deserves unqualified success

A Text-Book of Biochemistry

for Students of Medicine and Science By Prof A T Cameron (Churchill's Empire Series) Fifth edition Pp viii+414 (London J and A Churchill, Ltd , 1938) 15s

THE fourth edition of this very successful text book was reviewed in NATURE of January 6, 1934, p 8 There have been a total of ten editions and reprintings since the original publication of the book ten years ago, so there can be no questioning its utility, especially to medical students, to whom it is primarily addressed

Any text-book dealing with such a progressive subject as biochemistry is naturally bound to become quickly out of date in parts, so the success of this work is of particular value in offering the author opportunity of revision in the light of recent research The author has availed himself of the opportunity with the result that this new edition has been almost completely rewritten The subject matter has also been rearranged As in the previous edition the author has assumed a basic knowledge of organic chemistry but justifiably opens with a résumé of the concepts of physical chemistry Thence the student is brought directly into contact with biochemical agencies —enzymes hormones and vitamins Here the subject matter has been severely curtailed apparently to satisfy the immediate needs of the medical student Phytohormones, as such are dismissed in one sentence though certain of them such as indole acetic acid indole propionic acid, skatole etc , are considered further on in the book in connexion with the action of intestinal bacteria

The chapters on the biochemistry of the foodstuffs leave nothing to be desired We are glad to note that the author has corrected a previous error and here states correctly that strophanthin hydrolyses to glucose, cymarose and strophanthidin

The rest of the book deals with those branches of biochemistry essential to students of medicine, and concludes with a consideration of pharmacology and of immunochemistry and the chemistry of filterable viruses The book is a pattern of compression , in fact to survey such a wide subject in four hundred pages so satisfactorily is a feat of which the author may well be proud

Icones Plantarum Sinicarum

Fascicle 5 Edited by Hsen Hsu Hu and Woon Young Chun Pp iv +50 +plates 201–250 (Peiping Fan Memorial Institute of Biology, 1937)

THE publication of fascicle 5 of the Icones Plantarum Sinicarum brings the total of plates published in this work to two hundred and fifty The illustrations are in black and white, most plates include analyses and many show both flowers and fruits One species is figured on each plate and described in the text in English and Chinese Nearly all the subjects are woody plants (only five herbs have been figured so far), and the large size of the plates (the work is a folio) is a great advantage in that it allows ample material of the plants to be illustrated The value of the work is enhanced by the fact that many of the plants figured, especially in fascicles 3–5 are species described in recent years, whilst another valuable feature is the figuring in successive plates of all or most of the Chinese representatives of one genus, as for example, in *Carpinus*, *Tilia* and *Deutzia* In the first two fascicles the plates are spoilt, to a large extent, by being too heavily inked, but in fascicles 3 5 they are excellently reproduced from drawings (by C R Feng) which are both artistic and botanically accurate The publication forms a valuable work of reference for students of the flora of China, and it is to be hoped that it will be possible for production to continue, despite the unhappy conditions now prevailing in that country

Arctic Eskimo

a Record of Fifty Years Experience and Observation among the Eskimo By C E Whittaker Pp 260+16 plates (London Seeley, Service and Co, Ltd n d) 16s net

IN his fifty years of experience of the Eskimo Mr Whittaker has seen many changes In that period much of their traditional mode of life has passed away while in other respects although superficially there has been little modification conditions have altered fundamentally To mention one instance only though one that is most important for the future of the race the scarcity of game has adversely affected hunting and trapping activities and had not the Canadian Government intervened, the situation would have been parlous indeed

It was however the whaling industry that played the most serious part in breaking down Eskimo culture introducing the commodities, foods and especially drinks and the diseases of civilization When the whaling industry died out some thirty years ago the condition of the Eskimo began to improve and thanks to missions and hospitals as well as in a lesser degree to schools, progress has been continuous

In this volume the author is concerned with the traditional culture of the people rather than their present condition, although he glances at this incidentally His most permanent and valuable contribution to understanding of the Eskimo and the character of their culture lies in his personal observation and contact with individuals of which his memories provide a store His appreciation of their character with all its good qualities as well as its weaknesses is successfully conveyed to the reader

The author deals chiefly with the inhabitants of the Mackenzie Delta and Herschel Island, and the Copper Eskimo of Coronation Gulf who had not been visited by the white man before 1914 but his account of these peoples is made the basis of an account of the Western Eskimo in general

Grass Drying

By S W Cheveley Pp 127+9 plates (London Ivor Nicholson and Watson, Ltd, 1937) 6s net

THIS book fulfils a need in that it deals shortly but concisely with the whole subject of grass drying, tracing its development from the initial experiments at Cambridge to the product now turned out by the modern grass dryer The general principles of grass drying are well set out and some general idea of costs can be ascertained from the figures given It is unfortunate that all figures are taken for one make of dryer only, and that no figures are given for plants suitable for the farmer whose intention primarily is to supply his own requirements

The two chapters dealing with the management of the grass before and after cutting, and the general organization of the work, are well set out

The feeding value of dried grass is given, as are suggested methods of feeding the material to different classes of stock No results are quoted from actual feeding trials though many trials have been carried out Reliable information of this nature, from properly designed and managed trials is, however, still needed especially on the comparative value of spring and autumn dried grass Methods of feeding and amounts to be fed will probably need revising when experimental results relating to these subjects are available

No book dealing with a subject yet in its infancy can be expected to keep abreast of conditions for more than a short time Even now dryers other than those specified are being marketed, but no one contemplating the outlay on a drying plant can fail to benefit from reading this book J R M

The Production of Field Crops

a Textbook of Agronomy By Prof T B Hutcheson T K Wolfe and Prof M S Kipps (McGraw Hill Publications in the Agricultural and Botanical Sciences) Second edition Pp xvii + 445 (New York and London McGraw Hill Book Co Inc 1936) 21s

THIS is essentially a book written to meet the requirements of an American course of agriculture and it deals only with American crops and conditions, it makes no claim to be of direct use to students or teachers in Great Britain The terminology will be strange to English readers and many of the crop varieties mentioned are rarely heard of here

Some of the sections however are of interest to English readers One gives brief results of trials on the placement of fertilizers in relation to seed though with the information available from American sources, much more might have been made of this subject Another relates to the necessity of small quantities of the rarer elements for plant growth but the practical application of this knowledge is not discussed No mention is made of the use of mercurial seed dressings against bunt and smuts in cereals the formaldehyde and copper carbonate treatments being recommended J R M

The Naturalist's Calendar ("With Camera and Note book"), 1939

Edited by Phyllis Barclay Smith and Rudolf Zimmermann Pp 60 (London M C Forrester 1939) 3s 6d net

THIS handsome calendar should be welcomed by all lovers of natural history since it forms an attractive vehicle for some excellent Nature photographs which not only portray the beauties of plants and animals but are also an adequate and ready means of identification Each page on the calendar represents one week, but the letterpress is purely supplementary to the pictures The photographs are of mammals, birds, insects and plants found in Great Britain and have been chosen from among the best works of well known naturalists

The calendar would adorn the wall of a naturalist's study or a biological lecture room or laboratory It would make a very acceptable gift to anyone interested in the natural history of any group of plants or animals

The Physiology of the Plant Cell*

By Prof W. Stiles, F R S

IN spite of its great importance for the life of man the physiology of plants is a subject of comparatively recent development In its earlier phase during the eighteenth and first half of the nineteenth centuries it was very largely a study of plant nutrition from which emerged certain definite information regarding the functions of various plant organs and tissues It is only more recently that the study of the activities common to all living cells has come to the forefront of physiological inquiry These activities can conveniently be considered as of two kinds In the first place all cells respire in the sense that so long as they are alive actions proceed in them which involve the release of energy from certain substances With very few exceptions these actions take the form of a breakdown of carbohydrate or fat by oxidation to carbon dioxide and water The second kind of activity exhibited by all cells is to be found in their capacity for absorbing and excreting water and dissolved substances

It is usually accepted as a fact that every living cell respires and if this is so then we must conclude that respiration is something most inextricably connected with life The general view held regarding the function of respiration put in as precise terms as possible is that it provides energy for certain plant movements and for the building up of substances of higher energy content than the products of photosynthesis which serve as the substrate While perhaps all plant movements do not obtain the necessary energy for their occurrence from respiratory activity no doubt some do and there is every reason for believing that the energy required for the production of various constituents of the plant arises from the same process But having agreed to this can we really be satisfied that we have obtained a complete explanation of the function of respiration ? In the case of germinating seeds growing organs the formation of flowers and fruit this view seems completely adequate but we must remember that storage organs such as potato tubers and carrot roots respire at a by no means negligible rate and that the same is true of senescent organs such as mature fruit Indeed such tissues notably those of the apple have provided some of the most interesting data of plant respiration With what movement or with what synthesis of materials is respiration of the cells of the mature apple concerned ?

Such considerations lead one to wonder whether respiration is not concerned in some much more subtle way with the maintenance of life It looks as if the mere maintenance of the protoplasm in a living condition depends on the continuous occurrence of those processes which manifest themselves in the oxidation of organic material to carbon dioxide and water by means of absorbed oxygen The only exception to this rule is found in certain so called resting organs such as seeds in which the amount of water present is very low and in which presumably the protoplasm is in some very different state from that of active cells

If we cannot answer this question we can at any rate attempt an examination of the functions of respiration of which we feel more certain The most universal of these is the provision of energy for the building up of materials of higher energy content The chief problem which awaits solution here is the mechanism by which the energy released in the oxidation of the substrate is transferred to the actions bringing about the synthesis of proteins and other complex plant constituents A consideration of the relationship between aerobic respiration of apples in air and oxygen and anaerobic respiration in nitrogen led F F Blackman to the view that along with the breakdown of carbohydrate there is in air a process of oxidative anabolism in which some of the intermediate products of the breakdown of carbohydrate are built back into the system Evidence for oxidative anabolism in storage tissues such as potato tuber and carrot root has also been obtained in my laboratory by W Leach J K Choudhury and J K Scott while the investigations of Bennet Clark on the organic acid metabolism of succulents and other plants has led him to the conclusion that not only does oxidative anabolism occur in these plants but also that organic acids may quite generally play an important part in this phenomenon

While then data are accumulating which indicate the linkage of anabolic processes with those of the breakdown of sugar it is important to note that there is no evidence of the formation of products other than carbohydrates Is it not possible however that syntheses of more complex substances are indeed involved and that we have here a dim glimpse of the mechanism for the production of these substances and that along with the formation of sugar or some intermediate there may also be the formation of protein or other complex substances that indeed we have here the mechanism by which the carbohydrate is brought into a suitable form for combination with nitrogenous and other compounds? However this may be before we can hope to present a picture of the relation between respiration and vital syntheses we need not only many more data regarding respiration rates under both aerobic and anaerobic conditions but also a detailed biochemical analysis of the carbohydrate and various nitrogenous materials present in a wide variety of tissues So expressed this may sound a simple enough matter but actually as anyone who has attempted to tackle such problems knows it is one that abounds in difficulties

---

* Based on the presidential address read before Section K (Botany) of the British Association at Cambridge on August 18

While it has generally been assumed that respiration is linked in some unknown way with the synthesis of proteins and other substances its connexion with those other processes the absorption and excretion of materials which are characteristic of cells has only come to be appreciated more recently The absorption and excretion of water and dissolved substances was generally more or less tacitly assumed to be determined by the physical laws of osmosis and diffusion Water was supposed to diffuse into or out of the vacuole according to the difference between the osmotic pressure of the cell sap and the sum of the osmotic pressure of the external solution and the inwardly directed pressure of the stretched and elastic cell wall Dissolved substances were supposed to enter the vacuole according to the laws of diffusion expounded by Graham and Fick more than eighty years ago

Although Collander s work on the absorption of a number of non electrolytes indicates that this assumption may in the case of such substances be quite justified it has been known now for thirty years that the entry of electrolytes into cells cannot be explained as the simple diffusion of a substance through a membrane from a region of higher concentration to one of lower concentration During the years 1909 19 two facts militating against this simple view became established In the first place it was shown that the two ions of a salt could be absorbed by plant tissue at different rates while in the second place it was shown that absorption of a salt or its ions takes place towards a condition of equilibrium which is not that of equality of concentration attained inside and outside the cell but which depends on the concentration of the salt With dilute solutions the concentration attained inside the cell may be many times that of the solution outside while in concentrated solutions the reverse is the case and the concentration of the salt inside even after forty eight hours immersion of the tissue in the solution may be very much less than that outside Thus while more salt is actually absorbed from a stronger solution than from a weaker one the absorption relative to the concentration is less both as regards rate and total amount, from a stronger than from a weaker solution

Various possible mechanisms have been suggested to explain this relation between concentration and absorption When this problem was first investigated by F Kidd and myself we found that the relationship between concentration of salt and absorption was much the same as it would have been if the salt were adsorbed by an adsorbent within the cell It is easy to suggest that a first stage in the absorption of salts by plant cells is the adsorption of the ions of the salt by some constituent or constituents of the protoplasm While I have pointed out the similarity of the absorption of salts by plant cells with an adsorption phenomenon I have more than once stressed the point that this similarity is in itself not sufficient to justify the advocacy of an adsorption theory of salt absorption Yet it must be admitted that later work by more exact methods has only served to confirm the approximate similarity of the relationship between salt absorption and adsorption Reference in this connexion may be made to the work of Laine on the absorption of manganese and thallium by roots of *Phaseolus multiflorus* as well as to observations of my own on the absorption of sodium chloride by carrot root

Of course if the similarity between the relationship of salt absorption to concentration and th adsorption equation is more than a coincidence adsorption can only be the first stage in this absorption at any rate by actively growing tissues in which the absorbed ions must be transferred elsewhere Again one would expect the adsorbing material to be present in the protoplasm whereas a number of more recent observations by various investigators indicate that there is actually an increase in concentration of the absorbed ion in the vacuole The adsorption would then have to be followed by elution of the salt at the surface of the vacuole In this connexion it is interesting to note that S C Brooks has obtained some evidence that *Valonia* immersed in sea water containing rubidium chloride accumulates rubidium in the protoplasm for two days after which this cation passes from the protoplasm to both vacuole and external solution The same worker has also found that when cells of *Nitella* are placed in

0·01 *M* solutions of radioactive potassium chloride there is an accumulation of potassium in the protoplasm after six hours before any appreciable amount of potassium appears in the vacuole Previously M M Brooks had found that when *Valonia* is immersed in a solution of methylene blue, the cell wall and protoplasm become deeply stained by the dye before any appreciable coloration of the vacuole is observable

Another mechanism which has been suggested as possibly operative in the absorption of salts is one of interchange of ions within and without the cell under conditions which give rise to the ionic distribution between the cell interior and exterior characteristic of what is called Donnan equilibrium and in this connexion it must be emphasized that just as adsorption must take place if the cell contains adsorbents of ions capable of reaching the adsorbent so if the cell system involves the conditions giving rise to Donnan equilibrium it is inevitable that the movement of ions demanded by these conditions must result

The possibility that respiration has a direct effect in bringing about the absorption of ions has been pointed out by several workers notably by Briggs and S C Brooks The production of carbon dioxide in the cell leads to the appearance of carbonic acid and hence of its ions hydrogen and bicarbonate (H and HCO_3) The interchange of ions required by the Donnan equilibrium will lead to the diffusion out of hydrogen ions which are replaced by cations from the external medium while bicarbonate ions will be exchanged for anions from the external medium As the tissue continually respires the production of hydrogen ions continues to replace those which diffuse into the external solution and so the absorption of ions continues as part of an interchange between tissue and external medium

Against the view of a direct effect of respiration on salt intake by ionic exchange it has been urged by Hoagland and Steward that accumulation of ions is negligible or slight when tissue is deprived of oxygen although there may be a considerable anaerobic production of carbon dioxide But as regards this objection it must be noted that under conditions of anaerobiosis the rate of carbon dioxide production usually falls rapidly with time so that it is doubtful whether a considerable production of carbon dioxide anaerobically generally continues for any length of time The question is obviously one requiring further experimental investigation

That the absorption of salts by tissues is related to a supply of oxygen and probably in some way to respiration there can however be no doubt For more than thirty years it has been known that the growth of plants in water culture is often accelerated by aerating the solutions while more direct evidence of the effect of oxygen on the salt relations of cells has been obtained in work with storage tissues In 1927 I pointed out the importance of maintaining the supply of oxygen to such tissues for the maintenance of their vitality and that in the absence of an adequate oxygen supply exosmosis of electrolytes took place leading to the speedy death of the tissues whereas with maintenance of a supply of oxygen absorption of electrolytes continued in the case of beetroot for example for periods of about three weeks Towards the end of this time a condition of equilibrium was reached or approached in which the content of electrolytes in the external liquid was very low During this period conditions leading to lower oxygen and higher carbon dioxide concentration led to increase in the electrolyte content of the liquid while addition of fresh oxygen led to a decrease

In similar experiments carried out by Briggs and Petrie in 1931 in which a continuous stream of air was passed through the liquid these workers examined the course of respiration along with the changes in electrolyte content of the external solution and established the fact that there is a general parallelism between the rate of respiration of the tissue and the electrolyte concentration of the external liquid If the stream of air was replaced by nitrogen the respiration rate increased and so did the concentration of electrolytes in the solution while replacement of the nitrogen by air brought back the original distribution of electrolytes between tissue and external liquid Steward and collaborators have shown that reduction of the oxygen supply to storage tissue of potato carrot and artichoke below a certain value limits the accumulation of both the ions of potassium bromide by the tissues while Hoagland and Broyer have obtained a similar result with barley root systems

In attempting to explain this effect of oxygen one must bear in mind that the relationship between respiration and salt accumulation may not be a direct one The maintenance of an adequate supply of oxygen is necessary to maintain the vitality of the tissue possibly on account of the deleterious effects of the products of anaerobic respiration Thus the fact that accumulation depends on oxygen supply may be regarded as an expression of the fact that under conditions of partial or complete anaerobiosis the functioning of all or many vital processes dependent on the protoplasm is adversely affected and along with them that of salt accumulation From this point of view the effect of conditions leading to poor oxygen supply may be related not only to oxygen concentration but also to accumulation of carbon dioxide and other products of anaerobic respiration

From a consideration of all the data it seems to me that the following conclusion can be drawn regarding the relationship of respiration to the absorption of salts by plant cells namely that accumulation of salt depends on the vitality of the cells and that the maintenance of this vitality depends as has been long recognized on the presence of oxygen either because aerobic respiration or some other process requiring oxygen is essential for this maintenance of vitality or because in the absence of oxygen the accumulation of carbon dioxide and other products of anaerobic respiration adversely affects the functioning of the protoplasm This dependence of absorption of salts on the vitality or healthiness of the tissue was clearly shown by my experiments of 1927 and by the later ones of Steward in which stress was laid on the effect of aeration of the tissues I think Hoagland s observations on the effect of light on absorption of potassium bromide by *Nitella* fall into line with these It was found that absorption of bromide only took place if the cells were exposed to light or if they had previously been exposed to adequate illumination If for some time previously they had been growing in weak light no accumulation of ions took place *Nitella* kept for some time in low light is probably somewhat unhealthy just as is tissue that is deprived of an adequate supply of oxygen In other words most of the work published on the relationship between respiration and salt accumulation does no more than show that this accumulation is a vital process depending on the normal functioning of the protoplasm Any general relationship between respiration and salt accumulation as regards the linkage of reactions involved or the transfer of the energy required for the entry of a salt against its own diffusion gradient may thus be very indirect

Thirty years ago when the importance of the principles of chemical dynamics in life processes was coming to be fully realized it looked as if the solution of many of the problems of plant physiology in terms of physical chemistry was fairly imminent But with the application of these principles to our investigations into living processes we find that in every one of them the protoplasm introduces a factor which renders these processes not readily explicable in this way Clearly we must seek an explanation in the apparent divergence of vital processes from physical or chemical laws in the constitution of the protoplasmic system and hence a fuller analysis of this system now appears to be a requisite for further advance in our understanding of physiological processes in general There is at present no reason to suppose that with further advance in knowledge of the protoplasmic system we shall not ultimately be able to explain physiological processes in physico chemical terms and I would re affirm what F F Blackman emphasized in his presidential address to Section K thirty years ago namely the inevitableness of physical chemical principles in the cell

It is scarcely necessary to emphasize how the principles of general cell physiology must be of fundamental importance in plant metabolism for inasmuch as this depends on the activity of specialized cells and tissues these wherever they are alive must also exhibit the normal features characteristic of protoplasmic activity But in spheres of botanical science outside the range of pure physiology the general physiology of the cell is just as important This applies in particular to ecology This study in so far as its aim is the determination of the relationship of plants to their environment is indeed nothing else than physiology a fact which was clearly recognized by Clements more than thirty years ago

Of the two groups of factors which determine the distribution of vegetation the climatic and edaphic the mode of action of the latter in particular can only be studied with any hope of success by those with an adequately deep knowledge and appreciation of cell physiology It does not need a knowledge of physiology it is true to determine plant distribution but such knowledge is essential for what Tansley in a paper read to Section K thirty four years ago called the higher branch of ecology i e the detailed investigation of the functional relations of plant associations to their surroundings However desirable and necessary the collation of knowledge of plant distribution may be I am certain that the solution of the fundamental problems of ecology will only be achieved by the use of physiological methods and particularly by the application of our knowledge of the general physiology of the cell For edaphic factors must act through the root and by the absorption of materials from the soil or the exchange of material between the soil and root

Certain aspects of mycology have much in common with physiology indeed that part of mycology which concerns pathogenic organisms is inevitably closely linked with problems of the relation of host and parasite problems which are in their very essence physiological Years ago it was questioned whether the physiology of the plant physiologists was not half pathology Certainly the reverse question can be answered with more assurance, pathology is at least partly physiology and therefore the principles of general cell physiology must here also be of immense importance, and an intimate acquaintance with these principles should be an important part of the equipment of the plant pathologist

Perhaps no branch of botany has made such spectacular advances in recent years as that of cyto genetics At least it has produced a nomenclature which rivals or excels the early efforts of the descriptive ecologists and just as descriptive ecology can do little more than correlate certain types of vegetation with certain environments so cytology can do little more than correlate visible structures in the cell with genetical behaviour I cannot help thinking that a real insight into these problems also will only come with the interpretation of cytological observations in physiological terms and that the greatest advance in the study of cytology will come with the linking up of the knowledge of the cell acquired by these two lines of investigation the cytological and physiological It is surely a rather remarkable fact -one indicating how far away we are at present from the achievement of this end that the physiologist tends to think of the *cytoplasm* as the essential factor in determining vital activities while the cytologist concerns himself almost exclusively with the nucleus Neither the physiologist nor the cytologist appears at present to have anything but the vaguest ideas of the relationship between the two a relationship which however we may feel sure is most intimate and fundamental to life

We all know but it cannot be too strongly emphasized that botany is the pure science of a great part of the most important industry of the world agriculture and that this like every other industry can only be carried on wisely if its practice is based on scientific principles Almost all branches of botany are important for agriculture but mycology, genetics and physiology are particularly so and certainly physiology is not the least of these Absorption of water and nutrients from the soil assimilation of carbon water relations of the plant vegetative development flowering and fruiting are all problems of agriculture and forestry which are essentially physiological

But besides these more obvious economic applications there are numerous industries in which the principles of general cell physiology are no less fundamental There are all those industries ever increasing in number and importance which are based on some particular plant product such as cotton linen jute rubber tea sugar and tobacco to mention only a few of the more important Apart from the growing of the plants themselves which like any other form of agricultural practice should be based on sound physiological principles a knowledge of these principles may be equally important in the subsequent treatment of the plant material In particular a knowledge of cell organization, the action of enzymes contained in the cell its behaviour towards various reagents all aspects of general physiology is essential Finally the great food storage industry depends greatly on the application of knowledge of cell physiology As an example of this I may refer to pioneer work on the scientific principles of cold storage by Jorgensen and myself carried out some twenty years ago From a consideration of what was then known of the constitution of the cell we concluded that the satisfactory preservation of certain tissues in the frozen condition depended on rapidly freezing the tissues a method which was afterwards put into practice in certain branches of the food storage industry This is of course only one instance of the bearing of general cell physiology on the subject of food preservation The effect of the conditions of storage on enzymes and other cell constituents and on the vitality of different kinds of cells tissues and organisms are among the problems which a knowledge of the facts and methods of general cell physiology will help to solve

With the ever increasing mass of knowledge in the various branches of botany an increase which is especially noticeable to day in those aspects of our subject which are undergoing rapid development namely physiology mycology and genetics with cytology it is impossible for anyone to be an active worker in more than a relatively very small field of botanical endeavour We sometimes meet with reference to a mysterious gentleman called the general botanist who is expert in general botany as someone distinct from the morphologist physiologist mycologist or other worker in a defined field But in these days when to make any contribution to knowledge necessitates specialization there can indeed be no such person as the expert in general botany for there is indeed no such subject But in whatever part of our subject our own special interests may lie we can still appreciate the efforts and aims of workers in other fields and realize the bearing of work in these fields on our own problems and in this sense we are all general botanists that is just botanists

For if general botany as something distinct from botany is a myth there is no doubt that the various branches of our subject are related in the whole I have here tried to indicate not only the scope and present position of our knowledge of the general physiology of the cell but also where this particular part of the science of plants comes into contact with other branches of botany and how the application of a knowledge of the facts, principles and methods of cell physiology may be expected to lead to an increase in knowledge not only of the physiology of the plant but also of other aspects of botanical science and of its industrial applications

The Perkin Tradition

DURING the Easter holidays of 1856 a young man of eighteen years of age was experimenting at home in Shadwell in chemistry He followed up the coloured product of the reaction instead of chasing after a more orthodox crystalline substance and strangest of all had the curiosity to try to dye silk with it A mauve skein resulted and the aniline dye industry was born !

Perkin's father was a builder and looking back he must have been a man of remarkable character Not only did the son experiment at a very youthful age as in those halcyon days was customary but also he seems to have been encouraged to try his hand in many directions until finally between twelve and thirteen years of age he came to chemistry and to Thomas Hall at the City of London School He next sought to go to the Royal College of Science this was going a little too fast for the father for chemistry was scarcely a profession in those days but with Hall's assistance the young Perkin had his way and was allowed to study under Hofmann

Mauve was discovered at home and perhaps its properties received more discussion in the family circle than they would have done in a laboratory In any event Perkin there and then started to make his dye while his father risked most of the capital which he had accumulated by a life of great industry to build and start the works There can be no more outstanding example of confidence in a young son and paternal enterprise Such a thing is utterly impossible to day in any country the name of George Fowler Perkin should be highly honoured by posterity

W H Perkin was fortunate in another way there was no school certificate or matriculation examination to dominate his education What is the use of trying to turn out all the boys to day in a common mould when we are really every one of us different the examination system destroys any chance of incipient genius and is the negation of education scientific or otherwise Perkin would have probably passed his examination but the preparation for it would have left him no time to express his individuality Surely this is the chief lesson to be drawn at the time of celebrating the centenary of his birth

The call to invent to prosecute research is strongly hereditary though perhaps latent in the founder of the family Sir William passed it on to all three sons particularly to W H junior and it is a loss to science that there has been no third generation

The story of the Perkin adventure has been often told in the greatest detail and from many aspects particularly in relation to the rise and fall of the industry in England its transference to Germany and its more recent resurrection here The jubilee of the discovery in 1856 gave the chemical world an opportunity to honour Perkin The centenary of his birth was celebrated on November 24 last by a memorial lecture given by Dr Herbert Levinstein in the hall of the Leathersellers Company and arranged by the Society of Chemical Industry and the Chemical Society The selection of speaker was a happy one Levinstein's father maintained a dye industry in Great Britain during the darkest days of its difficulties and father and son supplied a nucleus on which it was possible to condense other efforts when the upswing began No more comprehensive illuminating balanced and graceful address has ever been forthcoming on this subject the simplicity of its language makes it of wide appeal The societies must give it full publicity it should at least be read by every member of Parliament to make them realize the significance of chemical effort for the benefit of man perhaps educationists may be led to ponder also how they are going to preserve further Perkins for us and not destroy them in their teens

Perkin's ability as an applied chemist was remarkable At an age when the young men of to day are still playing games he made discoveries in dyeing practice which Levinstein rightly regards as a more considerable achievement than the laboratory discovery of mauve The new mauve dyed silk direct but very irregularly he found it dyed level shades if applied to silk in a soap bath a novel method which has never since gone out of practice Mauve would not dye cotton far and away the most important textile fibre without a mordant Perkin in 1857 when he was nineteen years of age discovered the tannin method since found of general application to basic colours He did much also to make calico printing with the new dyes possible

Perkin only remained seventeen years in industry selling out when he was thirty five years old he had amassed what was for him in those days a competence In so doing he displayed great shrewdness as after events disclosed in leaving the industry when it was in a very flourishing condition In later life he showed relatively little interest in the industry and some have blamed him for cutting himself so soon adrift from his own offspring. The business side of the factory was looked after by his brother Thomas.

The rest of Perkin's life was devoted to pure research. He has himself told us that he determined not to let the manufacturing career check his scientific life. It is not at first glance easy to understand why he could be happy in the study of such subjects as magnetic rotation. To quote Levinstein: 'this physicochemical work is of great difficulty but I should have thought of quite exceptional dullness for a man who had created vast industries'.

I saw a good deal of Perkin in this last phase of his life, when it was hard to believe he had been so active as a young man. Most of us, like my own father, carry on such activity until incapacitated: the contrast between Perkin and Duisberg of the I.G. at the same advanced age was a remarkable one. Perkin followed a rigid and austere vegetarian diet and it may be that it contributed in some way yet to be discovered to this change of outlook. But he was by disposition a man of most retiring nature.

It is the duty of the chemical societies to keep the memory of Perkin from fading from the public mind. His achievements were startling and will be remembered when the names of the statesmen of to day are long forgotten. There is a great tradition to be kept alive.

> "A crown of fame! Fulfilment of thy work
> well done
> And knowledge of a people's gratefulness."

E. F. A.

Obituary Notices

Sir Henry Fowler, K.B.E.

HENRY FOWLER, who died on October 16, at the age of sixty eight years, was born at Evesham on July 29, 1870. His technical education started at the Mason Science College, Birmingham, and was continued at the Railway Mechanic's Institute at Horwich during his apprenticeship in the locomotive works of the Lancashire and Yorkshire Railway. Whilst at Horwich, Fowler gained the first Whitworth Exhibition to be awarded to a student of the Institute. After service under Sir John Aspinall, with whom he was associated in a series of classic experiments on train resistance, Fowler left Horwich to become gas engineer of the Midland Railway at Derby, where, a few years later, he became works manager of the locomotive works, under R. M. Deeley, whom he eventually succeeded as chief mechanical engineer in 1909. During the Great War, Fowler successively held the positions of director of production, Ministry of Munitions; superintendent of the Royal Aircraft Factory, Farnborough; and assistant director general of aircraft production, Ministry of Munitions; for these services he was created C.B.E. in 1917 and K.B.E. in 1918.

Consequent upon the amalgamation of the railways of Great Britain in 1923, Fowler was appointed deputy chief mechanical engineer, and two years later he succeeded George Hughes as chief mechanical engineer of the L.M.S. Railway. From January 1931 until December 1932 he was assistant to the vice president, and during these two years he was able to devote the whole of his energies to research and development, unhampered by the large volume of administrative work inseparable from his earlier appointments.

Although responsible for the design of several new locomotive types including the well known "Royal Scot" class, perhaps Fowler's greatest flair was for works' organization. He also realized the vast economies that could be attained by the standardization of locomotive parts, and he was an early and successful exponent of the policy of reducing the number of different types of locomotive to a minimum.

Fowler was always an enthusiastic participator in the activities of the various institutions to which he belonged, and he ultimately became president of the Institution of Mechanical Engineers, the Institute of Locomotive Engineers, the Institution of Automobile Engineers and the Institute of Metals. His keenness in furthering the interests of such bodies was coupled with a deep sense of the importance of technical education and scientific research to industry. He did a great deal to facilitate the higher technical education of the many apprentices and pupils who passed through the Derby works during his time, and he was always ready to give up his leisure to address educational and scientific bodies, and to give freely of his accumulated experience.

Of Fowler's scientific work it is difficult to speak fairly. He had no time for carrying out personally many of the investigations which he, often before his colleagues, saw were necessary; but he had an extraordinary gift of encouraging others, both within and without the railway service, to follow the lines he had indicated, and he was always most generous in providing facilities for trying out other people's ideas. In all this work he maintained an almost boyish enthusiasm, and was never happier than when he was able to spare the time to discuss the progress of some particular research with those who were actually conducting it. He was also skilful in securing the interest of eminent scientific workers in his locomotive and metallurgical problems, and he undoubtedly established for the former Midland Railway a reputation for sympathy towards scientific methods.

Fowler would probably have agreed that crank axles and boilers were the subjects that fascinated him most and his investigation into the life of the former was an almost classic example of the statistical use of a vast mass of metallurgical evidence The many problems connected with the locomotive boiler also held a great appeal and he could never resist the temptation to inspect personally any boiler that had developed some peculiar defect in service Even on his many visits abroad he invariably took his boiler suit with him and excited the admiration of his hosts (and of the writer) by his skill in negotiating the not always easy entrance to the barrel or firebox of a locomotive Therein he showed how thoroughly he understood the value of personal observation which is so essential in engineering and metallurgical research F M H

Prof P A Murphy

PAUL ALOYSIUS MURPHY whose death at the age of fifty one years occurred on September 27, was born in Co Kilkenny After courses at the Albert Agricultural College, Glasnevin, and the Royal College of Science, Dublin, extending over five years, he was appointed to a temporary post under the Irish Department of Agriculture and started research in plant pathology Later, with a Development Commission scholarship, he proceeded to the Imperial College of Science and Technology, London and to the K Biologische Reichsanstalt, in Berlin Dahlem Leaving Germany in 1914, and being rejected on medical grounds for active service, he completed his scholarship period at Cornell University He was then appointed plant pathologist in Prince Edward Island by the Canadian Government He returned to Ireland in 1921 to similar work in the Department of Agriculture there and six years later was appointed to the newly created chair of plant pathology in University College, Dublin, which he held until his death

Murphy's scientific work was very largely concerned with research on potato diseases After having helped to show the bacterial nature of the so called black leg' disease and to prove that the blight fungus (*Phytophthora infestans*) was capable of producing sexual spores—a much vexed problem up to that time—he worked out the cytology of the peculiar mode of sexual reproduction in the newly discovered allied species *P erythroseptica* Later, he considerably extended his work on the bionomics of *P infestans*, but devoted much attention to virus diseases such as leaf roll, mosaic, crinkle and streak His contributions to a scientific knowledge of these obscure diseases were particularly extensive and important, and received world wide recognition As a result of his investigations and those of a few other pioneers, the production of healthy stocks of potatoes has been placed on a sound scientific basis and important advantages to practical agriculture have already accrued To mark his eminent work in the sphere of potato husbandry, Murphy was awarded the John Snell Memorial Medal by the National Institute of Agricultural Botany in 1927

At his old college at Glasnevin (now incorporated with University College, Dublin) Murphy developed a vigorous school of plant pathology, and the sound work of himself and his colleagues there not only on virus diseases but also on others such as onion mildew swede dry rot, sugar beet crown rot and American gooseberry mildew, is a testimony to its wide scope and to Murphy's inspiring and untiring devotion to research in plant pathology

Murphy graduated at the University of Dublin (Trinity College) in his student days and was awarded the Sc D degree in 1922 He was a member of the Royal Dublin Society and a valued member of its Science Committee For his published researches, the Society awarded him the Boyle Medal in 1933, and at the time of his death these were approaching fifty in number He was also a member of the Royal Irish Academy of the Phytopathological Society of America and of the Agricultural Research Council's Committee on Virus Diseases of Plants

Murphy's loss will be deplored in wide circles, for he was always ready to help other workers Many of them, both at home and abroad, will gratefully remember his generosity in the distribution of strictly dependable material—the product of his own careful and protracted work—which greatly facilitated their own investigations He leaves a widow and two sons, for whom the deepest sympathy is felt

G H P

MR ROSSE BUTTERFIELD, of High Cote, Riddlesden, Yorkshire curator of the Keighley (Yorkshire) Corporation Museum who died recently at the age of sixty four years was a well known naturalist of the West Riding He came of a Wilsden family of naturalists and his father was a well known authority, another member of the family was the late Mr Ruskin Butterfield, formerly curator of the Hastings Museum Mr Rosse Butterfield did much valuable work in connexion with organizations of naturalists, and he was himself known for his work in entomology He had been the curator at Keighley Museum since 1910 and was due to retire next year Under his guidance the development of the Museum collections and of education in natural history has made rapid strides He was a member of the executive of the Yorkshire Naturalists' Union and was secretary of the Keighley Naturalist Society He was a member of the committee of the Bradford Natural History and Microscopical Society and was recorder for Hymenoptera Formerly, Mr Butterfield was curator of the Bronte Museum at Haworth

---

WE regret to announce the following deaths

Sir James Barr, C B E , consulting physician to the Liverpool Royal Infirmary, known for his work on the diseases of the blood vascular system, on November 16, aged eighty nine years

Prof J W Bews, principal of Natal University College and professor of botany in the College, aged fifty three years

Prof William McDougall, F R S , professor of psychology in Duke University, North Carolina, aged sixty-seven years

News and Views

Dr. G S. Whitby

As announced in NATURE of November 5, p 828, Dr George Stafford Whitby, for the past nine years director of the Division of Chemistry, National Research Council of Canada, has been appointed director of the Chemical Research Laboratory of the Department of Scientific and Industrial Research, London In Canada, Dr Whitby has organized and directed chemical research in many lines, not a few leading to industrial applications and developments At the age of sixteen years, he entered the Imperial College of Science and Technology, London, where he worked under Sir William Tilden Following graduation, he spent four years on the staff of the Imperial College in teaching and research under Sir Edward Thorpe He then spent seven years in the East Indies as chief chemist to a group of British French and Belgian rubber companies His work there had a marked influence on the development of the rubber industry, and established him as one of the leading rubber chemists of the world He was appointed assistant professor of organic chemistry in McGill University in 1918, and eventually associate professor and full professor Dr Whitby has published seventy seven scientific papers chiefly in the realms of organic and colloid chemistry In 1929 he was selected to take charge of the Division of Chemistry of the National Research Laboratories, Canada Many of the research programmes initiated by him have yielded results of commercial value, notable examples being the development of refractories, improvement of testing methods and means for the utilization of asbestos, the application of research to the problems of laundering, the development of processes for the utilization of waste natural gas, studies in wool, leather, rubber and other materials of commerce

Prof. J. Plotnikow

PROF J PLOTNIKOW, director of the Physico-Chemical Institute in the technical faculty of the University of Zagreb (Jugoslavia), will celebrate his sixtieth birthday on December 4 Prof Plotnikow is very well known for his numerous investigations in photochemistry and photography, and for various books, amongst which may be mentioned "Photochemische Versuchstechnik" (2nd edition, 1928, Akademische Verlagsgesellschaft, Leipzig), "Grundriss der Photochemie' (1923, W de Gruyter, Berlin); "Photochemie fur Mediziner" (1928, G Thieme, Leipzig); and "Lehrbuch der allgemeinen Photochemie" (2nd edition, 1936, W de Gruyter, Berlin) He was born at Tambow, Russia, was a student of physics and mathematics at the University of Moscow until 1901, and from 1901 until 1908 worked in Ostwald's Institute at Leipzig, in which he was appointed assistant in 1906 Returning to Moscow, he became professor in 1916, but lost his position, his property, and very nearly his life in the Russian revolution After a year as director of the scientific laboratory of the 'Agfa" Company (Berlin), he became in 1920 a professor at Zagreb For his discovery of 'infra red shadow photography' he received the 'Goldene Verdienstsmedaille of the Vienna Photographic Society

Prof A Sommerfeld

PROF ARNOLD SOMMERFELD professor of theoretical physics in the University of Munich, will celebrate his seventieth birthday on December 5 He is able to look back on a long and successful career in mathematical physics, both in research and in teaching. During the time of his tenure of the chair in Munich, where he succeeded Boltzmann in 1905, his modest institute became the centre for students of physical theory many of whom went there from abroad for a period under his inspired guidance Among his numerous pupils who now occupy high positions in the academic world, Debye, Pauli and Heisenberg may be mentioned

Social and International Relations of Science

THE British Association has now constituted a committee to work the Division for the Social and International Relations of Science which was established at the recent meeting of the Association in Cambridge The committee, under the chairmanship of Sir Richard Gregory, includes the president and general officers of the Association *ex officio*, Sir Daniel Hall, Sir Frederick Gowland Hopkins, Sir John Russell, and Lord Stamp as vice chairmen, and as other members Prof F C Bartlett, Prof J D Bernal, Prof P M S Blackett, Mr Ritchie Calder, Mr A M Carr Saunders, Prof S Chapman, Dr C H Desch, Prof A C G Egerton, Prof H J Fleure, Mr E W Gilbert, Prof N F Hall, Mr R F Harrod, Prof A V Hill, Sir Clement Hindley, Prof L Hogben, Dr L E C Hughes, Dr J S Huxley, Mr D Caradog Jones, Prof H Levy, Dr C S Myers, Mr Max Nicholson, Sir John Orr, Prof J C Philip, Prof J G Smith, Prof R G Stapledon, Prof F J M Stratton, Prof F E Weiss, Mr H G Wells, Mr J S Wilson, Dr S Zuckerman The main purposes of the Division are stated to be "the objective study of the effects of advances in science on communities, and reciprocally the effects of social conditions upon the progress of science, and the encouragement of the application of science to promote the well being of society"

THE committee is empowered to arrange meetings of the Division to co-ordinate work dealing with the social relations of science, both at home and abroad, to be prepared to act in a consultative capacity and to supply information to organizations, individuals and the public, to initiate and carry out inquiries and research, and to secure their publication. An executive sub-committee has prepared an extensive programme of work for the full committee, which at a meeting on November 28, appointed a number of other sub-committees to deal with specific matters. These include such topics as the economic requirements of nations, the influence of scientific and technical developments on the relative importance of different industries and on the total volume of employment, the question of supplementing existing national research organizations whether in normal circumstances or at time of emergency, and the co-ordination and subsequent public presentation of work on nutrition and agriculture. Contact has already been established with organizations at work on such subjects as a survey of research in Great Britain, the prospective effects of changes in the population structure on economics, society, and occupations, and the incidence of taxation on scientific research. It is hoped to co-operate with the International Council of Scientific Unions, which has already set up a Committee on Science and its Social Relations with the view of preparing a report of world-wide scope.

Jundhi Shapur

AT a meeting of the Section of the History of Medicine of the Royal Society of Medicine on November 2, Dr. Cyril Elgood gave an interesting account of Jundhi Shapur, which was famous as the site of a university in south-west Persia, probably founded about A.D. 340. The Arab invasion of Persia took place when Jundhi Shapur was at the height of its fame. The city surrendered in A.D. 636, but was left undisturbed, and the University remained the greatest centre of medical learning in the Islamic world until the foundation of the school of medicine in Bagdad. The system of medicine taught at Jundhi Shapur was predominantly Greek, but indigenous medicine, Indian medicine and possibly Chinese medicine were also studied there. The teachers of Hippocratic medicine were reinforced by the exodus of the Nestorian professors from Edessa in 489 and of the Neo-Platonists from Athens in 529. There was also a constant flow of individual Greek physicians to the Persian royal service. The importance of Jundhi Shapur lay in its being a store-house of Greek tradition when Rome was no longer the capital of the Empire and when Constantinople was more interested in theology than in science. It was the cradle of the great Arabian school of medicine and provided most of the translators who rescued Greek texts from oblivion, thus forming the source of the renaissance of medicine in Europe. Owing, however, to the constant transfer of physicians to Bagdad, the school of Jundhi Shapur declined, and by the twelfth century ceased to function.

Awards of the Mary Kingsley Medal

PRESENTATIONS of the Mary Kingsley Medal to five recipients were made on November 23 at a reception at the Liverpool School of Tropical Medicine by its chairman, Viscount Leverhulme. This medal, struck in commemoration of the late Miss Mary Kingsley, niece of Charles Kingsley, distinguished for her work in promoting the welfare of the natives of West Africa, is awarded in recognition of services in the cause of fighting and preventing disease in the tropics. After the chairman had welcomed the guests, Prof. Warrington Yorke introduced the recipients of the medals, briefly outlining the grounds for the awards. They were: Lady Danson, honorary recipient, widow of the late Sir Francis Danson, who was Chairman of the Liverpool School over a lengthy period, and was largely responsible for the establishment of the School's research laboratory at Freetown, West Africa, and herself undertaking the duties of chairman during her husband's absences; Dr. Marshall A. Barber, with a long and distinguished association with the International Health Division of the Rockefeller Foundation, and recognized for his researches on malaria and for his work on the hookworm, and inventor of the micromanipulator; Prof. Emile Brumpt, of the University of Paris, distinguished for his researches on tropical parasitology; Prof. W. Scott Patton, emeritus professor of entomology in the School, formerly in the Indian Medical Service and director of the King Institute, Madras, well known for his researches on kala azar and oriental sore; and finally Werner Schulemann, professor of pharmacology, University of Bonn, the discoverer of the anti-malarial drug plasmoquine, which gave a great impetus to chemotherapy.

Early Anatolian Civilizations

MISS WINIFRED LAMB'S account of her third season of excavation at Kusuru, south-west of Afyon Karahissar in Anatolia, which was given before the Society of Antiquaries of London on November 17, emphasized the importance of this little-explored region for knowledge of the cultural distributions of Asia Minor in the third millennium B.C. Miss Lamb was able to demonstrate that at this early period the distinction which has been drawn between the cultures of eastern and western Anatolia is by no means so clearly defined as has been thought. The culture of the community of Kusuru in the third millennium, she finds, had much in common with that of the western Anatolian group; and she would regard the two, not indeed as dissociated, but rather as independent developments of the culture of peoples of a common stock. A relatively advanced stage of civic development is indicated by the disposition of the houses on either side of a street. These architectural remains are well preserved, and in some instances still rise to a height of more than three metres. A period of disturbances and the partial destruction of the settlement at about 2000 B.C. was followed by the appearance of a new race. The town was rebuilt and its citadel enclosed by a double wall with a gateway on the west. On the evidence of the pottery, implements and cult objects it is possible to conclude that this new people was identical with that which formed the bulk of the population of the chief Hittite centres at Boghazkoi, Alishar and Alaga. This is the first occasion on which this culture has been found so far to the south-west. Its presence here may be expected to throw light on the difficult ethnological and historical problems of the second millennium B.C.

Prehistoric Pottery in Kent

THE results of further excavations in the Bean Valley, Kent, upon which Mr. J. P. T. Burchell made a report before the Society of Antiquaries of London on November 24, have failed to support the suggestion that the pottery discovered here in a previous investigation was of palæolithic age (see NATURE, 140, 800; 1937). The evidence upon which Mr. Burchell relied in making such a suggestion was in part the absence of a mesolithic culture in the lower beds of the series in which the pottery occurred, in part the presence in the deposits of shells of the extinct *Helicella striata*, not previously recognized later than the Upper Palæolithic. Mr. Burchell's further examination of the site leads him to agree with the dissentient opinion previously expressed that this pottery is to be assigned to the early bronze age. It has been shown by this season's excavation that *Helicella striata* outlived the last glacial phase and survived into the mesolithic period. What was thought to be collateral evidence from Springhead in the Ebbsfleet valley in the form of striated implements showing the effect of glacial action has now proved to be later in date than two mesolithic floors in the valley, and consequently some other explanation of their condition must be sought. The excavations in the Ebbsfleet valley in the course of this further investigation have been pursued in exceptionally favourable conditions owing to pumping operations. It was found possible to excavate the bed of the stream to a depth of ten feet, and remains of cooking pots, decorated within and without, of a type not previously found in Britain, with flint flakes and fragments of worked wood of late mesolithic dating, were found in a grey silt below ten feet of peat.

Electricity in Coal Mines

IN a paper read by Mr. R. Nelson to the Institution of Electrical Engineers on December 1, a retrospect is given of the use of electricity in coal mines during the last thirty years and also a forecast of what still remains to be done before the mines of Great Britain are fully electrified. In the year 1883, the first electric motor pump was used to pump water from a coal mine; it was only 1½ h.p., but there was then only very little mechanical power used for any purpose below ground. Twenty-five years ago the most disastrous explosion in the history of British mining, namely, that at Senghennydd Colliery, South Wales, had the effect of causing the miners to call for the removal of electricity from the pits. Happily, by the application of systematic stone dusting a means was found of preventing the spread of an explosion of gas or coal-dust, and thereafter the miners' opposition lessened at any rate in degree, but it has not yet disappeared. During the last ten years, the coal industry has been greatly assisted by mechanized mining and mechanical methods of coal sorting. These, with normal development in other directions, have resulted in a total of more than two million horse-power of motors installed in 1937, half of them being below ground. Accident statistics are touched upon. It is recorded that taken over ten years, 1927–1936 inclusive, electricity has been responsible for 224 out of 8 656 deaths, or 2½ per cent of the total loss of life in the pits. Electricity and compressed air are rival sources of power for the machine cutting of coal. In 1937 seventy per cent of the machine-cut coal was cut by electricity. It is satisfactory to learn that in some of the recently developed South Yorkshire and Nottinghamshire coalfields, their transmission mains are interconnected, a very desirable example of co-operative working. The wider provision of cheap and unlimited current by the grid, for example, would facilitate the use of electricity for all colliery purposes, and would improve the economics of the coal industry by materially assisting mechanical mining. The author concludes with an appeal to electrical engineers to capture the confidence of the miners.

British Museum (Natural History): Acquisitions

MRS. MARY V. WALKER has presented to the Department of Zoology a set of photographs which were taken by her husband, the late Dr. William D. Walker, depicting the early life-history of kangaroos. The photographs show the kangaroo in all its stages from the newly born young on to the adult and mature individual. The first of the series shows the newly born kangaroo having just made its way into the pouch and it is seen adhering to one of the nipples. At this stage the animal is very embryonic and bears but little resemblance to the massive creature into which it will grow, being scarcely more than an inch in length and looking more like a fragment of raw flesh than the young of any animal. A skin and seven skulls of a rare species of otter (*Paraonyx microdon*) have been presented by Mr. M. D. W. Jeffreys. Mr. J. E. Perkins, assistant keeper in the Department of Entomology, spent six months from April until September 1938 in Sweden partly in the study of the important Thomson Collection of Ichneumonidæ (Hymenopterous insects the larvæ of which are parasitic on the larvæ of other insects), and partly in collecting insects, chiefly Ichneumonidæ, from the localities in Sweden where most of Thomson's specimens were obtained. More than 40 000 specimens of Hymenoptera were collected, of which 12 000 were Ichneumonidæ. A large quantity of the material obtained was identified and compared with the Thomson Collection before leaving Sweden, and the specimens so dealt with were found to represent 540 different species of which 260 were not previously to be found in the British Museum (Natural History). The collections obtained by Mr. Perkins constitute an important addition to the Entomological Department, and for the large number of specimens acquired and for the work done upon them in Sweden the Museum is indebted not only to Mr Perkins but also to his wife, who accompanied and assisted him Recent acquisitions in the Geological Department include nearly 300 invertebrate fossils from the Tertiary of the West Indies collected and presented by Dr C T Trechmann

THE Department of Botany has received the first consignment (2 800 specimens) of Dr Carl Christensen's fern herbarium Dr Christensen is the chief authority on the taxonomy of ferns and is the author of Index Filicum It is estimated that the collection comprises more than 14 000 specimens with more than 800 types and 800 co types and in addition fragments of 900 types and co types, also more than 4 000 drawings, photographs and figures The herbarium is without doubt the most important collection of ferns in private hands and will add enormously to the value of the important fern section in the Department The original drawings (426) illustrating the late E D Heathcote's Flowers of the Engadine have been presented to the Department by his daughter, Mrs D Lee A further 600 specimens of flowering plants collected by Dr H Smith in Western China have been purchased These are well collected and preserved and contain several co types A collection of 984 lichens from northern Norway and from Baffin Land made by Dr N Polunin has been purchased Although these are rather fragmentary owing to the difficulties of transport, the collections are important because they have been examined by experts and are the token specimens for several distribution records

Wild-Life of North-West England

IN a lecture to the Blackburn Naturalists Field Club on November 26 Mr Eric Hardy mentioned that oyster catchers curlew woodcock redshank tawny owls and spotted woodpeckers are all increasing their nesting range in Lancashire and Cheshire, but the terns are becoming fewer at the well known Ainsdale sea bird sanctuary His subject of On My Rounds Notes From a Naturalist's Notebook described his field studies in Knowsley Park where great crested grebes, sandpipers, kingfishers and goldcrests are all common nesters and winter wildfowl visiting the great lake are more numerous and varied than at any other Lancashire water, he also showed a series of Dufay natural colour photographs taken at London Zoo this year and some scenes from Whipsnade Zoo, while the small herd of Chartley wild cattle there was compared with photographs of the original herd at Chartley Park, Staffordshire, now extinct, but of which Mr Hardy has two valuable photographs taken by a Liverpool naturalist in 1891 when the historic herd totalled 52 and tuberculosis had not then broken out At the Liverpool Cathedral Wild Birds' Sanctuary, said Mr Hardy, there is a resident population of a few blackbirds, greenfinches, song thrushes and wrens, but in winter chaffinches, great tits, cole tits and goldcrests visit it and during migration willow warblers are frequently heard, despite the sanctuary being in an old cemetery in the midst of city slums From this position inside the city valuable migration and other observations have been made as a refuting of the old belief of great migrations of city sparrows to distant harvest fields, but owing to the position of a new masons shed directly above the sanctuary, it has not been possible to attract many birds this year although the sanctuary is to be reconditioned and improved

Industrial Research in India

THE report of the Industrial Research Bureau, Government of India, for the year 1937–38 (Delhi Manager of Publications), covers the activities of the Industrial Research Council, the Industrial Research Bureau, which has been placed on a permanent basis as from March 1, 1938, and of the Research Branch of the Government Test House in the third year of its working Special attention has been devoted to the improvement of glass products and, in addition to the work in this field described in a separate chapter of the report, including the improvement of glass furnaces and a survey of glass making materials, the Council has authorized further work with an improved type of pot furnace The Research Branch of the Government Test House has been responsible for a considerable amount of work on paints, natural weathering and accelerated weathering tests and also on the construction and performance of dry cells Work has also been carried out on the use of vegetable oils as fuels and as lubricants for internal combustion engines, and promising results have been obtained with β naphthol diphenylamine, acetylphenylhydrazine and tin naphthenate as antioxidants in blends of castor oil with mineral oils Information on the manufacture of casein and casein plastics in India is being collected, and a number of investigations on oils and soaps have been allocated The report includes particulars of publications of the Bureau and of inquiries received

Research in Education in the United States

As a step toward canalizing research activities in the field of secondary education, much of which might otherwise run to waste, the United States Office of Education has published a bulletin on Needed Research in Secondary Education' (Washington, D C Supt of Documents Pp 70 Price 10 c) The bulletin is largely based on the monographs of the National Survey of Secondary Education, a collection of important research studies (more than 4,400 pages in all) relating to organization of schools, the pupil, administrative and supervisory problems and personnel, the curriculum and 'the extra curriculum Before proceeding to indicate specific problems needing investigation, the author discusses some general characteristics of contemporary methods of educational research, distinguishing, for the purpose of evaluating results three levels of quality the study of the results of practices (1) in any and all schools as found, (2) in schools selected for their outstanding merit, and (3) in experimental conditions set up especially for the purpose of testing theory He emphasizes the need for more co-ordinated and co operative research enterprises such as the college entrance inquiry, undertaken by the Progressive Education Association, into college entrance problems, in which three hundred colleges and thirty schools are participating Indications of specific problems needing investigation are given under twenty-five headings, corresponding with the several survey monographs already referred to; for example, individual differences, guidance, interpreting the secondary school to the public, and the library

Co operative educational research on an un precedented scale was undertaken in 1936–37 by sixty universities in the United States under what was known as the Project in Research in Universities of the Office of Education An important feature of the project was the widespread and co ordinated attack on each of forty selected problems by a number of universities at the same time The results of the investigations have been reported in a series of bulletins issued by the Office of Education An interesting example of these is Bulletin No 17 on Opportunities for the Preparation of Teachers of Exceptional Children (Washington, D C Super intendent of Documents Pp 58 Price 10 c) This gives a conspectus of courses concerning the education of eight different groups of exceptional children blind, deaf, crippled, delicate, speech defectives, mentally retarded, mentally gifted, and socially or emotionally maladjusted In recent years such courses have been characterized by an increasing breadth of the pre requisites for qualifying as a teacher of any one of these groups, candidates being required to have a general knowledge of the teaching methods appropriate for use with normal children and of the needs and problems of exceptional groups other than that chosen for special study Of the courses concerning the education of exceptionally gifted children, the report notes that "so little is known to day as to how gifted children should be educated that it is not surprising to find so few teacher education institutions presuming to tell their students in any intensive way how to do it"

Suggested New Peace Conference

The petition for the holding of a New Peace Conference open to all nations and directed towards remedying the economic and political conditions likely to lead to war, and urging the Government to take, in consultation with the President of the United States of America, the necessary steps to secure the holding of such a Conference, which has been sponsored by the National Peace Council, has received an excellent response Requests for more than 100,000 petition forms have been received from national organizations, most of which will go to local organizations The National Peace Council has also issued an appeal for the sum of £2,000 to liquidate an accumulated deficit and provide the expansion of income required for its growing work in mobilizing public opinion in Great Britain in support of efforts to lay the foundations of a general and durable peace

Activity of the Leonids

Mohd A R Khan Begumpet, Deccan, observed the Leonid shower this year on November 14–17, and found that it was more active than it has been for several years On the night of November 15, in spite of the fact that the radiant was close to the moon, between $21^h\ 30^m$ and $22^h\ 30^m$ U T , out of 31 meteors observed 14 were Leonids Several of them were bright, the magnitudes in some cases being 0 or even brighter, and most of them were followed by expanding streaks During the next half hour the numbers fell off, only two out of eleven meteors observed being Leonids On the following night, between $21^h\ 5^m$ and $22^h\ 35^m$ U T , out of 48 meteors observed, 12 were Leonids but on November 17, only two Leonids were observed out of a total of eight meteors between $23^h\ 30^m$ and 24^h U T The Leonid shower has been rather feeble for some years but this year it returned with surprising activity

Another Large Sunspot

Sunspot frequency remains high, and large spots within the range of naked eye vision have averaged, so far this year, one new group in about every ten days Very large spots, say of area greater than 1,000 millionths of the sun's hemisphere have been well represented, no fewer than thirteen having been recorded during the eleven months of 1938 A group of spots, first seen near the sun s east limb on Novem ber 23 in solar latitude 14° north grew rapidly in the next few days from 150 millionths to 1,950 millionths by November 27 The date of central meridian passage of this large group was November 28 8, and the west limb will be reached on December 5 On December 6, a region of the sun containing another large spot, which was developing during its approach to the west limb, will come into view again at the east limb

Announcements

The Buchan Prize for 1939 of the Royal Meteoro logical Society has been awarded to Dr E W Hewson, for papers contributed to the *Quarterly Journal* of the Society during the years 1933–37 dealing with The Application of Wet Bulb Potential Temperature to Air Mass Analysis"

The following officers for the session 1938–39 of the University of Durham Philosophical Society have recently been elected *President*, Very Rev C A Alington , *Hon General Secretary* Dr W A Clark *Hon Treasurer*, Mr J W Bullerwell , *Editor*, Prof G W Todd

An exhibition of optical aids will be held in Barnsley Grammar School on December 10 During the after noon, Mr H S Magnay, director of education, Barnsley, will speak on ' The Work of the British Film Institute ' Further information can be obtained from the Exhibition Secretary at the Grammar School

Dr Eugen Korschelt, emeritus professor of zoology and comparative anatomy in the University of Marburg, has been awarded the Goethe medal for art and science

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1000.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Further Evidence for the Radioactive Decay of Mesotrons

IT has been shown recently by Euler and Heisenberg[1,2] that the postulate that heavy electrons (or mesotrons as they seem to be finally named) are radioactively unstable, with a mean time of decay when at rest of about 2×10^{-6} seconds, is capable of explaining quantitatively the greater apparent absorption of penetrating cosmic rays in air than in dense materials.

Exactly the same considerations serve to explain the observations of Auger, Ehrenfest, Freon and Fournier[3], who measured the zenith angle distribution of the penetrating rays at different altitudes above sea level and found that the absorption of the inclined rays was greater than that of vertical rays under the same thickness of absorber.

Assume an isothermal atmosphere, so that the pressure will vary with the height z as $\exp(-z/z_0)$ where z_0 defines the rate of decrease of pressure with height. Let I_0 be the vertical intensity at sea level, and let I_1 be the intensity at a height z_1, in such a direction θ_1 from the zenith that the total mass of absorber is the same, so that θ_1 is given by $\cos\theta_1 = \exp(-z_1/z_0)$.

Following Euler and Heisenberg, we suppose that the mesotrons are produced by the incident primary rays after the latter have traversed a thickness of absorber equivalent to a fraction $f \approx 1/10$ of the vertical thickness of the atmosphere. Then the rays coming vertically downwards will be produced at a height z_m given by $f = \exp(-z_m/z_0)$ and those inclined at an angle θ_1 will be produced at a height z^1_m given by $f \cos\theta_1 = \exp(-z^1_m/z_0)$. Since the vertical rays traverse a path of length z_m to reach sea level, and the inclined rays a path $(z^1_m - z_1) \sec\theta_1$, to reach the height z_1, the excess path traversed by the latter is $l = (z^1_m - z_1)\sec\theta - z_m$. The relative intensity of the inclined rays to the vertical rays is then $I_1/I_0 = \exp(-l/L)$ where L is the mean range of the mesotrons before decay. Using the expressions given above for l, z_m, z_m^1 and θ_1, we obtain

$$\frac{I_1}{I_0} = \exp\left\{\frac{z_0}{L}\left(e^{z_1/z_0} - 1\right)\log f\right\}$$

From the meteorological data[7], we have $z_0 = 7.0$ km., and assuming $f = 1/10$ corresponding to a height of formation of mesotrons of 16 km., we obtain, using the observed ratios of I_1/I_0 taken from the data of Johnson[4] and of Auger and others, the values of L given below.

Height	(I_1/I_0) obs.	L calc.	Observer
1.9 km.	0.78	20 km.	Johnson
3.4 km.	0.69	25	Auger and others
		mean 23	

It has been further shown by Blackett[5] that the observed temperature coefficient α of cosmic rays can be explained as due to the greater vertical extension of a warm atmosphere, and should be given by the expression $\alpha = (dz/d\theta)/L$, where $dz/d\theta$ is the rate of increase with temperature of the layer of the atmosphere where the mesotrons are formed. Cosmic ray observations[6] give $\alpha = -0.18$ per cent per °C. and the meteorological data[7] give $dz/d\theta = 45$ m. per °C. for a height of about 16 km. Thus we get $L = 25$ km., in close agreement with the value of 24 km. found above for rays of about the same energy.

Consider now the observations of the mass absorption anomaly between air and water. The observed intensity under 60 m. water is one half that at sea level under the same mass of air, that is at an angle θ_1 such that $\sec\theta_1 = 6.0$. The height of formation of the rays, calculated as above, is 28.6 km. and so the difference of path between the inclined and the vertical rays is $28.6 \times 6 - 16 = 156$ km. This is the *half value* range, giving a *mean* range $L = 156/0.693 = 225$ km. The mean energy of the rays which penetrate 60 m. water can be estimated from the measured energy spectrum to be 3×10^{10} e. volts, while the mean energy of the rays at sea level is about 4×10^{9} e. volts.

We thus have two rough determinations of L for two different roughly estimated mean energies, E.

Experiment	L		E	L/E
Mass absorption anomaly	[illegible] km.		3 × 10^{10} e. volts	km. (e. volts)$^{-1}$ [illegible] 5 × $10^{[illegible]}$
Inclination anomaly	23	24 km.	4 × 10^{9} e. volts	mean	6 × $10^{[illegible]}$
Temperature effect	25			6.8 × $10^{[illegible]}$ km. (e. volts)$^{-1}$

If τ and τ_0 are the decay times of a particle of mass μ when at rest and when moving with energy $E \gg \mu c^2$, we have, from relativity considerations,

$$L = c\tau = \tau_0 E/\mu c$$

whence $L/E = \tau_0/\mu c$ = constant. This is seen to be approximately the case, thus verifying approximately the change of time scale of a moving particle.

The mean observed value of the constant gives $\tau_0/\mu = 1.29 \times 10^{19}$ sec./gm.$^{-1}$. It is thus the ratio τ_0/μ that is given directly by such experiments. To get τ_0, the mass must be assumed. Taking $\mu = 150\ m_e$, we get $\tau_0 = 1.7 \times 10^{-6}$ sec.

P. M. S. BLACKETT.

The University,
Manchester.

[8] Blackett, *Proc. Roy. Soc.*, A, **159**, 1 (1937).

IN a recent paper, Euler and Heisenberg[1] have thoroughly discussed the hypothesis that the hard component of the cosmic rays consists of 'mesotrons' produced in the upper layers of the atmosphere by primary electrons or photons and then disintegrating as predicted by Yukawa's theory of nuclear forces with a life time τ of the order of 10^{-6} sec. (τ is relative to a system in which the particle is at rest; whilst in a system in which the particle is moving with a velocity $v = \beta c$ the life time becomes[2] $\tau^1 = \tau/(\sqrt{1-\beta^2})$.)

In practice, the particles may disintegrate before they are brought to rest by ordinary loss of energy only in a gas, since in a liquid or solid absorber a 'mesotron' of a given velocity βc is stopped within a time which is very small in comparison with $\tau/(\sqrt{1-\beta^2})$. By traversing a gas absorber, the intensity of the hard component would therefore be more reduced than by traversing a liquid or a solid absorber of the same stopping power.

It has been pointed out that this theoretical result is confirmed by Ehmert's experiments, which give a difference of the kind expected between the absorption curves of cosmic rays in air and water[3].

In connexion with this, it is perhaps worth while to direct attention to some similar results previously obtained by De Benedetti and myself in Eritrea (geom. lat. 11° 30' N., 2,370 m. above sea-level)[4]. In these experiments the absorption of the cosmic particles was measured (*a*) in lead by interposing lead screens between two counters placed one above the other; (*b*) in air by inclining the counter system, thus increasing the thickness of the air layer traversed by the particles. In a first experiment each counter was surrounded by a cylindrical lead shield of 1.7 cm. thickness. Full absorption curves were taken; the lead curve begins with a steep decline (owing to the absorption of the soft component which is not completely cut off by the lead cylinders) but it then becomes nearly horizontal. The air curve on the contrary, descends smoothly, cutting the lead curve at about 120 gm./cm.^{2}.

In a further experiment, 4 cm. of lead was placed permanently between the counters (in addition to the lead cylinders) in order to avoid the disturbing effect of the soft component. One point only of each absorption curve was measured; namely, at 136 gm./cm.^{2} (12 cm.) lead and at 121 gm./cm.^{2} air (counter system inclined by 30°). The results were as follows:

		coin./min.
Counter system vertical	lead cylinders + 4 cm. lead	0.626 ± 0.009
	+ 4 + 12 cm. lead	0.575 ± 0.009
inclined	+ 4 cm. lead	0.516 ± 0.008

Both experiments show very definitely that the hard component is much more reduced by air than by lead. The difference would have been still greater in absence of the earth's magnetic field, which acts in the sense of diminishing the observed air absorption, as the counter system was inclined in a *westerly* direction. We may correct for the magnetic influence approximately by taking the average of the intensities in the western and in the eastern direction, which differ, under the actual experimental conditions, by a factor of about 1.2. We shall use, therefore, instead of the measured value 0.516, the corrected value $\frac{1.1}{1.2} \times 0.516 = 0.473$ for the frequency of the coincidences at 30°.

The difference between the air and the lead absorption, for which no satisfactory explanation had been found at that time, can now easily be accounted for on the disintegration hypothesis. The inclined rays have of course to travel a greater distance than the vertical ones before they reach the counters.

We assume that all the observed mesotrons are produced at a given depth R below the top of the atmosphere where R, as pointed out by Blackett[5], has to be measured in the actual direction of the incoming particles. The difference Δl between the paths of the particles which at an altitude of h km. above sea-level, are observed at a zenithal angle φ and in the vertical direction respectively, is then given by the formula

$$10^{-5}\,\Delta l = \left(\frac{10.33}{1.29}\log\frac{1033}{R} - h\right)\left(\frac{1}{\cos\varphi} - 1\right) - \frac{10.33}{1.29}\log\frac{\cos\varphi}{\cos\varphi}$$

Putting $h = 2.37$, $\varphi = 30°$ and taking for R the value corresponding to the maximum of the Regener–Pfotzer curve, namely, 100 gm./cm.^{2}, we get $\Delta l \sim 4 \times 10^5$ cm.

On the other hand, since the loss of energy by ionization is about the same in 121 gm./cm.^{2} of air and in 136 gm./cm.^{2} of lead, we may assume that the relative number $\Delta n/n$ of mesotrons which disintegrate by travelling the distance Δl is given by

$$\frac{\Delta n}{n} = \frac{0.575 - 0.473}{0.626} = 0.163$$

This result enables us to calculate the life time of the mesotrons. If we suppose, for reasons of simplicity, that they all have the same energy, say ε times the rest energy μc^2, with $\varepsilon \sim 40$, we have

$$\tau = \frac{\Delta l}{\beta c}\,\frac{n}{\Delta n}\sqrt{1-\beta^2} \sim \frac{\Delta l}{c}\,\frac{n}{\Delta n}\,\frac{1}{\varepsilon} \sim 2 \times 10^{-6}\ \text{sec.}$$

We obtain, therefore, a life time just of the order of magnitude previously given. Chiefly owing to the uncertainty in the value to be introduced for ε, the above estimate may be too low or too high by a factor 2.

Range of Nuclear Forces in Yukawa's Theory

FOUR years ago, Yukawa, in an attempt to develop a relativistic theory of the interaction of heavy particles in nuclei, was led to predict the existence of charged particles of mass intermediate between those of the electron and the proton[1].

In view of the great interest and hope raised by the striking discovery in cosmic rays of particles having just the desired mass, which one is naturally tempted to identify with Yukawa's particles, it may be desirable to have a derivation as elementary as possible of the fundamental relation

$$\rho = \frac{h}{mc}, \qquad (1)$$

where ρ is range of the nuclear forces, h is Planck's constant, m is the mass of the heavy electron'[1], c is the velocity of light, which led Yukawa to his remarkable prediction

It may perhaps be of interest therefore, to point out that the meaning of relation (1) may be simply illustrated by an argument based on Heisenberg's Uncertainty Principle, in close analogy to Bohr's discussion of Gamow's formula and other related problems

The argument runs as follows in Yukawa's theory the interaction between heavy particles is carried by the semi heavy particles, by means of simple emission and absorption processes (much in the same way as the relativistic interaction between two electrons can be described in terms of emission and absorption of light quanta), these are not, of course, actual emission and absorption processes, which would be contrary to the energy principle, they are called, therefore, virtual transitions Let us see, however, a little closer how it comes about that the energy principle is respected One might try to show that this is not so by setting up some device which could see the heavy electron whilst it is travelling from one heavy particle to the other In this case the energy principle can only be saved, as usual, if the uncontrollable energy exchange involved in the operation of the device is so large as to cover the energy excess actually observed, which is at least mc^2 Now the time t employed by the Yukawa particle in travelling from one heavy particle to the other is at least r/c, where r is the distance between the heavy particles The time of operation of the device must on the other hand be smaller than t (otherwise the system will react as a whole, and the device will not be able to detect the presence of the individual Yukawa particle), but it need not be essentially smaller than this We see, therefore, that the energy uncertainty will be, at most

$$\Delta E \sim hc/r$$

The condition

$$\Delta E > mc^2$$

actually gives the distance (1) as the limit up to which virtual transitions can make themselves felt without contradiction of the energy principle It may be remarked that by assuming a velocity of the intermediate particle smaller than c, it is only possible to reduce the energy uncertainty further, so that the consideration of relativistic velocities actually gives the optimum conditions or the upper limit to which the interaction may extend

I am very glad to express my thanks to Prof N Bohr for his kind interest and the Fondazione Volta of the C d R for a grant enabling me to stay in Copenhagen

Vector Maps as Positive Evidence in Crystal Analysis

THE principle of crystal analysis by means of vector maps may be indicated briefly as follows If the electron density throughout a crystal is expressed by a triple Fourier series ρ whose typical coefficient is the complex number a, the triple Fourier series V whose typical coefficient is the real number $|a|^2$ has two properties (1) the coefficients in V are determinable from and collectively resume all the information given by observations of intensities of reflected X rays, (2) a maximum value of V corresponds in position to a step between positions for which ρ is a maximum Since the points at which maximum values of ρ occur are the individual atoms, we can say that the observed data are made to furnish directly the vector map of the atomic structure The ultimate usefulness of the method depends, therefore, theoretically on the extent to which a vector map S_2 determines, or at least characterizes, the nuclear structure from which it is derived, practically on the efficiency of a mathematical technique for achieving such deduction as is theoretically within reach Until recently, it was thought that the direct value of the vector map was small and that the map was in effect only a test to be applied to structures suggested independently, and by showing that the main features of the atomic structure can be read from the map and that in many cases every detail of the atomic structure is implicit in the details of the map, Dr Wrinch has opened a new chapter in crystal analysis[1]

An argument has been used which purports to demonstrate without the trouble of examining specific instances that substantial reconstruction is theoretically impossible Since the vector series V is unaffected by a change in the angle of any coefficient a provided that the modulus $|a|$ is unchanged one series V is common to a multiply continuous infinity of density series ρ Therefore runs the argument every vector series must be common to an infinity of atomic structures, and we must accept the depressing conclusion that although an immense amount of toil has been devoted to collecting intensity observations and constructing vector diagrams for actual substances, this toil and the ingenuity and patience which have been needed for the discovery of structures compatible with the diagrams have alike been wasted since the probability that a particular structure found in this way is the correct one remains in any event negligibly small

When, however, we set to work actually to infer an atomic structure S_1 from a given vector map S_2 nothing is clearer than that the possibilities are finite and the probabilities far from zero A trivial example is in this respect typical the map which consists of the origin O, a single point A, and the image of A in O, is the map of a point pair congruent with OA, and cannot conceivably be the map of any other configuration Dr Wrinch is undoubtedly right the Patterson diagrams contain far more information than was suspected before she began to study the published insulin diagrams for herself In fact, reconstruction of a discrete point set from its vector map is a systematic process At various stages alternatives must be examined, but the analysis is exhaustive Sometimes it happens that a problem has two or more solutions, but geometrically this would seem to be a rare accident There are no parameters in the solutions The notion that the atomic structure remains hopelessly indeterminate however thoroughly the vector analysis is carried out is quite untenable; it is obviously absurd in the simplest cases, and gains nothing in plausibility when the map is complicated, for the number of conditions to be satisfied by the interatomic measurements rapidly outstrips the number of measurements available.

The explanation of the discrepancy is not hard to find. An arbitrary density series ρ does not represent even approximately the state of high concentration near isolated nuclei that we translate as an atomic structure. *Stringent conditions must be satisfied if* ρ is to correspond to a point set. If then the coefficients in ρ vary while the derived vector series V is unchanged this does not imply continuous variation of an atomic structure: it is only that the sharpness with which ρ represents such a structure is lost usually beyond discovery.

Experiment cannot furnish all the coefficients of an infinite series. In utilizing the observational data we have to be content with a vector series which is reduced to a small number of leading terms and with a density series which accounts for these leading terms. On any view we must regard a curtailed density series as nothing more than a useful approximation, and a point structure that would imply a discrete vector map is nothing less than another approximation which has an equal claim to consideration. But we must not think of the two approximations as exclusive alternatives. We can change from one form of approximation to the other halfway through a single investigation, and when we have been shown that discrete maps are decipherable we realize that this is just what we must do. Intensity measurements provide a V series; the V series provides a family of surfaces the nuclei of which constitute a set which from its physical origin must, within the observational limits of accuracy, be the vector map S_2 of some point structure S_1. The problem is now one for the mathematician, whose verdict on the evidence is final. If there is only one S_1 from which the S_2 is derivable, that S_1 is as perfect a picture of the atomic structure as the observations justify. Should there be more than one S_1, the problem remains open until reasons for discrimination are found, but such reasons must lie elsewhere than in the X-ray measurements. It should be added that while multiplicity of solutions is possible, the more elaborate the vector map the less is the likelihood of multiplicity. In other words, as the labour of proving the uniqueness of a solution becomes prohibitive, the probability that a structure which has the right map is the correct structure increases, and in the case of a megamolecule, if one atomic structure is shown to fit the facts exhibited in the vector diagrams, criticism which does not begin by providing another structure which also fits these facts need not be taken too seriously.

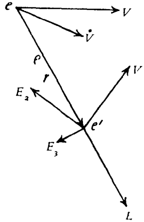
A Comprehensive Fundamental Electrical Formula

IN a letter on "Fundamental Physical Concepts" which appeared in NATURE of August 13, I suggested that it should be possible to dispense with magnetic considerations in fundamental physical theory, and to express the forces acting on elementary electric charges at rest and in uniform or accelerated motion by a single comprehensive formula; and I was very glad to learn from Mr. Rollo Appleyard's letter in NATURE of September 17 that Sir Horace Lamb had expressed the desirability of dispensing with the duality of electricity and magnetism. Such a formula has now been worked out and may be expressed most conveniently in the form

$$f = m\dot{V}' = Ee' = \frac{ee'}{r^3}\left\{\rho + ([V'[V\rho]] + [\rho[\rho\dot{V}]])/c^2\right\},$$

where f is the force on a charge e' moving with vector velocity V', due to a charge e moving with vector velocity V and acceleration $\dot{V}$, ρ is the vector distance ee' of length r, and c is the velocity of electric wave propagation in space. The charges e and e' and the electric force E are in C.G.S. electrostatic units, m is the total mass of e', including its 'electromagnetic mass', and the square brackets imply vector products.



The electric force E has three components $E_1 = \frac{e}{r^2}\frac{\rho}{r}$, which is obviously the electrostatic force in the direction of ρ; $E_2 = \frac{e}{c^2r^3}[V'[V\rho]]$ perpendicular to V' and in the plane $V\rho$, which represents the force on a current element $i\,ds = e'V'/c$ due to a current element $i\,ds = eV/c$ and is derivable from Ampère's experiments; and $E_3 = \frac{e}{c^2r^3}[\rho[\rho\dot{V}]]$ perpendicular to ρ and in the plane $\dot{V}\rho$ which is due to the electric wave excited by the acceleration of e. This last term covers current induction and leads directly to Neumann's inductance formula $M = \iint ds\,ds' \cos\epsilon/r$, but it has the advantage of giving the electric force E itself instead of its line integral round a closed circuit, and hence of being applicable to unclosed conductors. The accompanying diagram shows the three electric forces E_1, E_2 and E_3, when V, V', $\dot{V}$ and ρ are coplanar.

It will be noticed that no magnetic quantities whatever appear in the formula, as the permeability of space is implicitly included in the velocity $c = 1/\sqrt{\varkappa_0\mu_0}$, which is determinable by purely electrical measurements. If the charges e and e' are in a medium of relative permittivity $\varkappa$ and permeability μ, the formula becomes

$$f = Ee' = \frac{ee'}{\varkappa r^3}\left\{\rho + ([V'[V\rho]] + [\rho[\rho\dot{V}]])/v^2\right\},$$

where $v^2 = c^2/\varkappa\mu$, which introduces the permeability μ explicitly, as Mr. Appleyard suggested, but it need not be considered as a magnetic quantity as it is determinable by search coil methods which do not involve magnetic measurements It must be borne in mind, however, that all material media are aggregations of ions, each of which exercises its individual influence, so that this latter formula is only a convenient one for practical applications

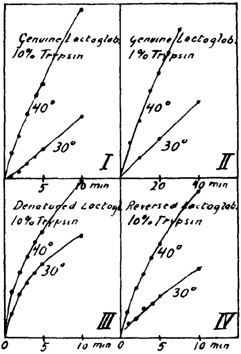
Peptide Bonds in Globular Proteins

IT is well known that genuine proteins (at pH 7) are attacked by crystalline trypsin which, on the other hand is able to split synthetic peptides This has been taken as support for the view that these proteins contain peptide bonds in their molecules[1]



We wish, however to point out that in the light of the following consideration, this support loses a great deal, if not all, its importance If, according to Anson and Mirsky denaturation is reversible, then in a solution of a given globular protein there is an equilibrium between genuine and denatured protein,

$$G \rightleftarrows D$$

Hence it is sufficient that D and only D should contain peptide bonds open to fission by trypsin, because by removal of D by hydrolysis this process is forced in the direction from left to right and G will gradually disappear as well The problem is open to experimental test in two different ways

(1) When the protein is hydrolysed with so much trypsin that the rate of the above process becomes the limiting factor in the total reaction, then we must expect the temperature coefficient for the hydrolysis to approach that of the reversible denaturation, which is presumably very high

(2) If a protein solution is heated for a short time to a temperature at which the process is proceeding rapidly and completely from left to right and then quickly cooled down to a temperature where it is a slow process a protein solution is obtained which contains initially more D than corresponds to the equilibrium at that (low) temperature Hence we may expect to find a more normal (that is, a lower) temperature coefficient for the hydrolysis of the protein in this solution Upon standing the equilibrium will slowly be reached and the temperature coefficient of the hydrolysis by much trypsin will tend to rise correspondingly

Some preliminary results are shown in the accompanying figure

(1) Equal volumes of 2 per cent lactoglobulin and 10 per cent trypsin (Merck) were mixed The reaction was followed by precipitation with trichloroacetic acid and the ordinates are the values for the nitrogen soluble in this acid The reaction temperatures chosen were 30° and 40°, pH was 7

(2) As (1) but with 1 per cent trypsin

(3) As (1), but the lactoglobulin solution was heated for 1 minute to 100° and rapidly cooled down again Trypsin was added immediately

(4) As (3), but the trypsin was added 20 hours later

(Commercial trypsin was used because it contained very little substance precipitable by trichloroacetic acid under the conditions applied In addition, it contained large quantities of enzymes which break down further the split products from the trypsin hydrolysis This is rather an advantage, since it is possible that these split products give precipitates with trichloroacetic acid)

(1) and (2) show that there is a small but distinct rise in the temperature coefficient of the initial hydrolysis rate, K with increasing trypsin concentration (1 per cent trypsin K_{40}/K_{30} 3 3, 10 per cent trypsin K_{40}/K_{30} – 4 3)

(1) and (3) show a pronounced fall in the temperature coefficient after the protein solution has been heated (K_{40}/K_{30} – 1 9) and cooled again

(3) and (4) show that this effect is partly reversible

These experiments provide sufficient basis for giving a warning against the conclusion that genuine proteins contain peptide bonds because they are split by proteinases like trypsin They give a certain indication that peptide bonds are formed or 'appear' (like SH groups) upon denaturation, but they are not conclusive enough to decide whether or not some hydrolysable peptide bonds are pre formed in the molecules of the genuine globular proteins

New Derivatives of the Silyl Radical

THE compound monochlorosilane, SiH_3Cl, prepared in 1919 by Stock, was shown by him to yield volatile monomeric derivatives in its reactions with water and ammonia With water it forms the compound $(SiH_3)_2O$, which is a gas, b p – 15 2°, and with ammonia the product is an amine-like body of the formula $N(SiH_3)_3$, b p + 52° This field appeared to us to be one which was capable of great extension and we have already made a number of interesting observations Thus we find that monochlorosilane reacts spontaneously and quantitatively with methyl amine according to the equation

$$3CH_3NH_2 + 2SiH_3Cl = CH_3N(SiH_3)_2 + 2CH_3NH_2HCl$$

The product, methyldisilylamine, is a liquid b p + 32 3°, which is stable in air, but is quantitatively hydrolysed by alkali its formula has been established by analysis and by vapour density determinations It differs from aliphatic amines in being quantitatively decomposed by hydrogen chloride

$$CH_3N(SiH_3)_2 + 3HCl = 2SiH_3Cl + CH_3NH_2HCl$$

Ethyldisilylamine, prepared by identical methods is a liquid of very similar properties boiling at + 65 9°

Trimethylamine and monochlorosilane have been found to combine in the cold in strictly equal volumes giving a stable solid quaternary compound $N(CH_3)_3SiH_3Cl$ This differs from the organic quaternary compounds in being instantaneously decomposed by water to form trimethylamine hydrochloride and disiloxane, $(SiH_3)_2O$ It is also decomposed on standing in moist air The ultimate products in this case are silicic acid and trimethylamine hydrochloride, but the intermediate products are soluble in water, giving solutions with strong reducing properties It is hydrolysed by alkali according to the equation

$$N(CH_3)_3SiH_3Cl + 3NaOH = Na_2SiO_3 + NaCl + N(CH_3)_3 + 3H_2$$

The dissociation pressure of the salt is 9 mm at 20° and this increases to one atmosphere at 91° The dissociation, however, is not reversible due to the disproportionation of the SiH_3Cl formed, thus

$$N(CH_3)_3SiH_3Cl \rightleftharpoons N(CH_3)_3 + SiH_3Cl$$
$$2SiH_3Cl \rightleftharpoons SiH_4 + SiH_2Cl_2$$

Trimethylsilylammonium chloride is a convenient silylating agent as the trimethylamine present will fix quantitatively any hydrogen chloride formed in a reaction Thus we have shown that it will react with alcohols to form volatile silyl alkyl ethers, which may be isolated with ease, for example

$$C_2H_5OH + N(SiH_3)(CH_3)_3Cl = SiH_3\,O\,C_2H_5 + N(CH_3)_3HCl$$

Monochlorosilane and dimethylamine react at room temperature with the production of the compound $N(SiH_3)(CH_3)_2$ This amine appears to form an unstable quaternary salt with excess of monochlorosilane There is thus a gradual decrease in the stability of these quaternary salts and we may formulate the following series

I	$N(CH_3)_4Cl$	Stable
II	$N(SiH_3)(CH_3)_3Cl$	Moderately stable
III	$N(SiH_3)_2(CH_3)_2Cl$	Unstable
IV	$N(SiH_3)_3(CH_3)Cl$	Not formed
V	$N(SiH_3)_4Cl$	Not formed

The members IV and V had they been formed, would have been detected in the preparation of the amines $N(SiH_3)_2(CH_3)$ and $N(SiH_3)_3$, since both of these preparations were carried out in the presence of an excess of monochlorosilane

We are at present extending these observations, and attempting to prepare compounds of the silyl radical with other elements, such as phosphorus, arsenic and lead

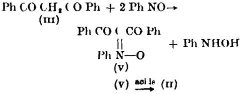
A Degradation Reaction in Organic Chemistry

THE method described below by means of examples enables the group CO CO CO or CO CH₂ CO to be converted into the dicarbonyl group CO CO which is virtually the degradation of a propane derivative into an ethane derivative

For example diphenyltriketone (I) is changed by warming with acids (for example, sulphuric acid acetic acid) into benzil (II)

$$\underset{(I)}{\mathrm{Ph\,CO\,CO\,CO\,Ph}} \xrightarrow{\text{acids}} \underset{(II)}{\mathrm{Ph\,CO\,CO\,Ph}}$$

The conversion of dibenzoylmethane (III) into benzil involves first the change of the group $\mathrm{CO\,CH_2\,CO}$ into $\mathrm{CO\,\underset{\overset{\|}{N}}{C}\,CO}$ (IV) and then warming the resulting product with acids (for example sulphuric acid acetic acid) The nitrogen containing intermediate compound with the group (IV) may be (V) which is readily obtained in half an hour by the action of (III) on nitrosobenzene in alcohol Diphenyltriketone 2 anil oxide (V)[1] forms yellow crystals m p 144°



$$\underset{(III)}{\mathrm{Ph\,CO\,CH_2\,CO\,Ph}} + 2\,\mathrm{Ph\,NO} \rightarrow \underset{(V)}{\mathrm{Ph\,CO\,\underset{\overset{\|}{Ph\,N—O}}{C}\,CO\,Ph}} + \mathrm{Ph\,NHOH}$$

$$(V) \xrightarrow{\text{acids}} (II)$$

Kinetics of Exchange Reactions

THE shape of the curve obtained by plotting the concentration of a reactant or product against the time can in general be used to yield information about the way the rate of the reaction depends on concentration in particular about its order In the case of isotopic exchange reactions this is not possible even in principle supposing the isotopes to have identical chemical properties This rather amusing result does not appear to have been placed on record hitherto

Suppose the reaction is

$$AX^* + BX = AX + BX^*,$$

where X^* represents a labelled (for example, radioactive) X atom. Let the concentrations be AX, a BX b, AX^*, x and BX^*, y, if the compounds contain several similarly situated X atoms, these concentrations must be expressed in equivalents of X We will assume that $a \gg x$ and $b \gg y$ Let the exchange proceed at a rate

$$R = k\,f(a)\,\varphi(b),$$

where f and φ are *any* functions and k is a constant Then

$$\frac{dx}{dt} = -\frac{dy}{dt} = -\frac{x}{a}R + \frac{y}{b}R,$$

where t is the time If $x = 0$ when $t = 0$, and $x = x_\infty$

when $t \rightarrow \infty$, these equations can be integrated to give

$$-\ln\left(1-\frac{x}{x_{\infty}}\right)=R\left(\frac{a+b}{ab}\right)t$$

Thus the shape of the x t – curve is given *exactly* by simple theory, and is independent of the form of R, whether the reaction is uni , bi or termolecular, or something more complicated, the x t – curve is that for a reversible unimolecular reaction

The reason for this particularly simple result is, of course, that the composition of the reacting mixture remains chemically unchanged throughout the reaction, so that we get $k\frac{x}{a}f(a)\varphi(b)$ instead of $k f\left(\frac{x}{a}\right)\varphi(b)$ for the rate of the forward reaction and a similar expression for the rate of the backward reaction By changing a and b we can of course, determine $f(a)$ and $\varphi(b)$, that is determine the order of the reaction

Manifold Effects of Male and Female Sex Hormones in both Sexes

IN our previous experiments[1] the hormones were usually injected into gonadectomized rats for a period of 21 23 days This comparatively short treatment produced definite effects on the non sexual organs (except spleen) of males, but the effects were less evident or absent in most of these organs in females

In the present experiments, 91 castrated and 88 ovariectomized rats have been injected for a period of 2½ to 4 months with the following hormones and doses (per week) androsterone 7 5 mgm , trans dehydroandrosterone 7 5 mgm testosterone propionate 0 75–7 5 mgm , and (in males only) testosterone 0 75 7 5 mgm , alone or simultaneously with œstradiol dipropionate, 0 018 0 200 mgm , our usual experimental technique being used[1]

The effects obtained on the organs investigated were very similar in males and females, varying as a rule only in degree The accompanying table containing, for the sake of economy of space, the average weights of some organs only, gives examples of the changes observed in females

Hormone injected		Actual weights of organs			
Male hormone (mgm per week)	Œstradiol dipropionate (mgm) per wk	Hypophysis (mgm)	Liver (gm)	Heart (mgm)	Gain in body wt (gm)
None (control rats)	none	11 9	8 31	737	165
None	0 090	98 0	7 61	623	73
None	0 200	132 2	6 77	596	13
Androsterone 7 5	none	10 8	11 39	928	199
Androsterone 7 5	0 090	48 0	8 96	723	112
Testosterone prop 2 25	none	10 9	10 42	935	139
Testosterone prop 2 25	0 200	00 2	7 91	621	64

Some important conclusions are obvious from the data given in this table and from the other results (not given here) obtained with females and males

(1) While œstrogens produce *stunted growth* and decreased *fat deposition*, with the male hormones this depressing effect is absent or (with large doses of testosterone propionate) slight

(2) Moreover, this depressing effect of œstrogens is to some extent neutralized by the simultaneous injections of male hormones (except dehydroandrosterone), thus indicating some antagonistic relation between œstrogens and male hormones (see table)

(3) Both male and female hormones accelerate the physiological involution of the *thymus*, having a co operative effect on this organ, when injected simultaneously

(4) The male hormones have a definite effect on *adrenals* in males causing the hypertrophied castration glands to return to or towards normal The histological changes which occur have been discussed elsewhere (Hall and Korenchevsky[2]) Simultaneous injections with œstrogens in most cases prevent this restorative effect on size and weight of adrenals In females, similar results have been obtained with androsterone, but the effects of the other hormones and of ovariectomy were indefinite

(5) While male hormones do not produce any considerable change in weight of the *hypophysis*, certain doses of œstrogens cause a tumour like hyperplasia of the gland (see table) When injected simultaneously, male hormones neutralize to a considerable extent (in one male rat almost to normal—14 mgm) this hyperplastic effect of œstrogens both in males and (see table) in females This is another important case of antagonistic relations between male and female hormones

(6) Slight hypertrophy of *liver*, *kidneys*, *heart* and *spleen* in gonadectomized animals is produced by male hormones, while œstrogens cause either a decrease in their actual weight or no change (kidneys), This effect of œstrogens is in some organs partly dependent on the body weight, which relation, suggesting a possible stimulating effect on the kidneys, will be discussed elsewhere When injected simultaneously the effect of male hormones on the actual weights of these organs is antagonistic to, and to some extent neutralizes, that of œstrogens in both sexes (see table)

The data presented (1) confirm a definition, previously given[3], of gonadal hormones as not merely sex hormones, but as hormones also possessing manifold important effects on non sexual organs , (2) show the co operative and antagonistic interrelations between male and female hormones, supplementing similar results previously obtained[1] on sexual organs

Antarctica and Glacial Ages

IN NATURE of September 17 there is an interesting discussion between Rev W S Fleming and Prof E W MacBride in regard to the Gondwana flora and glaciation in Antarctica in Permo-carboniferous times which requires some comment Referring to the Permo carboniferous ice age, Prof MacBride suggests that a vast Gondwana continent in temperate parts of the southern hemisphere drifted south across the south pole, Australia and Antarctica, which lay at its north edge, being left behind in temperate latitudes The rest of the continent underwent severe glaciation and finally broke up into South America, South Africa and the Deccan of India

Why Australia, which was heavily glaciated, was left behind is difficult to understand unless it was because the Australian geologists interpret their tillites as due to the work of floating ice It Australia in temperate latitudes was severely glaciated, why was it necessary for the other glaciated regions to be bundled together and drifted across the pole ?

In reality, all the heavily glaciated regions were close to the sea and a compact Gondwanaland certainly did not exist while glaciation was going on The Indian tillites are associated with marine beds at two points hundreds of miles apart The South American tillites are found with marine deposits both in Brazil and on the western side, and in South Africa on its south western side its ice sheet reached the sea (See Ice Ages Recent and Ancient pp 102 3, 134, 146–9, 168) This of course is what one should expect since the building of an ice sheet demands an immense amount of evaporation from some nearby body of warm water In the Pleistocene north western Europe and north eastern America near the Atlantic with its Gulf Stream were heavily glaciated while Siberia one of the coldest parts of the earth had no important ice sheet A huge land mass, such as the supposed Gondwanaland, even at the south pole, would lack precipitation in its central parts, and so would be unglaciated

Late Palæozoic glaciation in Australia deserves some further mention The geologists of the Commonwealth have proved that there were two important glaciations, one in the Carboniferous the other much later, separated by a very long interglacial time when great coal seams were laid down Are we to suppose that Australia was pushed towards the south pole in the Carboniferous and then pulled up to a temperate latitude for coal plants to grow, and then pushed down again for the second glaciation?

Also what about the Permo carboniferous tillites at Squantum near Boston and on the Alaskan boundary in North America and the glacial deposits described in France and Germany ? Surely Gondwanaland had nothing to do with these deposits in the northern hemisphere

In a great ice age like the Pleistocene and the Permo carboniferous, the whole world is chilled, though great ice sheets are formed only in regions favourably placed for moisture laden winds to deposit snow

May an old fashioned geologist ask the advocates of drifting continents how they account for the extraordinary performances they so readily assume ? On the Labrador coast one may see icebergs pushing southward, thrusting aside the ice floes, or sometimes ridging them up in front, but one knows that the greater part of the berg is sunk in the arctic current, so that the motion is accounted for

Our iceberg like continents are solidly frozen into the sea bottom crust, supposedly miles in thickness of strong basalt Are there currents in the supposedly plastic basic substratum in which the bulbs of the continents are enclosed ? Or what forces push them in one direction rather than another ? To say they 'drift' is, of course, begging the whole question Permanently enclosed rock masses cannot drift— they must be pulled or pushed What power do the advocates of the 'drift of continents' suppose dragged India from the antarctic regions thousands of miles north, over the bulge of the equator, to leave it in the northern hemisphere ? Where are the heaped up ridges of rock which it thrust up on each side, and where is the scar it left after its passage ? Again, why did Gondwanaland explode and send South America in one direction and South Africa in another and leave Antarctica where it is ?

These casual driftings of massive blocks of the earth s solid crust should have some reasonable explanation before being used to account for the distribution of plants or animals The Gondwana plants are mainly ferns equisetums and club mosses especially ferns all cryptogams the spores of which could easily be transported by the wind A gale would quickly carry them hundreds of miles Why send continents crashing through the solid earth s crust to effect their distribution ?

Formation of Widmanstatten Figures in Meteorites

Investigations have been conducted in this laboratory during the last few years on the structure of artificially prepared iron nickel alloys in the iron end of the equilibrium diagram, and during the last year the structure of iron nickel meteorites has also been examined An interesting point in connexion with meteorites is the formation of etched patterns known as Widmanstatten figures Several attempts have been made to explain these figures, but no satisfactory theory seems, so far, to have been advanced

I wish to mention here certain conclusions reached in the course of the investigations referred to, which may be helpful in arriving at a satisfactory explanation of the existence of these figures

(1) An iron nickel alloy containing say between 6 and 25 per cent of nickel, when quenched from high temperature, consists solely of a distorted body centred lattice which is in metastable equilibrium at ordinary temperatures It is suggested that this is the condition of meteoric iron nickel after the sudden drop in temperature which occurs when the meteorite comes to rest in the earth, and that afterwards prolonged annealing at a comparatively low temperature has taken place

(2) The alloy possessing as it does a distorted lattice, is supersaturated with nickel The result of this is that internal stresses exist in the material This condition is favourable to the growth of single crystals when the material is annealed and this growth may take place at moderately low temperatures

(3) The growth of the crystals occurs in sheets parallel to the octahedral planes of the distorted lattice, the growth being much more rapid in the direction of the octahedral plane than at right angles to it These crystals are the stable kamacite or undistorted α lattice the composition of which corresponds with that at the pure α phase boundary at the temperature of annealing

(4) During the process of crystal growth, the surplus nickel in the lattice is gradually displaced and collects on the surfaces of the kamacite sheets When the concentration of nickel reaches a certain value, tænite is formed Thus tænite appears in the form of very thin sheets bordering crystals of kamacite It may be expected also, that as the result of this process, a definite relation exists between the orientation of kamacite and tænite crystals Different observers have found this to be the case

(5) The lower the nickel content of the alloy as a whole, the greater is the width of the kamacite plate, because more volume of kamacite will have to be formed in order to expel a sufficient number of nickel atoms to produce tænite at the boundary This explains the different degrees of 'coarseness' found in meteorites (octahedrites)

(6) Meteorites within a certain range of composition generally contain plessite, which may consist of a microscopic octahedral arrangement of kamacite and tænite, or may be of a granular structure similar to that of the metastable distorted α alloy When the plessite is in the latter form the meteorite has not reached its final state of equilibrium a conclusion which may appear strange when, to quote one writer, meteorites have presumably had geological ages in which to reach equilibrium But according to the views expressed here, any equilibrium which might have been established would be upset by the final heating of the meteorite in passing through the atmosphere and in penetrating the earth's crust, followed by sudden cooling

(7) If plessite may be regarded as consisting only of the metastable distorted α lattice, it should not exist in an alloy which has reached its final and true state of equilibrium, this state consisting only of stable kamacite and tænite

The above general statements will be amplified and supplemented by experimental data in a series of papers which will shortly be published

A Visual Phenomenon

ON starting an electric fan with the observer so placed that he can see the sky (or other bright background) through the vanes of the fan, then at a certain speed of rotation a hazy violet patch of colour can be seen in the plane of the fan At higher rates of rotation the effect disappears, but can again be observed on decreasing the speed to the critical value The speed in question appears to correspond with the frequency of flicker The effect was actually observed in the case of a fume cupboard extractor fan

Points from Foregoing Letters

PROF P M S BLACKETT calculates the mean range of the mesotrons (particles of mass intermediate between that of the electron and that of the proton) from the relative intensity of the inclined cosmic rays to the vertical rays, and also from the absorption anomaly between air and water He arrives at a value of $1\,7 \times 10^{-6}$ sec for the decay time of a fast moving mesotron, assuming its mass to be 150 times that of the electron Prof B Rossi obtains a value of the same order of magnitude for the life of the mesotron from calculations based upon the anomaly of absorption of cosmic rays by air and by lead when vertical and inclined counters were used

A simple demonstration of Yukawa's relation $\rho = h/mc$, from which the existence of particles of intermediate mass (mesotrons) was inferred, is given by Prof G C Wick, based upon Heisenberg's Uncertainty Principle

When inferring crystal stucture from X ray vector maps possibilities are finite, according to Prof E H Neville It is rare that two or more solutions are possible, especially in the case of a megamolecule If one structure is shown to fit the facts exhibited in the vector diagrams, any serious criticism must begin by providing an alternative structure that fits the diagram

A fundamental electrical formula which expresses the forces acting on elementary electric charges at rest and in uniform or accelerated motion, without introducing magnetic quantities (thus dispensing with the duality of electricity and magnetism), has been worked out by Dr C V Drysdale

The fact that genuine proteins are split by proteinases (such as trypsin) does not prove that they contain peptide bonds, according to Dr K Linderstrøm-Lang, R D Hotchkiss and G Johansen A small but distinct rise in the temperature coefficient of the initial hydrolysis rate with increasing trypsin concentration and a pronounced fall in the coefficient when the protein has been first heated to 100° C and then cooled, indicate that peptide bonds appear upon denaturation, but may not have existed in the original protein

The preparation of certain monomeric compounds of silicon of a new type, containing both silyl and alkyl radicals, is announced by Dr H J Emeléus and N Miller A quaternary salt, trimethylsilyl ammonium chloride, containing such radicals, is also described , and its behaviour is compared with that of its analogues

Prof A Schonberg describes a method by means of which the group CO CO CO· or CO CH_2 CO may be converted into the dicarbonyl group CO CO , which is virtually the degradation of a propane derivative into an ethane derivative

H A C McKay points out that in the case of isotopic exchange reactions, where the isotopes have identical chemical properties, it would not be possible, even in principle, to determine the order of the reaction from a single concentration time curve

The effect of male and female sex hormones upon various organs (liver, heart, adrenals) of castrated or ovariectomized rats, is described by Dr V Korenchevsky and K Hall They show that the hormones produce manifold important results upon the non sexual organs and that the male and female hormones have sometimes co operative, and in other circumstances antagonistic, effects

Prof A P Coleman doubts Prof MacBride's hypothesis of a Gondwana continent having drifted across the South Pole in Permo Carboniferous times, and supplies alternative explanations for the glaciation effects observed in some of the Permo Carboniferous rocks of the southern hemisphere

Research Items

Canoes of the Pacific

IN the third and final volume of their study of the canoes of Oceania (Bernice P Bishop Museum, Honolulu, *Special Publication* 29), Dr A C Haddon and Mr James B Hornell deal with definitions of terms, a general survey and conclusions It appears likely that the Papuans originally were acquainted only with the raft or simple dugout, possibly with a makeshift sail of palm leaves The first wave of Indonesian migration into Melanesia may have brought the canoe with double outrigger with parallel, or stick connexions It was possibly square sail rigged, with mast yard, or boom Later immigrants came with large double sailing canoes and sailing canoes with small outrigger with stick connexions for the booms Probably they were rigged with some form of the Oceanic sprit sail These are the proto Samoans of Churchill, the most ancient stratum of central and western Polynesia—the first Kava people The later Kava peoples also had large sailing double canoes and large single outrigger canoes with stick and stanchion connexions Their dugouts doubtless had strakes, which led to the plank built boat The true plank built boat was employed only sporadically in western Oceania and is not a local development It belongs to one of the later spreads from the West into Polynesia The later Kava peoples, or some of them, the so called Tangaroans, were instrumental in raising Polynesian culture to its highest level The Tangaroans were also great navigators, and it may be under them that New Zealand was colonized by the Fleet" in A D 1350 The migration of the betel people into Melanesia was probably the last of these great movements, and to them the introduction of the various types of plank canoe, without outrigger, was due The abandonment of the outrigger by the Maori was probably a local development The colonizers of Hawaii, who brought a double canoe and a single outrigger probably came direct through Micronesia about A D 400 450

The Dionne Quintuplets

THE unique Dionne quintuplets are being studied genetically Dr John W MacArthur presents the evidence (*J Heredity*, 29, No 9) that they represent a monozygotic set The methods in use for twins have been applied to them Employing the diagnostic criteria for distinguishing between identical and fraternal twins, each method, as well as the new quantitative method from dermatoglyphics, leads to the conclusion that they are monozygotic There was evidently a single placenta and chorion, and probably five separate amnia and five cords attached in a ring There may have been a sixth embryo which aborted very early The children themselves and their nurses can recognize each of the five, but their facial features are very similar The other sibs vary widely in hair colour, hair shape, eye colour, features, ears, etc The finger prints of the quintuplets are as like as in most identical twins, the palm and sole prints repeating some rare features, all ten feet have a mild syndactyly of the second and third toes and a peculiar thenar pattern complex They are of the same blood group and very similar in eyes, hair and ears When compared in pairs, no one stands apart from the rest, nor is any pair exceptional It appears that forty five cases of quintuplet births have been recorded in the literature, and at least two or three sets were monozygotic but in this case alone have all survived

Kinetics of Choline Esterase

THE kinetics of the enzyme which splits acetyl choline in the body, choline esterase, have up to the present only been studied on relatively high concentrations of acetylcholine In the organism acetylcholine is active in very minute amounts, and for this reason, some knowledge of the effects of esterase on low concentrations was desirable Clark, Raventos Stedman and Stedman (*Quart J Exp Physiol* 28 77, 1938) find that, in general, the hydrolysis of acetylcholine by choline esterase follows the usual course of an enzymic reaction When high concentrations of the substrate are present, the amount hydrolysed per second is constant, but when the concentration falls below 5×10^{-5} molar, the amount of acetylcholine hydrolysed is approximately proportionate to the concentration Estimations of the effect on the hydrolysis of variations in the concentration of esterase show that, in all probability, the amount destroyed in unit time varies as the esterase concentration, and that there is no reason to suppose that the rate of hydrolysis increases as some power of the enzyme concentration Taking these points into consideration, the authors believe that in the animal organism the hydrolysis of even minute amounts of acetylcholine is likely to take at least as long as 0 1 sec

Fossil Penguin in South Australia

FROM Miocene beds in the cliffs on the east shore of St Vincent's Bay, South Australia, H H Finlayson describes a single bone of a penguin (*Trans Roy Soc S Australia*, 62, 14, 1938) The bone, a left humerus complete except for the tuberculum externum, was accompanied by several fractured laminæ probably derived from a radius Among the thirty five species of fossil penguins now known the Australian humerus corresponds most closely in dimensions and structural detail with that of *Palæeudyptes antarcticus* which was found in beds of similar age in New Zealand But the author considers that the variation shown in the humeral characters of penguins and the uncertainty of conclusions as to relationship to be drawn from geographical distribution, until such time as the original centre of distribution is known, precludes the application of a new name to the Australian fossil The fact that the Tertiary penguins of the Antarctic region show structures which seem to indicate superior terrestrial and inferior aquatic adaptations, according to Lowe, suggests that these forms were comparatively sedentary and coast frequenting, and this would preclude colonization over long stretches of open sea

Moisture Conditions within Termite Mounds

IN Pamphlet No 82 of the Council for Scientific and Industrial Research in Australia, Messrs R V Fyfe and F J Gray give an account of the humidity of the atmosphere and the moisture conditions within mounds of the termite, *Eutermes exitiosus* After a study of the structure of different mounds, and of the composition of the different walls comprising these mounds it is shown that the termites have developed an extraordinary construction whereby they maintain particular moisture conditions These conditions prevail in the interior of the mounds and are necessary for the maintenance of the termite colony They are, furthermore maintained throughout all conditions of temperature and rainfall which may occur outside the mounds The structure and composition of the walls of the mounds are stated to be such as to retain the moisture produced as the result of the respiration of the termites The temperature maintained by the living insects, and the special properties of the mound material, prevent the deposition of this free water where the termites generally live The mound is, it seems, so constructed as to allow the amount of water production by breathing and that lost by diffusion and evaporation to be closely balanced

Cereal Synonyms

THE Cereal Synonym Committee regards two cereals as synonymous when they present precisely similar morphological characters, and when they also possess identical physiological characters in so far as they can be determined Even then, by this term they do not necessarily imply that these two varieties are of identical origin, though doubtless in the majority of cases they are The possibility of two cereals of different parentage presenting such a close, if not complete similarity as to mask their individuality has not been lost sight of But the Committee has to deal with facts as they are, therefore, it regards as synonymous all cereals which are identical in the sense used above even when it is known that the origins are different It should be noted, however that before the Committee comes to a conclusion concerning the synonymity of any variety, the breeder and/or the introducer is given an opportunity of demonstrating to the Committee such differences as he may claim to exist between his variety and the type variety On the basis of this definition, the Committee has reached certain decisions on the stocks examined in 1937 *Westerfield White* is considered a synonym for *Setter*, and two wheats of continental origin introduced as Hybrid 40 and Desprez 80, but which have since been renamed in other countries, will be known as Hybrid 40 (Benoist) and Desprez 80 (Jonequois) The latter is a very early ripening short strawed variety among those recommended for good soils by the National Institute of Agricultural Botany, in Farmer s Leaflet No 1 *Holdfast*, however, is worthy of special attention in the early ripening group as baking quality is likely to assume greater importance than heretofore, and tests have shown it to be superior to the *Yeoman* in this respect Early sowing is stressed in the case of the later ripening varieties As regards oats, the new Aberystwyth *White Winter Oat S* 147 is suitable for fertile soils, where *Grey Winter* is likely to lodge *Plumage archer* and *Spratt archer* are still the most favoured barleys Particulars of other good varieties of autumn sown cereals and the special purposes for which they are adapted, can be obtained on application from the Institute at Cambridge or from any county agricultural organizer

Hybrid Vigour in Wheat

A STUDY of heterosis or hybrid vigour in wheat has been made by Dr B P Pal and Mr N Alam (*Proc Ind Acad Sci*, 7, No 3, Sec B) They crossed a bearded with a beardless variety of *T vulgare* from Pusa and compared the F_1 with the parents as regards amount of germination, rate of formation of first leaves, height, tillering, number of leaves, length of ear, number of fertile spikelets, number of grains per ear, weight of grain and yield A new feature of these experiments was that these comparisons were made when the three crops were grown under different sets of conditions Heterosis was found, less striking than in maize, and its amount was shown to vary according to the conditions Thus by sowing at different depths it was found that the F_1 germination was superior only at depths of 4–6 in The time of sowing (morning, noon or evening) also affected the germination rate The difference in tillering between the F_1 and the better parent was greater in sowings made early in the season than later, the percentage in favour of the F_1 ranging from 46 per cent to nil In ear characters the F_1 exceeded the mean of the parents under all conditions but were not significantly better than the better parent The results indicate that the expression of heterosis is much influenced by various external factors, and that the optimum conditions for its expression in any particular cross therefore need to be sought

Fertility of Amphidiploid Hybrids

H W HOWARD has made a study of the fertility of amphidiploid hybrids between the radish and cabbage in F_3 and F_4 generations (*J Genetics*, 36, No 2) Earlier studies of this cross have been made by Karpechenko and Richharia Fresh F_1 hybrids were also studied and were found to be of two types One type had short meiotic chromosomes like the parents, the other had long chromosomes A variable number of bivalents and occasional trivalents were formed The chiasmata gave evidence of a reduplication in one chromosome Some secondary pairing of univalents was observed, as well as bridges and restitution nuclei The theory of fertility in amphidiploids is considered, and it is pointed out that the types of F_1 pairing may lead to the formation of gametes which have some chromosome segments reduplicated and others deficient Some of the resulting offspring may not be true amphidiploids and these will show reduced fertility Some F_4 plants had a much higher fertility, others equal or lower fertility than the F_3 The increased fertility is attributed to the elimination of irregular chromosome pairing Certain F_3 plants had less than 36 chromosomes

A New Species of Fungus

Tremella translucens is the name suggested for a new fungus species described by H D Gordon (*Trans Brit Mycol Soc*, 22, Pts 1 and 2, Aug 1938) The fructification is a small cushion, not usually more than 2 mm in diameter, upon dead pine needles Basidia are quite characteristic of the genus, being divided longitudinally to the base Dry fructifications have basidia without spores, but on wetting, they form epibasidia and basidiospores The new species belongs to the section Tuberculiformes of the genus *Tremella* Only three species of the section are European, and differ sharply from *T translucens*, which therefore seems to have a good title to specific rank

The Violent Earthquake of November 10

Very large amplitudes were registered on the seismograms for this shock at Hamburg and Stuttgart, described in Nature of November 19 p 909 At Hamburg a small primary pulse was discernible at 20h 30m 0s a dilatational *P* wave at 30m 8s and *S* at 39m 41s At Stuttgart a compressional *P* wave was registered at 20h 30m 29s, *S* at 40m 17s, *PS* at 41m 5s and *L* at 52m From Hamburg the epicentral distance was thus 8 400 km and from Stuttgart 8,500 km The azimuth from Stuttgart was N 5° E All this evidence supports the hypothesis of an epicentre in the North Pacific Ocean in the neighbourhood of the Bering Sea and the Aleutian Islands

Determination of Nicotinic Acid and its Amide

Recent work on vitamins has shown that nicotinic acid and nicotinamide cure pellagra in human beings and thus act as anti pellagra vitamins It is therefore of importance to discover a method of determining and detecting those pyridine derivatives when they occur in traces Karrer and Keller (*Helv chim Acta*, 21, 463, 1938) worked out a colorimetric method based on the reaction between 2 4-dinitrochloro benzene and pyridine discovered by Vongerichte in 1899 In alkaline solution a deep red colour is produced The method has been used by Karrer and Keller for the determination of nicotinamide in the liver of various warm blooded animals König, in 1904, described a colour reaction of pyridine and its derivatives which depended on the fission of the pyridine ring by cyanogen bromide On addition of aromatic amine, a yellow to yellowish green colour is produced Swaminathan has recently used this reaction (Nature, 141, 830, 1938) to determine nicotinic acid in foodstuffs H Kringstad and T Naess (*Naturwiss*, 26, 709, 1938) have now reported further investigations on this reaction They find the intensity of colour is considerably affected by hydrogen ion concentration By buffering the solution at *p*H 6 1 by a phosphate buffer, and determining the colour intensity when it has reached its maximum (after 7 min in the case of nicotinic acid) by the extinction method, it is found that the extinction coefficient is directly proportional to the concentration of the pyridine derivative It is possible by this method to determine nicotinamide in concentration so low as 1 γ per c c The shade and intensity of the colour vary with the pyridine derivative used, but the proportionality referred to above holds in all cases

Free Radicals from Toluene

There are three possible modes of decomposition of the toluene molecule on heating (900–1,100°, 0 1–0 5 mm)

(1) $C_6H_5\,CH_3 \rightarrow C_6H_5CH_2- \; + H$

(2) $C_6H_5\,CH_3 \rightarrow o$ and p $CH_3C_6H_4- \; + H$

(3) $C_6H_5\,CH_3 \rightarrow C_6H_5- \; + CH_3-$

F Hein and H I Mesée (*Naturwiss*, 26, 710, 1938) have investigated this thermolysis by a method similar to that used by Rice, the free radicals formed being removed by combination with mercury vapour It has been found that the reaction gives rise entirely to benzyl radicals The compound $(C_6H_5\text{-}CH_2)_2Hg_2$ is formed by the combination of the benzyl radicals with the mercury vapour followed by polymerization This compound is stable at liquid air temperatures, but is decomposed on warming to room temperature giving mercury dibenzyl $C_6H_5CH_2HgCH_2C_6H_5$ and mercury It therefore appears that the thermal decomposition of toluene at about 1 000° and at low pressure takes place entirely according to the first reaction mentioned above

Sound Insulation

In a communication to the Physical Society on October 28 Dr J L R Constable of the National Physical Laboratory gave the results of his measurements of the sound insulating powers of various walls and floors of buildings In one case a set of six rooms in two stories, rooms 1 2 and 3 in the upper, 4, 5 and 6 in the lower, about 14 ft wide 27, 16 and 18 ft long respectively were used Rooms 1 and 2, and 4 and 5 were separated by a plastered 9 inch brick wall, and 2 and 3, and 5 and 6 by a 3 inch plastered clinker concrete wall The side walls were on one side a 2 inch cavity single brick wall and on the other a plastered 3 inch hollow tile wall The floors were all 5 5 inch reinforced concrete A warbling note of frequency 200, 700 or 2 000 was generated in room 2 and the intensity of the sound in the other rooms measured The reduction of intensity was greater for the high than for the low pitched note The average reductions were in room 1, 45 decibels, 3 40 db 5, 47 db 4 and 6, 52 db The brick wall between rooms 1 and 2 would produce a reduction of 55 db and the clinker wall between rooms 2 and 3, 43 db The difference between these results and those found in the rooms is due to the transmission through the side walls the floors and ceilings of the rooms In average buildings there is therefore little to gain by partitions producing greater reductions than 55 or 60 db unless the side walls are improved to a corresponding extent

Distance Geometries

One of the best known geometrical theorems is that any two sides of a triangle are together greater than the third From this simple basis an extensive set of distance geometries has been developed. Prof L M Blumenthal (*Univ Missouri Studies*, 13, No 2, 1938) gives an account of these They are based on abstract postulates, with a single completely undefined element *point* and a single numerical relation *distance* between every two points The theory involves considerable difficulties, and theorems which are true in one kind of distance geometry are not necessarily true in another To the thorough going pure mathematician, such studies need no justification by reference to anything outside them, but to those of weaker faith it may be comforting to notice that the abstract theory can be applied to determinants, curves and surfaces, and the calculus of variations There is, at present, no mention of any application to physics However, in these days, when new attempts to bring physics under the domination of geometry are liable to be made at any time, the physicist must not be surprised if he is suddenly confronted with an alarming horde of such new geometries, armed with mysterious terms and terrifying symbols

Messrs H H Lester, R L Sandford and N L Mochel, at the request of the American Society for Testing Materials jointly undertook to write an account of non destructive testing as practised in the United States Radiographic methods are widely used in the States Pressure vessel manufacturers use fifty seven installations, and there are thirty one installations for various other applications The American Society of Mechanical Engineers has greatly helped boiler makers by constructing the A S M E Boiler Construction Code of definite standards of soundness to which manufacturers have to build Porosity conditions are defined by pictures Rejectable defects such as cracks and unfused regions are specifically designated and limits of toleration are established for slag inclusions In the paper emphasis has been given to practical applications and to technological research of direct bearing on industrial practice In conclusion methods and regulations for testing porcelain and glass are given All high voltage porcelain parts designed for service above 6 6 kilovolts are given a routine flash over test In addition routine mechanical tests are made on all suspension insulators The Polaroid Corporation has recently developed a glass strain detector built for the routine inspection of glass articles during the process of manufacture

---

Rothamsted Experimental Station

THE Rothamsted Report for 1937* contains the results of experiments carried out at that Station during the year, and of crop trials undertaken at Woburn and at a number of commercial farms, extending over a large area Short accounts of the work of some of the departments of the Station are included and also an extended summary of the research carried out in the Plant Pathology Department since its formation twenty years ago

The experiments with chalk, discussed in this report, are of great interest because of the Government subsidy for the use of various forms of lime Although liming is such an old practice and although a large number of field trials have been carried out on the subject there is a lack of precise knowledge on many aspects of the problem Thus it is often said that magnesium limestones are detrimental but experiments planned at Rothamsted and carried out in various parts of Britain have given no evidence of this The residual value of chalk has also been investigated and distinct improvements were obvious in crops some years after application on an acid sandy soil for example there is little sign of the effect of the dressing of lime disappearing after six seasons of cropping

In a country with large numbers of live stock, as in Great Britain the conservation and utilization of farmyard manure is an important consideration and many aspects of these problems have been under investigation at Rothamsted from its early days In the 1937 report, the results of the early trials, which started in 1852, are dealt with briefly as a preliminary to the consideration of the more modern work The earlier, long period experiments showed that farmyard manure could give yields as high as those given by the best combination of artificial manures, and that it had considerable cumulative effects , in one instance, the increases in yield were considerable sixty five years after the last application of dung A number of modern, replicated experiments show that the response in potatoes averaged 2 1 tons per acre, and, in sugar beet, 1 3 tons per acre at Rothamsted The increase resulting from 10 tons of farmyard manure was about equivalent to that from 2 cwt of sulphate of ammonia Experiments were also carried out to investigate the effects on the yields of potatoes and of sugar beet, of different methods and times of application of farmyard manure With both crops, late application was superior to the earlier dressing With potatoes the application of the manure in the rows at planting time in the spring, gave an increase of between one and two tons per acre more than when it was ploughed in in autumn Finally, a number of experiments were undertaken to find whether artificials may be profitably applied on land that is also being dunged The responses to sulphate of ammonia were increased in the presence of dung while, with sulphate of potash there was a small decrease

An important aspect of the organized schemes of manuring experiments consists in the accumulation by the Chemistry Department of data which may make it possible to predict the fertilizer requirements of soils from their chemical analyses and textures In 1936 and 1937 sugar beet gave much larger responses than in the three preceding dry seasons and there was an opportunity of testing laboratory methods in this respect The amount of inorganic nitrogen, obtained in the soil after incubation, gave a good degree of correlation with responses to sulphate of ammonia, while, with phosphoric acid the fraction soluble in acetic acid corresponded to responses from superphosphate It is unnecessary to emphasize the importance of this line of work at Rothamsted, as it will not only assist the individual agricultural adviser, but will also greatly increase the amount of useful information that can be obtained from soil surveys

A note of this brevity cannot do more than mention the work of the Plant Pathology Department summarized in this report Among the important contributions from this laboratory must be cited the discovery of the green wart' method of infecting potatoes with wart disease , this enables susceptibility or immunity to be determined within as many weeks as had hitherto required years The investigations in this laboratory into the fundamental nature of virus diseases were extended after the Imperial Agricultural Conference of 1927, and the problem of the ultimate nature of these diseases is tackled from many angles In one study, for example, it has been found possible to arrive at estimates of the size of certain of the plant viruses. The relationship between the insect carrier and the virus is also under investigation, and some striking results have been obtained already in regard to the connexion between degree of infection, season and length of feeding times on the infected plant.

---

* Rothamsted Experimental Station Lawes Agricultural Trust Report for 1937 Pp 225 (Harpenden Rothamsted Experimental Station 1937) 2s 6d

In addition to discussions of the various investigations in progress, the report contains a wealth of other material, such as the farm report, also notes on the insect pests and fungus diseases at Rothamsted and Woburn. Many branches of agricultural science gain from the information given in this report; the close connexion between laboratory and farm, together with the carefully planned field trials, give a high value to all the data supplied.

Precision Methods of Measuring Stellar Radiation

IN a communication dated October 17, from the Smithsonian Institution, Washington, an account is given of experiments made by Dr Charles G Abbot, secretary of the Institution and Mr W H Hoover, of the Smithsonian staff, at the Mount Wilson Observatory of the Carnegie Institution at Washington, on the total energy radiated by distant stars in narrow wave length bands. For the measurement of electric current they used a galvanometer which was twenty times as sensitive as any instrument of this sort used in the past. A magnetic shield for this very sensitive galvanometer was made for the Institution by the late Dr Elihu Thomson, of the General Electric Company, one of the world's foremost inventors of electrical devices. The galvanometer itself was made at the Institution and will detect a current variation of $1/10^{13}$ of an ampere.

The galvanometer is attached to a thermocouple, the standard astronomical instrument for measuring extremely minute amounts of heat energy. The thermocouple used by Dr Abbot and Mr Hoover is a more sensitive, and at the same time a more robust instrument, than any hitherto used.

The efficiency of the new devices has just been tested in California, using the Carnegie Institution's 100 inch telescope, with encouraging results. Dr Abbot and Mr Hoover measured with a high degree of precision the relative energies in narrow bands of the spectra of a number of the brighter stars. The total heat which reaches the earth from all the thousands of millions of stars of the Milky Way is extremely small. If the earth depended on this heat alone, the temperature would be approximately −270° C. Many individual stars in the galaxy are many times hotter than the sun, but their radiation is soon dissipated in the immensity of space.

Astronomers have had for many years instruments sufficiently delicate to measure the total radiation of several of the planets of the solar system. It has also been possible within the past few years to measure the total radiation of selected single stars. The aggregate light of such a star is focused on the thermocouple, essentially a junction of two wires made of different kinds of metal, through which an electric current is caused to flow by the minute rise of temperature produced by the stellar radiation; any variation in the temperature of the junction produces an alteration in the current measured by the galvanometer. The amount of the radiation energy necessary to produce a change in the current, the distance of the star and the rate of dissipation of stellar radiation in space being known, it is possible to calculate the actual heat from the star itself.

Dr Abbot and Mr Hoover have gone a step farther. In the radiation of almost every star are to be found all the elements of the spectrum from the infra red to the ultra violet. Actually the proportions of infra red, visible light and ultra violet differ enormously in the radiation of different classes of stars. It was the problem of measuring the approximate amount of radiation from a star in different narrow bands of wave lengths that the Smithsonian astronomers set themselves. This task required the most precise measurements ever attempted.

Experience for the task was drawn from two sources. A division of the Institution has been engaged for years in measuring the precise effects on plants of illumination from different wave lengths of light. This required further development of an instrument known as the Christiansen filter to segregate narrow bands of wave lengths from the light and heat of an arc lamp and also of improvement of the thermocouple. There seems little connexion between oat seedlings growing in boxes and giant stars a 1000 light years away, but all Nature seems tied together so inextricably that the development of this technique connects the one inextricably with the other. The other source was the work of the Smithsonian Institution's observatories set up on distant mountain tops in various parts of the world, the work of which is to make very precise measurements daily of minute variations in the radiation of the sun. This has called for more and more responsive heat measuring instruments.

Dr Abbot began the present work in 1923 using an instrument called the radiometer prepared for him by the late Dr L F Nichols. In 1928 he returned to the task using a fly vane radiometer of his own construction in which the sensitive element was a small piece cut from the wing of a house fly. He has hoped to continue the experiments ever since with instrumental improvements giving greater sensitiveness. A point has now been reached where the measurement of the energy in narrow stellar wave bands can be made with high accuracy.

It is possible, however, that much greater responsiveness will be attained within the next two years before the 200 inch telescope, with which it is planned to carry out the main programme of measurements, is set up at Mount Palomar in California. It may be possible to improve the thermocouple, to eliminate the element of drift due to the sensitivity of the two joined elements.

The last measurements made by Dr Abbot were at Mount Wilson ten years ago. At that time the greatest swing of the recording light spot that could be attained was only about one millimetre. This year

Mr Hoover easily obtained swings of twenty millimetres, which is equivalent to a twentyfold preciseness in his measurements.

Far reaching results may be attained with the new technique. A means is now at hand of determining with considerable accuracy temperatures depths and compositions of the atmospheres of stars and this will make possible more accurate estimates of the size and nature of stellar bodies.

Economics of Industry

ARISING out of the Conference held in 1937 by the International Industrial Relations Institute, when the theme was productivity and standards of living as influenced by industrial relations, the Institute has arranged a series of publications, the I R I Social Economic Series, to present the results of its studies. Two of these have now appeared, the first by A Carrillo on *Mexico's Resources for Livelihood* including a general introduction to the series on the world's natural resources and standards of living (Mexico's Resources for Livelihood: a Study of the Influence of Foreign Ownership. By Alejandro Carrillo. Pp 34. The Hague and New York: International Industrial Relations Inst, 1938. 25 cents).

This introduction outlines the field opened up including an analysis of the distribution of the world's raw materials and a survey of the hitherto abortive efforts to deal with the problem through international action. The implications of power production for economic organization are also considered, and in addition to summaries of the main arguments in the papers submitted to the 1937 Conference a number of suggestions for immediate action are outlined. Mr Carrillo's special study gains further interest in view of the expropriation of oil by the Mexican Government since the paper was written and it facilitates appreciation of the situation in Mexico and the important moral achievements of the revolution.

The second paper by M Yergan on gold and poverty in South Africa, is a study of economic organization and standards of living, it is yet another indictment of the labour policy pursued in South Africa with its deliberate exploitation of native labour as part of the natural resources of the country (Gold and Poverty in South Africa: a Study of Economic Organisation and Standards of Living. By Max Yergan. Pp 24. The Hague and New York: International Industrial Relations Inst, 1938. 15 cents). The importance of workers' living standards as an element in the problem of raw materials is again emphasized, and while the report recognizes that the errors and dangers of the policy hitherto pursued are now perceived by an increasing body of European opinion, the material it presents overthrows a conception of trusteeship under the conditions which prevail in South Africa. The importance of encouraging and co-operating with all those in South Africa, whether African or European, who are aware of the dangers and real needs, and striving to meet them, is emphasized, as well as the need for strenuous efforts to eradicate the hates and prejudices which repression and exploitation have developed within the ranks of both Africans and Europeans.

Science News a Century Ago

Temperature of the Crust of the Earth

WITH the assistance of the British Association J D Forbes in 1837–38 made determinations of the temperature of the soil in the neighbourhood of Edinburgh, the results of his experiments being given in a paper read to the Royal Society of Edinburgh on December 3, 1838, entitled Discussion of One Year's Observations of Thermometers sunk to different Depths in different localities in the Neighbourhood of Edinburgh.

The principal purpose of the experiments undertaken by Forbes was to ascertain the progress of solar heat in the crust of the earth, and had no immediate reference to the question of central heat. With the view of rendering the observations comparable with those at Paris and Brussels the lowest thermometers had their bulbs 24 French feet (25 6 English) below the surface. Other thermometers were placed at depths of 12, 6 and 3 French feet. The observations were begun in February 1837 and were continued weekly.

The three stations for the experiments were at the Observatory, Calton Hill, in the sand in the Experimental Garden and in the compact coal formation sandstone of Craigleith Quarry. Among other results obtained Forbes found that at the greatest depths the annual range temperature was 1 45 F at the Observatory, 2 1 F at the Garden and 4 1 F at the Quarry.

Footprints of the *Chirotherium*

AT a meeting of the Geological Society on December 1838, one of the communications was An Account of the Footsteps of the *Chirotherium* and five or six other unknown animals lately discovered in the quarries of Storeton Hill between the Mersey and the Dee. The communication was made by the Natural History Society of Liverpool and was accompanied by drawings by J Cunningham. In 1834 there were discovered in several quarries at the village of Hessburg near Hildberghausen casts in a grey quartzose sandstone, resembling to some extent a human hand, and for which Prof J J Kaup proposed the provisional name of *Chirotherium*. In June 1838, similar casts were discovered in the Storeton Hill quarries. The Natural History Society of Liverpool appointed a committee to report on those.

The red sandstone of the peninsula of Wirral may be divided into three layers: a lower consisting of a red or variegated sandstone and conglomerate, a middle of white and yellow sandstone, and an upper or red or variegated marl and sandstone containing pebbles of quartz. It is the middle division which was worked at the quarry. The strata there are of unequal thickness, and are separated by thin seams of whitish clay. The casts appear to have been moulded in impressions made by the *Chirotherium* and other animals walking over the clay.

The animal had been tracked by its marks 16 ft on one stone. Although the footsteps of the *Chirotherium* are the most prominent there are slabs covered by raised casts apparently made by tortoises and saurian reptiles.

The Victoria History of the Counties of England

WHEN in the early months of the present year the one hundredth volume* of the Victoria History of the Counties of England issued from the press it marked a memorable achievement in which all who have been associated with the work may feel a legitimate pride Inevitably this feeling is mingled with regret that so many among the promoters and the collaborators of earlier days cannot now enjoy the credit that is their due not least among them the one man the late Dr William Page to whose courage tenacity of purpose and organizing ability we owe it that this great undertaking is still in existence to pursue its way towards completion

The Victoria History of the Counties of England was conceived on a generous scale and when the original promoters came to work out their plan in detail the magnitude of the task they had undertaken might well have daunted the boldest Something of its stupendous character the organization involved and the difficulties to be overcome of which not the least has been finance may be gauged from the fact that in just under forty years less than one half of the work has been completed

The conception of a new history and survey of the counties of England to supersede the partial out of date and often unsatisfactory records existing in the closing years of the last century was due to Mr (afterwards Sir) Laurence Gomme whose genius as a research worker in the remoter fields of the social history of the English people was equalled only by his vision in the co ordination of learning in the study of the past and his power of inspiring others with an enthusiasm like his own The survey was planned to cover the natural features the geology natural history the archaeology and social history in the broadest sense of each county But its essential feature and as it were its mainspring was to be the topographical record a detailed descriptive and historical account of town village and hamlet not only including important historic buildings but also omitting no feature of historic antiquarian or architectural interest For example the record covers those important factors in the development of English social life the manors tracing their history in the various families that have held them not omitting to give consideration to the heraldry of these as well as of the other important families of the county The most casual glance through the pages of the hundredth volume covering the topography of a division of Sussex will serve to indicate how faithfully and with what competent completeness the original scheme in this department of the work has been respected and carried out Not only has care been lavished on preparation to ensure accuracy of detail but also every effort has been made to ensure that no least item of interest or significance should escape notice Needless to say county records have been ransacked for rare and usually inaccessible documents plans maps and illustrative material which might serve to illuminate past history The scale of the work and the labour involved in its preparation may be estimated from the fact that the record of no county will be completed in less than three volumes several run to nine while one Norfolk will require ten volumes One volume is to be given to Roman England

---

* The Victoria History of the County of Sussex Edited by L F Salzman Vol 9 The Rape of Hastings (The Victoria History of the Counties of England) Pp xv + 279 + 63 plates (London Oxford University Press 1937) 42s net

It is of interest to note the origin of the title of the History When permission was sought to dedicate the project of providing a history of every county of England to Her Majesty Queen Victoria its importance was at once recognized by her Not only did she graciously accept the dedication but she also commanded that the history should bear her name A like patronage has been extended to the work by her successors Each in turn has expressed sympathetic interest in its progress and on the occasion of the celebration of the publication of the one hundredth volume Lord Athlone as Chancellor of the University of London read the following message from H M the King

> The King has learned with much satisfaction of the publication of the hundredth volume of the Victoria County History which you are celebrating His Majesty cordially congratulates all concerned in this notable achievement and desires to assure you that he fully shares the interest evinced by his predecessors in the progress of the work

The scheme for this boldly conceived county survey was successfully launched by the publication of the first volume of Hampshire in 1900 Mr H A Doubleday being the editor Two years later Mr W Page was joined with him and in 1904 became sole editor continuing to act in that capacity until his death in 1934 This long period of office was one of many vicissitudes and anxieties In the first four years of his editorship between 1904 and 1908 Mr Page accomplished the remarkable feat of publishing no fewer than thirty nine volumes of the History to which professional and lay workers extended a cordial welcome for its accuracy scholarship and technique of production At this point however financial difficulties began to press and the rate of publication slackened until with the outbreak of war in 1914 the work came to a standstill

At the close of hostilities the position of the History offered little prospect for the future The efficient staff which Mr Page had collected and trained had been dispersed and the affairs of the History lay in Chancery until the late Lord Hambleden came to the rescue purchasing all assets and rights which he handed over to the editor in 1922 Nothing daunted by the difficulties which confronted him Mr Page set to work, and in the next ten years published eighteen volumes relying for his financial resources on what could be raised for the production of each volume in turn In 1932, however feeling the burden of his years and anxious to secure the continuance of the work he offered the History to the University of London The gift was accepted and since then publication has been carried on by the University the work of administration being entrusted to the Institute of Historical Research

Although the continued existence of the History is assured by its transfer to the University of London it by no means follows that all difficulties standing in the way of that steady and rapid progress towards completion which is essential to its value as a record have been smoothed away As chairman of the University Court Lord Macmillan pointed out on the occasion of the celebration to which reference has already been made while the University holds itself responsible for general expenses including a too exiguous staff it is not in a position to bear the burden of payments to contributors and costs of production which up to the present have exceeded the income from sales by on the average a sum of £700 for each volume At present the University does not feel justified in commissioning a new volume until it is assured that such a sum will be made good by public and private benefaction It is however to some extent reassuring to note that at the time this statement was made the authorities had put in hand the preparation of seven new volumes For these volumes adequate financial assistance has been secured but continued publication depends upon further support

For a work of the character and scope of the Victoria County History it is obvious that the ordinary channels are of little avail No doubt as the value of the work is more widely recognized larger sums will accrue from its sale The present tendency towards an increased interest in local antiquities and history among the public justifies such an assumption and the appearance of the County History on the reference shelves of public libraries in the more important centres of population will be expected as a matter of course Nor doubtless will the private benefactor ever be entirely lacking But it cannot be anticipated that these sources will be adequate to meet the needs of publication without substantial backing from the public purse That a more liberal flow of funds from this source is to be anticipated is indicated by recent action of the Minister of Health He has announced his willingness to sanction application from local governments for leave to make grants for the completion of histories of areas within their jurisdiction Substantial help under the provisions of this announcement has already been received from several local government bodies including the County Council of Warwickshire and the City Councils of Birmingham, Coventry and Oxford. This example might and no doubt will be followed liberally by other local councils in due course.

There are, however, a number of reasons for urging that a publication doing work such as that which the County History might carry out, given a more rapid rate of publication, is of national and not merely of local interest, and should be subsidized from national funds, just as in the instance of an ancient monument it has not infrequently occurred that its importance as a piece of historic evidence of national interest has justified a nation-wide appeal for funds for its preservation. There can be no two opinions that it was a calamity that publication of the Victoria County History had not been completed before the outbreak of hostilities in 1914. If the contemplated county survey had been complete then, it would present a unique summation of the development of English culture at a time when, had we but known, it was about to suffer a fundamental transformation. Although we have it now but in part, it is no less important that we should have as its pendant a record at the present time when the character of the English countryside is changing before our eyes. Time is the essence of the contract, and it is desirable in the extreme that the record should be made before these changes have gone too far on their way. No doubt local interest in the long run will ensure that in due course each county history will attain completion; but as a national undertaking—and the Victoria History as a whole is no less—the value of the survey resides to a great degree in the extent to which it can present a series of contemporary pictures giving in sum a record of the cultural development of England as a whole. This is a work of educational value to the entire nation both now and future generations, and as such is one which national resources might be asked to subsidize apart from the contribution of local funds. It is true that it may be urged that in respect of evidence of antiquity still standing the obligation of national funds is met by the work of the Historical Monuments Commission. However valuable the work of that Commission may be as a record, it cannot give the facts their natural and cultural setting. It is this setting which eventually, when the Victoria County History is complete, will endow it with abiding value.

The Botanical Gardens, Leyden

1587–1937 Hortus Academicus Lugduno Batavus: The Development of the Gardens of Leyden University. By H. Veendorp and L. G. M. Baas Becking. Pp. 218. (Haarlem: Typographia Enschedaiana, 1938.)

A CERTAIN amount of confusion exists in the minds of some botanists concerning botanical gardens, especially with reference to their origin and history. This is probably due in no small measure to a misunderstanding of the term. Botanical gardens may be considered to be gardens in which the plants are deliberately arranged according to botanical classification and where plants are grown and studied from the point of view of their botanical and economic importance. In this way such a garden differs widely from a park. The former has as its primary objective botanical research and education; the latter that of beauty and recreation. The fact that the objectives in nearly all cases overlap is immaterial.

Failure to recognize the distinction between a botanical garden and a park probably explains the difference of opinion concerning the Vatican Gardens. Some claim that these gardens are the oldest existing botanical gardens in the world, since they were established by Pope Nicolas III in 1277. Since that date their location has been changed several times, the present-day Gardens being founded in 1883 at the foot of Janiculus. They are twenty-seven acres in extent. Botanists who claim these Gardens as the oldest botanical gardens do so on the grounds that a small portion of them was used for pharmaceutical and experimental purposes. Others point out that the Gardens were founded by Nicolas essentially as a recreative park. Thus the experimental side was merely a side issue.

One of the first botanical gardens of which there are authentic records was the Royal Garden founded by Thothmes III at Karnak in Egypt more than three thousand years ago. The plants cultivated there were probably of utilitarian value. Another early garden established with the express purpose of aiding the study of plant life was that founded by Aristotle in the fourth century B.C.

and placed under the direction of his pupil, Theophrastus.

The immediate precursors of the present-day botanical gardens of the world were the physic gardens of the monasteries and convents. Their contents were determined chiefly by therapeutic and culinary value. Herb-lore was the prerogative of the layman, but the more systematic study and cultivation of plants of proved medicinal value remained with the cloister gardens.

Later, plant drugs and even living plants began to seep into Europe from the Near East, and in the early sixteenth century the science of pharmacognosy became established in Pisa (1543), and Padua (1545), where medicinal gardens attached to the Universities were established. The founder of the Pisa garden was Prof. L. Ghini, but the gardens achieved greater fame under their second director, Andrea Cæsalpini, whose work marked the beginnings of present-day systematic botany. In Italy, other botanical gardens followed Padua, among the best-known of which were Florence (1556), Bologna (1657) and Rome (1660).

The Jardin Royal des Plantes Medicinales was founded in Paris by Guy de la Brosse, the king's physician in 1635. Its present name, Musee d'Histoire Naturelle, was given to it in 1790.

The Chelsea Physic Garden was established in London by the Society of Apothecaries in 1673. It was established for the study and teaching of botany and for providing material to that end, and was extended by Sir Hans Sloane in 1722. It was handed over to a committee of management for botanical research in 1902.

Schöneberg, near Berlin, was the scene of the foundation of the Staatliche Botanische Garten und Museum in 1679; but during 1897–1907 the garden was transferred to its present site in Berlin-Dahlem. It is now about 100 acres in extent.

The world-famous Royal Botanic Gardens at Kew, Surrey, of an area of 288 acres, are a much younger institution. Plants grown by Lord Capel of Kew House formed the nucleus of the Gardens, and in 1757, William Aiton, a former student in the Chelsea Physic Garden, was appointed to extend this nucleus also as a physic garden. But the Gardens were not established as a national garden until 1841, under the direction of Sir William Hooker.

Last year, the Botanical Gardens of the University of Leyden celebrated their three hundred and fiftieth anniversary, which is of special interest since Dutch botanists and Dutch botanical gardens have had an exceptionally important role in the development of botanical science throughout the centuries. The names of Leeuwenhoek, Swammerdam, Ingenhousz, van Marum and Hugo de Vries are sufficient to establish claim to pre-eminence in this field. Furthermore, apart from the Gardens at Leyden, there are several others of first importance, such as those at Amsterdam, where de Vries carried out his epoch-making genetical experiments on *Œnothera*. Furthermore, the wonderful collections in the Gardens at Buitenzorg in the Dutch East Indies are known to all present-day botanists. These Gardens were founded by C. G. C. Reinwardt, who was director of the Leyden Gardens in the early eighteenth century.

Even to-day, botanists are much indebted to Holland, and especially Amsterdam, The Hague and Leyden, for the advancement of their science. Botanical research is very healthy in that country; its present botanical publications include *Chronica Botanica*, under the editorship of Dr. Verdoorn, which is international in its scope, and many other journals and also books of more specialized interest. Now comes the commemoration volume of the Botanical Gardens at Leyden, which is of interest not to botanists alone but also to other men of science.

The University of Leyden was founded in a monastery in 1575, but owing to lack of space the establishment of a medicinal garden was deferred. Later, the municipal council granted an extension of land and the Gardens were established in 1587. The professor of medicine, Geraerdt de Bont, was offered an increase in salary of fifty guilders "if willing to continue as well in winter time to explain and administer anatomy, as in summer to explain the herbs to students of medicine".

In 1589, de Bont was succeeded by Pieter Pauw as professor extraordinarius of medicine. Owing to internal dissension, however, little was done for the Gardens, and in 1592, Clusius (Charles de l'Escluse) was appointed. It was Clusius who foresaw the great importance of plant bulbs.

The first inventory and plan of the Gardens were made in 1594. The Gardens were divided into four quadrangles by intersecting paths and contained more than a thousand different species. Though no particularly systematic plan was followed at that time, the "Index" of 1594 was that of a *hortus botanicus* rather than a *hortus medicus*, showing that the Gardens were an expression of Clusius's purely botanical point of view.

The first printed catalogue of the Gardens appeared in 1601. In 1685, there were three thousand species in the Gardens; in 1740, seven thousand; and at the present time there are between eight and nine thousand.

The 1628 catalogue owed its existence to the fact that the then director, Adolf de Vorst, was asked to show "more activity and application". The catalogue of 1633 showed the appearance of several North American species, the centre of distribution of which was Paris. It is characteristic that the most common specific name applied to these plants by the French was *canadensis*, by the British, *virginicus*, and by the Italians, *indicus* Among other introductions were the Virginian creeper and the Jerusalem artichoke

Herman Boerhaave was appointed director of the Gardens in 1709 He has been described as "a Physician and plant-lover by the Grace of God, Professor of Chemistry and of Botany by the Grace of the Board of Curatores" Among his botanical correspondents were William Sherard and Hans Sloane It is interesting to note that when considering his successor in 1729, Boerhaave had in mind Scheuchzer of Zurich and Dillenius of Oxford, but since neither was a chemist both were rejected, and A van Royen was appointed

Linnæus visited the Botanical Gardens at Leyden for the first time in 1735 He formed a close connexion with the Gardens, and dedicated his "Genera Plantarum" to Boerhaave, who wrote of the work, "centuries shall praise it, the good will follow it, all will derive profit from it" The human element comes in when we read that in order to coax Linnæus, Boerhaave offered him a two-year plant-collecting trip to the Cape, but Linnæus declined it since he had a bride waiting for him in Sweden

With a further succession of directors, the Gardens continued in prosperity, and many more species, especially of Japanese origin, were acquired In 1891, Jacobus Janse was appointed to the chair, where he did forty years of splendid work He retired in 1930 and has only recently died

The Gardens are now under the directorship of Prof L G M Baas Becking, co-author of the work under review His is a splendid heritage In the Gardens of to-day, periods of architecture and centuries of endeavour are reflected But there is no fear for the future of the Gardens They are in good hands, as reflected in Prof Baas Becking's concluding words in this monumental book 'We have cause to be contented, *but we should take care lest we be satisfied*'

The authors of this book, H Veendorp, *hortulanus*, and L G M Baas Becking, *praefectus horti*, are to be congratulated on a work of inestimable value to botanists, for apart from an absorbing history of one of the most important of botanical gardens, we are offered a wealth of botanical information of more general appeal

The text is beautifully illustrated with sketches by J Spier, D A Bueno de Mesquita, J Raphael and Miss M L E van Weydom Claterbos

Data of Ferromagnetism

Magnetische und elektrische Eigenschaften des Eisens und seiner Legierungen

Von Dr O v. Auwers (Aus "Gmelins Handbuch der anorganischen Chemie", herausgegeben von der Deutschen Chemischen Gesellschaft) Pp lxii + 1421–1634 +466 +148 (Berlin Verlag Chemie, G m b H , 1938) 84 gold marks

TWO parts of "Gmelins Handbuch" dealing with the magnetic and electric properties of iron and its alloys have previously been published, the first dealing with 'pure' iron and the iron-carbon system (1934), and the second with alloy steels (1936) These are brought together in the present volume, with a supplement covering the literature up to September, 1937

Magnetic and electric properties are surveyed in separate sections in each part, the magnetic sections accounting for about three quarters of the whole The first part opens with an introductory section dealing with definitions and units, and in a general way with theories of ferromagnetic phenomena Most of the experimental material is presented under the main headings of intensity, susceptibility, and hysteresis The effects of form grain size, thermal and mechanical treatments, temperature, strain, and alternating fields are reviewed under each heading Further sections deal with the Barkhausen effect, magnetostriction, and galvanomagnetic effects The survey of electric properties includes sections on resistance, contact potentials, and thermo electric effects In the second part, some six hundred alloy systems are treated in turn in the Gmelin system order at a length ranging from that of a treatise, as for the magnetic properties of the iron-silicon and iron-nickel systems, to that of a bare reference

Apart from a number of general literature lists, the references are incorporated in the text, to the number of tens of thousands The text is largely a guide to the literature, either without comment, or with brief abstracts, supplemented by general surveys introducing many of the sections In spite of the necessity for conformity with a rather rigid plan, the author of the text has succeeded remarkably well in infusing a measure of spontaneity into the presentation, and a profound familiarity with the subject-matter is shown by the easy conciseness and clearness, and by the appositeness of cross-reference and footnote

Extensive numerical data and numerous diagrams are given these forming one of the most valuable features of the work

With the general scheme of arrangement of the Handbuch based on the subdivision of subject matter by substances reference to the work done on any particular alloy is very straightforward Reference for other purposes is facilitated by summaries at the ends of the second and third parts indicating under which alloys the more important phenomena are discussed and by extensive tables in which the alloys are arranged in accordance with their properties There are also lists of patented alloys similarly arranged and of the compositions of alloys having special trade names

It is for the unprecedented comprehensiveness of the survey of ferromagnetic properties that this volume is particularly valuable As a treatise on ferromagnetism it inevitably suffers from the fact that nickel and cobalt cannot be considered except as constituents of alloys and that the theoretical side can be considered only incidentally As a record of experimental data and as a guide to the literature however it is in a class by itself It will be invaluable not only to chemists but also to physicists concerned with magnetism to metallurgists and to electrotechnologists

Examination of this volume focuses attention on the overwhelming mass of experimental work which has been carried out on ferromagnetism against which understanding of ferromagnetic phenomena is revealed as still pitifully meagre It is difficult to avoid the feeling that if even a small fraction of the energy devoted to the accumulation of experimental data had been diverted to serious theoretical investigation a much more satisfying state would have been reached not only in the science of magnetism but also in the associated practical art

Castelnuovo's Collected Works

Memorie scelte
Per Guido Castelnuovo Pp x + 588 (Bologna Nicola Zanichelli 1937) 125 lire

PROF CASTELNUOVO'S scientific jubilee occurred in the year 1935 and in the same year he retired from the professorship of geometry at the University of Rome a post which he had held for nearly forty five years To mark the occasion his friends and pupils urged him to publish a book of memoirs and decided to found in his name a scholarship at the University to which the proceeds from the sale of the book should be devoted After some delay the book has now appeared Containing as it does most of Castelnuovo's major works it needs no introduction to students of algebraic geometry who at one time or another find it necessary to consult all of them Its value is enhanced by the fact that here and there the author has added brief commentaries of great interest showing the relations between the various papers and giving some account of their inception

The present book opens with a series of papers representative of the author's work during the early Turin period (1887–91) when he was in daily contact with Corrado Segre It has been said that the modern geometry of curves was born under the arcades of Via Po Turin the fruit of conversations between the two young mathematicians In proof of this the second paper of the series contains the celebrated result concerning the maximum genus of a curve in a given space These researches culminate in a long memoir on plane curves which may be said to initiate the modern study of linear systems from the invariantive point of view To Castelnuovo we owe the introduction of those *virtual* characters which play a leading part in all later developments

The second period which begins with Castelnuovo's appointment to the chair of geometry at Rome is remarkable for the wealth of results and for the unity of aim displayed throughout The years 1892 97 saw the creation in the theory of algebraic surfaces of a vast new branch of geometry which is almost entirely the work of two men Castelnuovo and Enriques Castelnuovo's own contribution to it was a long chain of memoirs which dispose of an array of important problems many of them landmarks in the theory The whole of this work is characterized by the utmost originality and resourcefulness the author has had to forge his own technique for each special problem

First comes a number of preparatory notes which discuss various simple types of rational surfaces and criteria of rationality These it now appears were almost prophetic for they were destined to be invaluable in the general discussion which almost always reduces in the last analysis to the examination of particular cases Then follows a group of famous memoirs on the rationality of plane involutions, the conditions of rationality of a surface and an exhaustive study of linear systems of curves on a surface, with all the remarkable inferences which can be drawn from it So intense was this period of research that few fundamental questions remained to be settled afterwards One of them however was disposed of only a year ago by Beniamino Segre

In the ensuing period the author's interest turns from the methods of algebraic geometry proper to the consideration of transcendental questions The most celebrated paper of this group contains the theorem that the number of simple everywhere finite integrals attached to an algebraic surface is equal to the so called irregularity of the surface This third series concludes with some interesting researches on Abelian functions The final paper is devoted to a very different topic—the statistical problem of moments

To anyone with a knowledge of Italian though not necessarily of geometry these papers will have an extra mathematical interest they are written in a style which for sheer lucidity and directness has never been surpassed Castelnuovo has that rare capacity for going straight to the heart of a difficult problem of seeing where the difficulty lies and resolving it in successive stages all apparently of the utmost simplicity Altogether this book is the most fitting memorial to the great period of Italian mathematics which now it seems is drawing to a close

Laboratory Experiments in Biochemistry

Fundamentals of Biochemistry, with Laboratory Experiments
By Prof Carl L A Schmidt and Dr Frank Worthington Allen (International Chemical Series) Pp xv + 388 (New York and London McGraw Hill Book Co Inc 1938) 18s

THIS is a book for the beginner in America It starts with a definition of the purpose of laboratory training which every old stager in science will applaud The incalculable gift of the laboratory is its discipline in scientific method and its training in the importance of logical reasoning and the use of exact language in speaking and in writing The student is enjoined to supply himself with a laboratory coat a box of matches a set of weights a note book and a slide rule So equipped the scientific world lies open before him

The standard of biochemistry and chemical physiology is so high in the United States to day that one may justly infer that the subject is being well taught, particularly in the laboratory The object of the special experiments here described is defined as "to teach the student the sources of the facts of biochemistry to integrate information to carry out a well controlled experiment and to present the facts in a co ordinated and logical manner".

There is no doubt that the object is the same in Great Britain also but any time when half a dozen employers are gathered together they will tell you that the normal product of the British university definitely fails to meet such criteria The question may justifiably be asked whether our present training is not too theoretical ? As has been aptly written by Dr S Miall We should not regard the young as carboys into which you can put pints or litres of knowledge For the moment the fight against examinations as the one test of education appears lost or in abeyance there are but few reformers left to combat in this field The fact remains however that in many respects the Americans are better trained more practical to day than British graduates it is evidenced by the way the United States is going ahead in scientific work and what is more important in its practical application

It is opportune to sound this warning note and to express the hope that teachers in Great Britain will examine with care books such as this one so that they may ascertain the differences between British and American methods

This is not the place for its detailed examination there is no novelty in the experiments or in the facts presented in its text which is crisp and contains a great deal of information in a small compass Its perusal leaves us with the feeling rightly or wrongly that it would inspire a young man to dig further into the subject and try to keep abreast of its progress The essential facts are clearly presented whether the substance is simple or complex in structure

> Further deeper may you read,
> Have you sight for things afield '

says Meredith Surely it is in this spirit that the training of men whose work takes them near to Nature should be conducted

E F A

(1) Experimental Cookery:

from the Chemical and Physical Standpoint, with a Laboratory Outline By Prof Belle Lowe Second edition Pp xi+600 (New York John Wiley and Sons, Inc, London Chapman and Hall Ltd, 1937) 22*s* 6*d* net

(2) Food Technology

By Dr Samuel C Prescott and Prof Bernard E Proctor Pp ix+630 (New York and London McGraw Hill Book Co, Inc 1937) 30*s*

(1) THE object of this book is to present the knowledge of food preparation and cookery processes from a chemical and physical point of view, particularly from that of colloid chemistry A citation from Ostwald is appropriate Much as every one would like to obtain better food for less money the study of such questions is regarded as menial and best left to the cook A scientific study of the preparation of food is considered as only amusing in scientific circles

The book is intended for students of home economics and for food preparation courses in colleges It is highly informative and in advance of most other books on the subject

(2) This book of American origin, is designed for students who hope to find a place in the food industries it seeks to bring into a single volume the laws and processes of biology, physics chemistry and engineering used in the preparation and preservation of food products It is certainly a mine of information brought together in a congested form but written with a light touch so as to make interesting reading

The staple foods are dealt with in turn cereals, sugar, vegetables and fruits, of plant origin, meats, dairy products and fish, of animal origin Half the book is devoted to the processes of food manufacture It may be claimed that full knowledge is available how to prepare first class foods of all types under hygienic conditions so that there is no excuse for delinquents, who should be severely dealt with It is for the public to select a proper diet in relation to their means and for the dieticians to explain why we must have fresh food also

Mœurs et histoire des Peuls

1 Origines, 2 Les Peuls de l Issa Ber et du Macina, 3 Les Peuls du Fouta Djallon Par Louis Tauxier (Bibliothèque scientifique) Pp 422+16 plates (Paris Payot et Cie 1937) 75 francs

THE Peuls, as they are known to the French authorities who have adopted the Wolof name, but more commonly known in English as the Foula or Fulani, are a pastoral people, widely scattered as a dominant caste over that part of northern Africa extending from Nigeria to Senegal and from the Atlantic to Lake Chad They were known to Arab writers of the fifteenth century, but they appear to have reached northern Nigeria as an immigrant nomad people at the end of the thirteenth century, their conquest of that country, however, dating from 1804 when the Moslems declared a Holy War against the pagan rulers In French territory their principal groups are Peuls of Fouta Toro (Ferlo), of Nioro, of Macina and Fouta Djallon, their numbers being estimated at 1,790,000, while in Nigeria there are said to be some two millions

Various theories have been put forward as to their origin, some of a fantastic character It is now generally accepted that they are of southern Hamitic origin, while their language is an archaic Hamitic tongue

M Tauxier whose opportunity of observation in the field among the Peuls extended over many years, here presents a critical survey of the information relating to them, and discusses critically the literature dealing with their origins, social organization and history, which he analyses in the light of his personal studies His work, more especially in regard to the people bordering on the Niger and of Fouta Djallon, is the most complete study which has yet been made

Analytic Geometry and Calculus

By Prof Max Morris and Prof Orley E Brown Pp x+507 (New York and London McGraw Hill Book Co Inc, 1937) 21*s*

THE authors of this volume have taken for their aim the axiom that the best preparation for the calculus is a suitable course in co ordinate geometry The text is thus divided into two sections the first, consisting of six chapters is devoted to analytic geometry, and the second to the calculus The former embraces both plane and solid geometry and deals not only with the conics but also with cycloids, exponential and logarithmic curves together with several curves of historical interest like the Cassinian Ovals The section on calculus begins with a discussion of limits, continuity and derivatives Then follows a sound exposition of integration partial differentiation, multiple and line integrals infinite series and finally a chapter on differential equations

The book abounds in exercises for the student, both of the academic drill type and of the more practical problematic kind The text is also excellently illustrated with clearly drawn diagrams Although the book is adapted to the needs of American students, it should be of much value in Great Britain

Ixodoidés

Par Prof G Senevet (Faune de France 32 Fédération française des Sociétés de Sciences naturelles Office central de Faunistique) Pp 101 (Paris Paul Lechevalier, 1937) 50 francs

THIS useful synopsis deals not only with the French species but also with those found in countries bordering on the Republic Since the various species found in Great Britain are also included, this work provides a handy and ready means for their identification In addition to the descriptions of each of the species enumerated, an account is given of its range of distribution, its hosts and its pathological relations At the end of the work a list of hosts is appended, arranged in taxonomic order, together with the various Ixodidæ known to parasitize them Prof Senevet has written a memoir which may be recommended as being well up to the high standard attained by others in the series to which it belongs

The Atmospheres of the Planets*

By Dr. H. Spencer Jones, F.R.S., Astronomer Royal

DURING the last few decades the main interests of astronomical research have shifted rapidly from the solar system outwards. Nevertheless the planets have not been entirely neglected in recent research. The great light-gathering power of large modern telescopes has enabled spectrographs of very high dispersion to be used for the more detailed study of the spectra of the planets and the great advances in the manufacture of plates sensitive to the infra-red region of the spectrum have made possible the investigation of a region of the spectrum the importance of which arises from the fact that the selective absorptions by planetary atmospheres lie mainly in this region.

From theoretical considerations it is possible to decide whether or not any planet may be expected to possess an atmosphere. The natural tendency of an atmosphere is to diffuse away into space. In order to overcome the gravitational pull of the planet any particle whether large or small must acquire a velocity greater than a certain minimum value determined by the mass and radius of the planet.

The rate at which this loss of fast-moving molecules from the upper atmosphere takes place depends upon the relative magnitudes of the velocity of escape and of the mean velocity of the molecules. Jeans found that if the velocity of escape is four times the mean molecular velocity the atmosphere would be practically completely lost in fifty thousand years but if the velocity of escape is five times the mean molecular velocity twenty-five thousand million years would be required for the loss to be almost complete. If therefore the velocity of escape is as great as five times the mean molecular velocity of hydrogen the atmosphere will be practically immune from loss.

The velocities of escape from the moon and from Mercury are not much greater than the mean molecular velocity of hydrogen so that an atmosphere of hydrogen would escape almost instantly from either body. It appears that the moon if it had never been hotter than at present would have lost water vapour nitrogen and oxygen completely, but would have retained carbon dioxide and heavier gases; Mercury, under the same supposition would have lost almost all its water vapour and nitrogen and most of its oxygen, but would have retained heavier gases to a large extent. The loss is likely to be under-estimated because during the initial rapid cooling the loss must have been considerable. It is certain that the moon has no atmosphere now. The evidence of an atmosphere on Mercury is not fully conclusive but the opinion of Antoniadi that Mercury may possess a very tenuous atmosphere is not in conflict with the theoretical evidence.

THE EARTH

Coming to the earth the escape velocity is 11·2 km./sec. which is almost exactly six times the mean molecular velocity of hydrogen at 0° C. Hence the atmosphere of the earth should be immune from loss of hydrogen and all other gases. At the present time the amounts of hydrogen and of helium in the earth's atmosphere are very small. The supply is being gradually replenished by the weathering of the igneous rocks of the earth's crust which contain uranium and thorium and also consequently helium. Yet the atmosphere does not now contain more than a fraction of the amount of helium that it has gained in geological times. There is thus direct observational evidence that helium is being lost from the atmosphere at the present time.

There is one process by which the escape of helium can be brought about. It is well known that the night sky is faintly luminous. In the spectrum of the night sky the characteristic green auroral line as well as the two red lines are always present. These lines are emitted by oxygen atoms that are in what physicists term a metastable state. The atoms in a metastable state may remain for an average time of a second or longer in that state before emitting their energy in the form of radiation. There is a high probability that before this occurs the atom will have collided with another atom when its energy will be converted into kinetic energy. By such a collision an atom of hydrogen or of helium could acquire a speed greater than the velocity of escape from the earth but an atom of nitrogen or oxygen would not by this process acquire sufficient speed to escape. The loss of hydrogen and helium from the atmosphere of the earth is thus made possible by the fact that free oxygen is present in the atmosphere.

---

* From the Norman Lockyer Lecture delivered under the auspices of the British Association on December 6.

It appears probable that the primitive earth must have remained hot sufficiently long for most of its initial atmosphere to have been lost. It was pointed out by Russell and Menzel that in the stars and the nebulæ neon is as abundant as argon, whereas in the earth's atmosphere argon is five hundred times more abundant than neon. Nitrogen is far less abundant on the earth than in the stars. These large differences in relative terrestrial and solar abundance can be accounted for on the supposition that the rate of loss of atmosphere was very rapid when the earth was hot. When the cooling had proceeded sufficiently far for the escape of the atmosphere to cease, neon had been depleted to a much greater extent than the heavier argon. If this supposition is correct, much of the original oxygen, nitrogen and water vapour and all the original helium and free hydrogen must have been lost. As the molten earth cooled, great quantities of water vapour, carbon dioxide and other gases would have been evolved from the solidifying magma; these with the residual gases from the initial atmosphere, formed the new atmosphere which as the earth was then relatively cool, could not escape.

The presence of free oxygen in the atmosphere of the earth needs explanation, for processes are in continual operation that are depleting the store. One of the principal causes of depletion is the weathering of the igneous rocks to form sedimentary deposits which is occurring. In this process much of the ferrous oxide is oxidized to ferric oxide. It has been estimated that during geological times the amount of oxygen thus depleted from the atmosphere is about twice the quantity now present. It is clear that the oxygen must be replenished in some way, and this is done by green vegetation on the earth's surface.

VENUS

The atmosphere of Venus is in marked contrast to that of the earth. The velocity of escape from Venus is 10·2 km./sec. It may therefore be expected that Venus will have an atmosphere comparable with that of the earth in extent and density. The presence of an extensive atmosphere is confirmed by observation. Photographs in ultra-violet light record cloudy markings which rapidly change their form and are of short duration.

To determine the composition of the atmosphere of Venus, or of any other planet, recourse must be had to the spectroscope. Absorption in the atmosphere of the earth is a complicating and troublesome factor. These absorptions can be identified in two ways. First, by observing the spectrum of the sun at different altitudes; the terrestrial absorptions become stronger the lower the altitude. Secondly, if the spectra of light from the east and west limbs of the sun are compared, the absorptions of solar origin show a slight relative displacement caused by the solar rotation, whilst the absorptions of terrestrial origin are undisplaced. The absorptions of terrestrial origin having been identified, the absorptions produced in the atmosphere of a planet can be investigated by photographing the spectra of the planet and the moon on the same night and at the same altitude. Any absorption present in the spectrum of the planet and not in that of the moon, or much stronger in the spectrum of the planet than in that of the moon, must originate in the atmosphere of the planet. Another, and more delicate, method of investigation is to photograph the spectrum of the planet at a time when it is approaching or receding from the earth most rapidly. The absorptions due to the planet's atmosphere are displaced with respect to those due to our own atmosphere.

Complete information about the constitution of any planetary atmosphere is not obtainable, however, because many possible constituents of the atmosphere show no absorptions in the region accessible to study. Amongst such undetectable constituents are hydrogen, nitrogen, helium, neon and argon.

The investigation of the atmosphere of Venus has given no certain evidence of the presence of oxygen. Observations have led to the conclusion that the amount of oxygen must be less than one thousandth part of that above an equal area of the earth. More surprising, perhaps, than the failure to detect oxygen, is the failure to detect the presence of water vapour, even though the tests for water vapour are less sensitive than those for oxygen.

The most interesting fact about the atmosphere of Venus is the great abundance of carbon dioxide. In 1932, Adams and Dunham discovered three well-defined bands in the infra-red region of the spectrum of Venus. These bands had not at that time been observed in any terrestrial spectrum. Theoretical investigations indicated that they might be due to carbon dioxide; this was first confirmed by Dunham. Later, Adel and Slipher reproduced the three bands by passing light through 45 metres of carbon dioxide at a pressure of 47 atmospheres; the absorptions so obtained were less intense than the corresponding absorptions in the spectrum of Venus. They concluded that the amount of carbon dioxide above the surface of

Venus is equivalent to a layer two miles in thickness at standard atmospheric pressure and temperature For comparison it may be mentioned that the amount of carbon dioxide present in the earth s atmosphere is equivalent to a thickness of only about 30 feet

The carbon dioxide will have a powerful blanketing effect and it is not improbable that the temperature at the surface of Venus may be as high as or higher than that of boiling water The high temperature the lack of oxygen and the abundance of carbon dioxide can be interpreted as indications that there cannot be any great amount of vegetation on Venus

MARS

Mars occupies a position between Mercury on one hand and Venus and the earth on the other as regards size mass and velocity of escape The velocity of escape is 5 0 km /sec It may be expected that Mars will have a much thinner atmosphere than Venus or the earth The presence of an atmosphere on Mars can be proved by photographing the planet in light of different colours Photographs in the infra red show permanent markings which are evidently surface features whereas photographs in the ultra violet show none of these The atmosphere is extensive enough to scatter ultra violet light to such an extent that the light cannot penetrate to the surface and out again The difference in size of the images in ultra violet and infra red light indicates that the atmosphere extends to a height of fully fifty miles above the surface

The polar caps provide additional evidence of an atmosphere on Mars They wax and wane with the changing of the seasons The changes are to be explained by the melting or deposition of ice snow or hoar frost and from the rate at which the caps decrease as summer advances it can be calculated that they are not more than a few inches thick

All attempts to detect oxygen in the atmosphere of Mars have been unsuccessful The amount of oxygen is certainly not more than one thousandth part of the amount in the earth s atmosphere The red colour of Mars which is unique among the heavenly bodies provides indirect evidence of oxygen suggesting rocks that have been completely oxidized The amount of water vapour in the atmosphere of Mars is so small that it can be detected only under the most favourable conditions At the Lowell Observatory which is at an altitude of 7 250 feet Slipher in 1908 by comparing the spectra of Mars and the moon when at the same altitude under conditions of exceptional atmospheric dryness found that the water vapour absorptions were slightly stronger in the spectrum of Mars than in that of the moon

Carbon dioxide has not been detected in the Martian atmosphere There is some evidence of the existence of vegetation on Mars Seasonal changes in form and coloration of the dark areas seem to be reasonably well established and the interpretation of these changes as due to the seasonal growth of vegetation is plausible The presence of some carbon dioxide in the atmosphere may therefore be inferred Mars appears to be a world in the state that the earth will ultimately reach when the oxygen in the atmosphere will have been almost entirely exhausted by the progressive weathering and oxidation of the rocks

THE MAJOR PLANETS

The major planets Jupiter Saturn Uranus and Neptune may be considered together They are large massive planets of low mean density the visible disks of which are considerably oblate Saturn has the lowest mean density of any of the planets only seven tenths that of water The velocities of escape from all the major planets are so high that extensive atmospheres are to be expected containing an abundance of hydrogen and helium

The telescopic appearance of Jupiter and Saturn confirms the existence of dense atmospheres Markings in the form of belts parallel to the equator may be seen these are of complex structure and their details are continually changing Photographs in the infra red show many differences from those in the ultra violet but again the recorded features are continually changing so that the infra red light does not penetrate to the surface

Some theoretical results of interest have been deduced from the oblateness and mean density of these planets Jeffreys has concluded that they consist of a core of rock generally similar to the inner planets in its constitution and of about the same mean density surrounded by ice coatings of great depth above which are very extensive atmospheres According to the calculations by Wildt the rocky core of Jupiter has a radius of about 22 000 miles the ice coating is 16 000 miles in thickness and the depth of the atmosphere is about 6 000 miles The rocky core of Saturn is about 14 000 miles in radius it is covered with a layer of ice some 6 000 miles thick over which is an atmosphere extending to a height of 16 000 miles Saturn has the most extensive atmosphere of any of the planets which explains why it has the lowest mean density and the most flattened disk The pressures of these extensive atmospheres are very great, at the bottom of Jupiter's atmosphere, for example, the pressure is fully a million times the pressure at the bottom of the earth's atmosphere At a relatively small depth in the atmosphere, the pressure is great enough to compress the gas to a density nearly equal to that of the corresponding liquid.

The densities of the atmospheres are low, according to Wildt's calculations they are 0 78 for Jupiter and 0 41 for Saturn This enables most of the possible constituents to be excluded, for all known gases, in the liquid or solid state, have densities exceeding 0 3, with the exceptions of hydrogen and helium, and the only other gases whose densities in the liquid or solid state are less than the density of the greater portion of the atmosphere of Jupiter are methane and ethane It is concluded that the atmospheres of the major planets must contain large quantities of free hydrogen and helium The planets are believed to have been formed from the sun which is known to contain a large amount of hydrogen to the extent of about one third part by weight As massive planets, like the four major planets, would retain their light constituents, it is to be expected that hydrogen and helium would be present in large amount in their atmospheres

PLANETARY SPECTRA

The spectra of the major planets are of great interest Huggins discovered visually absorption bands in the orange and green in the spectrum of Jupiter These bands appear more strongly in the spectrum of Saturn, but are not found in the spectrum of the rings—a conclusive proof that they originate in the atmosphere of Saturn Uranus and Neptune show for the most part the same bands with still greater intensity, together with some additional ones In recent years, the spectra have been extended far into the infra red by Slipher, and several intense bands have been found in that region

The origin of these bands remained unknown until a few years ago Then Wildt succeeded in proving theoretically that certain of the bands agreed in position with bands of ammonia and that others agreed with bands of methane These conclusions were confirmed by Dunham who, using much higher dispersion, was able to obtain a more complete resolution of the bands into their component lines and found a complete coincidence He estimated that the quantity of ammonia gas producing the absorptions in the spectrum of Jupiter is equivalent to a layer 30 feet thick under standard conditions The amount is less in Saturn The ammonia absorptions are not detected in the spectra of Uranus and Neptune

Methane is present in much larger amount Adel and Slipher found that a 45 metre path of methane, at a pressure of 40 atmospheres, gave bands intermediate in intensity between those of Jupiter and Saturn The much greater strength of the methane absorptions in Uranus and Neptune is probably accounted for by the lower temperatures of these planets The ammonia must be frozen out of their atmospheres making it possible to see through them to a greater depth Adel and Slipher estimated that 25 miles of methane at atmospheric pressure would be required to give absorptions as strong as those of Neptune The higher gaseous hydrocarbons have been looked for in vain in the spectra of the outer planets All the absorption bands appear to be accounted for by ammonia and methane It is a grand slam

The presence of ammonia and methane in the atmospheres of the large planets is not surprising They are to be expected as a consequence of the reaction of hydrogen with nitrogen and carbon dioxide on a cooling planet Such reactions resulted in an atmosphere of hydrogen, helium, and other inert gases mixed with methane ammonia and water vapour, but with little or no carbon dioxide or free nitrogen Below this there would be a deep ocean strongly alkaline from the ammonia in solution As the temperature fell still further, the ocean would freeze It may be mentioned that an ocean consisting of one part of ammonia to two parts of water would freeze at −100° C, all the four major planets are colder than this

The ammonia in the atmospheres of Jupiter and Saturn must be nearly on the point of condensation, and the clouds over these planets may consist of droplets of liquid ammonia or even small crystals of frozen ammonia The mean temperatures of Uranus and Neptune due to solar radiation alone are about −200° C and −220° C respectively At the temperature of Neptune, the methane must be nearly ready to condense

The nature of the planetary atmospheres, about which so little was known until recently, seems now to have been solved in its broad outlines As a brief summary we find that we can divide the planets and their satellites into three groups the small ones, entirely devoid of atmospheres, the middle sized ones with atmospheres of moderate extent devoid of hydrogen or compounds of hydrogen with nitrogen or carbon but containing oxygen or compounds of oxygen, and the large ones, with very extensive atmospheres, devoid of oxygen or compounds of oxygen but containing hydrogen and compounds of hydrogen.

Facts and Theories in Protein Chemistry*

IN the last decade many investigations of an exact nature have been made on the proteins in solution and in the solid phase Unfortunately by a dissipation of the available research energy among a wide variety of proteins and by a signal absence of co operation among the researchers themselves, less significant advances have been made in the elucidation of fundamental principles than would otherwise have been the case It was a happy inspiration therefore which brought together most of the authorities on protein chemistry in Europe at the Royal Society on November 17 to compare their experiences and discuss each other s difficulties

Prof The Svedberg (Uppsala) opened the conference with a vigorous and notably wide survey of recent developments in the physical chemistry of the proteins According to precise physical measurements protein particles have such characteristic and reproducible properties that it is no longer possible to deny them the right of classification as giant molecules Sedimentation studies on native soluble proteins reveal a striking homogeneity in the sizes of individual molecules and the method of electrophoresis reveals a similar homogeneity in their free charges Measurements of protein molecular weights by sedimentation equilibrium or by a combination of sedimentation velocity and diffusion give values which, rather unexpectedly conform to a law of simple multiples

Assuming 17 600 as the unit of molecular weight, the values of some sixty native proteins so far investigated including the giant hæmocyanin molecules with weights of several millions may be expressed as multiples of this unit by factors containing powers of 2 and 3 The rule is approximate only suggesting the existence of some underlying architectural principle in the arrangement of the amino acid residues Differences in the percentage amino acid composition of proteins may explain the spread of molecular weights above and below the simple multiple value Determinations of osmotic pressure give values which agree well with molecular weights obtained by sedimentation methods X ray investigations of pepsin insulin lactoglobulin and hæmoglobin in the crystalline state have given values of 40 000 37 200 36 500 and 69 000 respectively while the ultracentrifuge gives 37 000 38 000 39 000 and 68,000

Viscosity measurements on anisotropic proteins may be correlated with the axial ratios of the corresponding molecular ellipsoids of rotation by means of equations proposed independently by Kuhn Burgers and Polson From the axial ratio the molecular frictional coefficient may be calculated, and this in turn supplies the necessary information for calculating molecular weights from diffusion data Molecular weights thus obtained from viscosity and diffusion data agree with the ultracentrifuge values only when Polson s equation which has a purely empirical basis is used Studies on the peptic digestion of egg albumin by Tiselius show that the decomposition products have a much lower electrophoretic mobility than the uncharged protein This supports the view that the constituent units of a protein particle are bound together by specific chemical linkages and that the particle is in fact a single molecule

Recent theories of protein structure proposed by Wrinch and by Bergmann and Niemann imply the chemical individuality of the protein molecule These theories are important as a stimulus to further research but caution must be observed in their acceptance In the case of Bergmann and Niemann s theory which assumes a fundamental regularity in the arrangement of the amino acid residues in the molecule certain difficulties exist For example the theory gives a molecular weight of 69 000 for hæmoglobin based on a cysteine content of 0 5 per cent and assuming three cysteine residues per molecule Ultracentrifugal and X ray methods show however, that hæmoglobin may be split reversibly into halves of approximately equal size

Dr Linderstrøm Lang (Copenhagen) emphasized the value of enzymic degradation as a method of studying the structure of the protein molecule, especially in recent years with the advent of crystalline and relatively pure enzymes Considerable care is still required in the interpretation of the results of these studies since it is now becoming clear that some fundamental change scarcely distinguishable from denaturation is a necessary preliminary to the enzymic disruption of polypeptide bonds in the protein molecule Dr D Wrinch (Oxford) gave a clear presentation with the aid of models of her cyclol hypothesis which assumes that the protein molecule is constituted of diazine and triazine rings arranged alternately in a kind of fabric which may be folded according to purely geometrical considerations The space enclosing fabric with 288 amino acid residues takes

* Substance of a discussion on The Protein Molecule held by the Royal Society on November 17

the form of a truncated tetrahedron and this represents the globular protein molecule of weight 35 000 Dr A Neuberger (London) pointed out that the presence of diazine and triazine rings in proteins is not supported by chemical facts It has never been shown that a lactam lactim tautomerism exists in peptides nor has a polymerization of peptides to cyanidine like rings been realized The chemical and enzymic behaviour of proteins is also not in accordance with the cyclol hypothesis The Bergmann and Niemann hypothesis was also criticized by Dr Neuberger on the grounds that the limits of error in the present methods of estimating amino acids are so great as to render the deductions made from them statistically of doubtful value

Dr G S Adair (Cambridge) showed that for hæmoglobin egg albumin and serum albumin the maximum values for the molecular radii calculated from measurements of diffusion made at Uppsala were not more than 5 per cent greater than the minimum values calculated from measurements of the hydration and density of protein crystals suspended in sodium phosphate buffers He also discussed the effects which salts have on the iso electric points of proteins Dr K O Pederson (Uppsala) described new work on the dissociation of proteins particularly the type of molecular splitting which one component of a binary mixture induces in the other The dissociation is more marked when a carbohydrate rich protein is mixed with a carbohydrate poor one It is also marked in serum in which there is evidence that phosphatides take a role similar to the carbohydrate The X fraction seen in the sedimentation diagram of normal serum is identical with the intermediate or β globulin seen in electrophoresis and this fraction according to Tiselius and Blix is the main carrier of the serum phosphatides Changes which affect the serum calcium for example dialysis addition of salts etc affect the sedimentation rate of the X component The effect is probably on the phosphatide linkage

Dr Pederson suggested that these and other dissociation effects are best explained by postulating that the larger protein molecules consist of small primary protein units linked into a secondary structure by means of carbohydrate phosphatide nucleic acid etc This view received striking support from Mr J St L Philpot (Oxford) who described how the sedimentation constant of casein can be altered at will to any value between 6 and 10 4 by the addition of calcium This appears to be a case of primary protein units linked by a polyvalent inorganic ion A surprising fact however is that only one boundary—an apparently homogeneous one—is present It is possible that the primary protein units are very small but if in fact they are about 100 000 in weight ($S_{w\,20^{\circ}}=6$) the absence of two boundaries might be explained by postulating an extremely mobile form of calcium casein equilibrium

Prof H H Weber (Munster) opened the afternoon session with a paper on the proteins of muscle dealing particularly with myosin Solutions of this protein show a high and anomalous viscosity and marked anisotropy of flow Solutions more concentrated than 2 per cent cannot be obtained in the disorientated state but orientated threads may be spun like artificial silk to much higher concentrations These threads resemble muscle fibres closely in swelling power tensile strength elastic properties and X ray appearances Measurements of the double refraction and the *eigendoppelbrechung* of the stretched myosin thread show that these correspond quantitatively with the values for the *Q* disks of muscle The *Q* disk consists therefore of fully orientated myosin rods Complete elastic stretching of the myosin filament results from stretching of the rods themselves the process consisting evidently in a straightening of folded filamentous molecules Myosin may be denatured by heating above 40° C the threads undergoing an irreversible decrease in double refraction and a marked contraction The view is put forward that muscle contraction consists in a chemically induced denaturation of myosin molecules which is reversible in the circumstances pertaining to muscle Dr G Boehm (Basle) showed a number of X ray diagrams of stretched myosin threads Prof K H Meyer (Geneva) developed some interesting ideas on mechanically induced molecular transformations citing the solubility and elastic changes caused in the crude material from the silk gland by simple stretching and the crystallization of metastable selenium by similar treatment He is of the opinion that blood plasma may be regarded as a supersaturated fibrinogen solution and that mechanical denaturation may suffice to explain the phenomena of blood clotting Dr W T Astbury (Leeds) referred to the elegant method of progressive piling of protein monolayers on a metal slide until it is possible to measure the thickness of a monolayer by means of a screw micrometer

Dr Evert Gorter (Leyden) discussed the behaviour of those proteins which spread easily on water surfaces and others for example fibrinogen and myosin which only do so after treatment with traces of proteolytic enzymes Spreading experiments only give information about one side of the film—fortunately the more important polar side in contact with the water The view that spread proteins are denatured is not in agreement with all the facts Denatured egg albumin does not spread and pepsin and trypsin remain active as proteolytic enzymes after spreading Spreading does not necessarily cause denaturation because the polar groups remain active and free Denaturation by shaking on the other hand results from juxtaposition of polar surfaces in the foam so that only non polar groups are exposed and the foam becomes insoluble It is unlikely also that spread proteins are denatured since these are employed widely in the architecture of living tissues Dr J F Danielli (London) pointed out that from a consideration of surface forces, it appears that the attraction between hydrocarbon residues of the amino acids are sufficient to maintain a folded globular form in the native protein These forces are insufficient however to maintain a specific rigid structure and additional chemical bonds must be postulated for this purpose

Miss D Crowfoot (Oxford) followed by Prof J D Bernal (London) discussed the technical difficulties in protein crystallography especially those arising from the weakness of the reflections and from hydration of the crystals Both speakers referred to the inadequacy of the X ray data available on the proteins and to the necessity for caution in the interpretation of the results Of the seven proteins so far examined dried insulin is the simplest having a rhombohedral cell containing only one Svedberg unit of 35 000 One cannot be certain even in the case of insulin whether the crystallographic unit is a true unit or itself consists of sub units Prof J R Marrack (London) discussed experiments with conjugated antibodies which lead to the conclusion that the antibody-antigen reaction is not due to simple combination of polar groups but probably involves specific amino acid configurations Dr F R Holiday (London) supported this view on the basis of immunity phenomena exhibited by serum albumin after incomplete digestion with pepsin

A S McFARLANE

Sir Charles Parsons and Marine Propulsion

ON December 2 at the Institution of Mechanical Engineers before an audience which included many engineers who have been closely associated with the application of the Parsons steam turbine to ships Mr S S Cook delivered the third Parsons Memorial Lecture taking as his subject Sir Charles Parsons and Marine Propulsion Born in 1875 and like Parsons a Cambridge wrangler Mr Cook has been connected for a long period with the Parsons Marine Steam Turbine Company and is well known in engineering circles for his original investigations and his memoirs on the marine steam turbine

The story which Mr Cook unfolded may perhaps be regarded by some as a thrice told tale for Sir Charles Parsons either himself or in collaboration with others placed on record in papers to technical institutions the various steps in the progress of the turbine as applied to steamships but there are features in the story which when told by others only heighten our respect and admiration for Parsons when he was faced with difficulties which would have overwhelmed men of less determination None of those who were present at the Diamond Jubilee Review of 1897 and saw the little *Turbinia* steam at more than 30 knots up and down the lines could have known that three years previously the same craft with her original machinery to the intense disappointment of Parsons and his colleagues had failed to obtain a speed of even 20 knots The spectators said Mr Cook may have been thrilled to see a tiny vessel racing down the lines at such unusual speed but their feelings could have been nothing compared with those of the few on board the vessel who had emerged so triumphantly from depressing failure into glorious success

The Parsons turbine it will be remembered was invented in 1884 For the next ten years or so it was used exclusively for driving electric generators and it was not until the compound condensing turbine had shown its superiority over the best reciprocating engine that any steps were taken to apply it to ships The speed at which it revolved seemed to some to rule it out for this purpose In January 1894 however after some preliminary work Parsons took out Patent 394 for Propelling a steam vessel by means of a steam turbine which turbine actuates the propeller or paddle shaft directly or through gearing and the pioneer company the Marine Steam Turbine Company was formed The directors of the company were the Earl of Rosse Parsons N G Clayton C J Leyland J B Simpson and A A Campbell Swinton After some experiments with models, the *Turbinia* was built She was 100 ft long and 44 tons displacement Into her Parsons fitted a single water tube boiler and a single radial flow turbine Designed to develop 1650 h p the speed of the turbine was 1600–1700 r p m A single propeller of 20 in diameter was used The results being unsatisfactory, thirty one different trials were made with different propellers, but the best speed fell short of 20 knots "At this stage,' said Mr Cook, "we cannot fail to admire the indomitable courage of Parsons One may hazard the opinion that with most engineers the experiments would have ended there The gap between the estimated speed of 30 knots and the 20 knots actually obtained was an enormous one The power varying as the cube of the speed, such a difference indicates a shortage of propulsive power in the ratio of 8 to 27 Faced with a failure of this magnitude, most men would have cut their losses, and in that case there might never have been a *Mauretania* or a *Lusitania*, no *Dreadnought* or super dreadnoughts, no *Queen Mary*—who knows ? '

To locate the failure, Parsons fitted a torsion meter on the shaft, probably the first marine torsionmeter of any type The greater part of the loss was found to be due to 'cavitation', a phenomena which had been observed by Sir J I Thornycroft and S W Barnaby during the trials of the 27 knot destroyer *Daring* They had found that if the mean pressure of propulsion over the blade area exceeded 11¾ lb, cavitation occurred In the *Turbinia* the pressure had been some 60 lb With this knowledge, and backed, as he always was, by his colleagues, the *Turbinia* was fitted with new machinery, consisting of three turbines in series driving three propeller shafts having altogether nine propellers Ready again for trial in February 1896, a speed of 32¾ knots was obtained and after other modifications, 34 knots, or four knots more than the fastest torpedo craft afloat

Mr Cook did not say how much all this pioneering work had cost, far more, it may be presumed, than the capital of £24,000 with which the company was formed Sixty years before, the Ship Propeller Company had sustained a loss of £50,000 over the historic screw driven *Archimedes*, a vessel of only a few hundred horse power The demonstration at Spithead had, however, shown the possibilities of the new means of propulsion, and a new company, the Parsons Marine Steam Company, having been formed with a nominal capital of £500,000, an order was obtained from the Admiralty for the destroyer *Viper*, and at the same time Sir W G Armstrong, Whitworth & Co ordered turbine machinery for a destroyer afterwards named the *Cobra* Both of these vessels were unfortunately wrecked in 1901 These disasters might well have seriously affected the fortunes of both inventor and his company had they not already secured the co operation of the Dennys of Dumbarton and Captain John Williamson, in the building of the Clyde river steamer *King Edward*, the pioneer of turbine-driven mercantile vessels The success of the *King Edward* had far reaching results She was soon followed by the cross Channel steamers *Queen*, *Brighton*, *Princess Maud* and *Londonderry*, and the Dumbarton built vessels *Lhasa*, *Linga*, *Lama* and *Lunka* for the British India Steam Navigation Company The marine steam turbine was now successfully launched on its astonishing career, and the end of its first decade was marked by the construction of the *Lusitania*, *Mauretania* and H M S *Dreadnought*

With the completion of these notable vessels," said Mr Cook, it might be thought that Parsons had reached his goal But Parsons was far from satisfied ' The application of the steam turbine so far was limited to fast vessels of large power Could it be used for vessels of moderate speed ? First of all, Parsons introduced the combined system in which the steam exhausting from a reciprocating engine was utilized in a low-pressure turbine The pioneer vessel with this arrangement was the *Otaki* also built at Dumbarton Then he turned to the use of toothed wheel reduction gearing He had fitted such gearing in a 10 horse-power launch in 1897, but experiments were necessary before using gearing for larger vessels So the *Vespasian* was purchased, her triple expansion engines were replaced by single reduction geared turbines and she was set to work in the North Sea Her success ushered in yet another revolution in marine propulsion To day, single reduction geared turbines are found in the majority of warships and in such vessels as the *Queen Mary* and the new *Mauretania*

But the full tale of Parsons' pioneering work in connexion with marine propulsion does not end with the direct driving turbine, the exhaust turbine or the geared turbine He was the first to make a vacuum tank for the study of model screws, he invented the vacuum augmentor, he introduced the creeping mechanism for gear cutting machines, he made exhaustive experiments on the erosion of propellers, and he was the first to appreciate the value of the Michell thrust-block Then, too, he was ever an advocate of the use of steam at high pressures and high temperatures, and in the Clyde steamer *King George V* fitted turbines working with steam at 550 lb pressure and 750° F temperature The world, said Mr Cook, is the debtor to Parsons for his faith in the turbine, his courage and perseverance, and also for the wise provisions he made for the dissemination of his knowledge and experience Parsons has won titles to fame in many spheres of applied science, but in none of brighter lustre than in the field of marine propulsion

Obituary Notices

Prof. E. M East

PROF EDWARD MURRAY EAST whose death has recently been reported belonged to the group of Mendelian pioneers who began their investigations in the first decade of the present century His most important contributions to plant genetics were in connexion with the breeding of potatoes maize and tobacco Not only was some of his work of great practical value, but he also made fundamental contributions to various aspects of plant breeding especially to inbreeding and hybrid vigour selection and the explanation of the phenomena of self sterility in plants He was one of the leading American plant geneticists of his time

Dr East was born at Du Quorn, Illinois, on October 4 1879 and graduated at the University of Illinois in 1900 He became assistant chemist and then assistant in plant breeding at the Agricultural Experiment Station of the University of Illinois, and in 1907 received the Ph D degree for a thesis entitled A Study of the Factors Influencing the Improvement of the Potato This like much of his later work, was characterized by quantitative as well as qualitative treatment of his material at a time when nearly all the early Mendelian work was mainly qualitative and descriptive in character

East was shortly appointed agronomist at the Agricultural Experiment Station Storrs Connecticut whence in 1909 he went to Harvard as assistant professor of experimental plant morphology at the Bussey Institution Since 1926 he has been professor of genetics in Harvard University East s work on inbreeding, begun at Storrs culminated in a book ' Inbreeding and Outbreeding , published in collaboration with D F Jones in 1919 His investigations of maize were especially valuable as indicating at an early period that quantitative characters such as length of cob are inherited and segregated according to the Mendelian rules Part of this work was done in collaboration with Dr H K Hayes The inheritance of flower size in interspecific crosses of *Nicotiana* was one of the earliest studies of its kind

Probably East's most important contribution to plant genetics was his masterly analysis of self sterility in tobacco, in a series of papers beginning about 1915 He first crossed *Nicotiana alata* with *N sanderæ*, and by analysis of the offspring and the crosses which could be made between them, he discovered that they fell into three groups of plants, each heterozygous for two different sterility factors or S genes These he called S_1S_2, S_1S_3, and S_1S_3 A plant which was S_1S_2, for example, could only be successfully pollinated by pollen carrying the S_3 factor The other types of pollen tube grow so slowly in the style that the flower drops off before the pollen tubes reach the ovary But he showed that by opening the buds, and so giving the pollen tubes a longer interval for growth, self fertilization could take place producing plants homozygous for particular S factors The number of such S factors in *Nicotiana* was finally increased to fifteen all allelomorphic that is representing different changes in one locus of a chromosome Similar conditions have since been found in various other plants such as red clover and *Brassica*

East was always interested in the general biological principles related to genetics, and in his later years was particularly concerned with questions of human population and related problems Mankind at the Crossroads (1923) which was widely read was a valuable study of population problems and the world s food supplies although the emphasis on over population has been partially negatived by the continued fall in birth rates A volume entitled Biology in Human Affairs was edited in 1927

During the period 1908 18 East was a collaborator in the tobacco breeding investigations of the United States Department of Agriculture and during the Great War he was chairman of the Botanical Raw Products Commission R RUGGLES GATES

Prof A K Mordvilko

ALEXANDR KONSTANTINOVICH MORDVILKO, an aphidologist and parasitologist of world repute who died on July 12 was born in 1867 in the village of Stolovichi Minsk province of Russia As a son of a minor cleric he received his general education in the Minsk seminary but then entered the University of Warsaw and after taking his degree in natural sciences in 1893 obtained a post graduate scholarship which enabled him to study first at Warsaw then at the zoological stations of Naples Marseilles and Villefranche Two years as lecturer (on animal parasitology) at the University of Kiev were followed by an appointment to that of St Petersburg then of Moscow In 1911 he joined the staff of the Zoological Museum of the Russian Academy of Sciences where he spent the rest of his life while giving lectures at the University and the Agronomical Institute

As the theme of his first scientific work written at the end of his university studies Mordvilko took the investigation of the Aphididæ (plant lice) of the Vistula region, including their bionomics and anatomy This group of insects is remarkable for exhibiting a wide range of biological phenomena of great general significance such as polymorphism, change of hosts, variations in the life cycle and types of reproduction etc Their study became his life work

The execution of this work by Mordvilko is an outstanding example of results that can be achieved by a thorough and many sided study of a single group of organisms His morphological work is remarkable for its accuracy and abundance of exactly observed details, while the biological significance of various structures was kept in view His systematic work, which resulted in a mass of most carefully described new genera and species and in revisions of whole difficult groups of aphids, can be taken as a standard for any taxonomist His main interest was, however, the intensive study of the bionomics of aphids, most particularly with regard to the evolution of the life-cycle and the change of hosts Exhaustive studies of many groups of aphids with alternate hosts led Mordvilko to the elaboration of a remarkably well documented theory of the origin and evolution of the habit of changing hosts in Aphididæ, which he has later extended to the explanation of a closely parallel phenomenon in the fungi causing rust (Uredinales) Connected with these specialized series of investigations were the more theoretical works of Mordvilko on parasitism in general, as well as on the problem of evolution and species formation

As a man, Mordvilko was almost unbelievably modest and unassuming, and, on the first encounter with him, created a wholly false impression of a bashful and probably narrow minded person, interested in nothing but his plant lice On a closer acquaintance he appeared as an exceptionally widely educated man, with far reaching and original ideas on many aspects of biology The outstanding features of his character were deeply felt kindness and sincere friendliness to everybody, outwardly expressed in a most charming quiet, endearing smile All his acquaintances were regarded by him as friends and became so, and he was incapable of making any enemies

It can be truly said that A K Mordvilko s death closes a long and most fruitful chapter in the study of the Aphididæ, to the knowledge of which he has contributed more than anybody else

B P UVAROV

DR UVAROV has outlined Prof Mordvilko s contribution to science and it remains to me to add my personal tribute to the memory of one who over a long number of years and often at great difficulty to himself proved such a valued correspondent His vast knowledge was ever at our service, he put himself to endless trouble to satisfy our needs for study material, his books and papers were generously presented He was a man of infinite pains and the embodiment of the patient investigator, taking sometimes twenty years to elucidate a single point For forty three years Mordvilko was carrying on his aphidological and other studies and during the last twenty broadened his basis so much that for years to come the suggestions contained in his works will give rise to new lines of research and though some of his theories may have to be modified, he will remain an outstanding builder F LAING

WE regret to announce the following deaths

Sir Thomas Callendar deputy chairman and managing director of Callendar s Cable and Construction Co, Ltd, a pioneer in electricity supply, on December 2 aged eighty three years

Mr W P Dreaper O B E formerly superintendent of H M Factories at Sutton Oak and Ellesmere Port, lately editor of the *Chemical World* on December 2 aged seventy years

News and Views

Publication of Scientific Research

A LARGE part of Sir William Bragg s presidential address to the Royal Society delivered on November 30, was concerned with scientific publications, and he referred particularly to the duty of the Society in connexion with the encouragement of research to secure the preparation and presentment of its results, so that they can be sufficiently appreciated and incorporated with understanding into every activity, intellectual or physical, to which they apply Though he does not think that men of science can claim to be given the direction of affairs in which their discoveries play a great part simply on that account, they are at least bound to see that acquired knowledge is rightly stated so that it can be rightly used, and he regards the vigorous action of the British Association in such matters as a commendable extension of its original purpose This consideration of opening to mankind the new fields of natural knowledge strengthens the case for reconsidering the arrangement and presentation of research results which arise from the voluminous character of present day research Commenting on the small attendances and lack of good discussion when papers are presented before a scientific society, Sir William Bragg referred to greater stress which has recently been made on the provision of opportunities for organized discussions in which some important subject of recent development was considered by the workers in that field Very satisfactory attendances have been obtained at such meetings

SIR WILLIAM BRAGG considers that the recent plan of publishing summaries of papers as an appendix to the *Proceedings* as soon as the papers are received while publication of the papers themselves is deferred in the usual way, not merely secures an earlier announcement of the discovery, but also the collection of summaries presents the general trend of research to those who are not specialists With regard to summaries, he pointed out that the ideal is more than a mere digest or shortened form of the paper, and should be different from the paper itself, in that it is addressed to a wider circle of readers, which may include the experts, but includes also many others, who should, in fact, receive the principal attention

Accordingly, he stressed the importance of insisting that the general account given in this way should be intelligible to a sufficient number of persons Sir William also queried whether it is necessary that the *Transactions* and *Proceedings of the Royal Society* should contain as much as they do at present When a new departure in experiment or theory is made and a new fact discovered or a new co relation, it is right that a careful and complete explanation should be given and if it is not too long, it is excellent that it should appear in the *Proceedings* If, however, the novelty leads as it often does, to a steady output of observation, extension, confirmation and illustration many figures and bulky tables, complete publication to the world might become unnecessary The scientific world requires a general account of progress made so that its bearing may be clear The *Proceedings* should accordingly contain papers of original discovery or fresh departure but as regards continuation papers, as they may be called, properly written summaries should be enough

Co-operation in Research

INTERNATIONAL co operation in scientific research was also discussed in appreciative terms by Sir William Bragg, and he referred to a letter received from Dr Bosch, president of the Kaiser Wilhelm Gesellschaft, inviting the co operation of the Royal Society in some scientific enterprise which would advance science and at the same time promote understanding and good will, in which an exchange of visits between representatives of the Kaiser Wilhelm Gesellschaft and the Royal Society was suggested

National Registration for Man-Power

IN the House of Commons, on December 1, Sir John Anderson, Lord Privy Seal outlined the Government s scheme for organizing the national resources in the service of the State The plan involves an immediate voluntary register of man and woman power throughout the kingdom, the publication of a handbook written in simple language as a guide to be sent to every household, a co ordinated campaign of recruiting for the Services further development of training facilities for new volunteers, making preparations for compiling in the minimum length of time a universal register under compulsory powers in the event of war The scheme received general approval from the House Though the time is not propitious for considering the scheme from the particular point of view of the scientific worker (further details must be known before this can be done), it is gratifying to think that embodied in the scheme is the possibility of the man of science being given the opportunity to give the State of his best (see NATURE of October 15), that is, not as a military subordinate , but in a position where he has ' a chance to use his imagination and knowledge co ordinated with that of his fellow scientific workers and technicians to criticize and direct, in so far as he is competent the character of operations" Thus, and only thus, can science be expected to contribute its full share to Sir John's scheme for ensuring that our man power and woman power are organized in the most effective and practical way for the voluntary service of the State

A FULL list is also to be prepared of all the key occupations which would become so essential to the nation in mobilizing for defence In addition, special arrangements are being made for the compilation of separate registers of persons possessing exceptional professional or technical qualifications Many of the scientific and technical institutions we understand, have already taken steps to compile such registers, and these will be available to the Government when required These registers together with the records already available of men included in the special list of vital occupations will constitute the National Voluntary Register In the last War many specially qualified men including men of science were engaged in the Services at posts which could have been just as ably if not even more ably filled by men with less specialized training The National Voluntary Register will go far in preventing such a waste of man power in the event of another war The Government s action in building up its scheme on a voluntary basis rather than resorting to compulsion at any rate during peace time follows true democratic principles and is therefore commendable Any doubts over this point of view should be allayed by Sir John s statement that these precautionary steps taken now will make it possible to compile a compulsory register within three weeks if necessary In the event of war of course it would be necessary to survey and marshal our resources as a whole The voluntary register would not then be enough and it would become necessary to compile a universal register under compulsion To be effective, however, such a register must be up to date and this condition can be satisfied only if it is compiled at the time when the occasion for its use arises

Indian Cultural Studies

IN the discussion which followed Mr Barger s lecture at the Royal Society of Arts on November 30 (see p 1046) interest in the future of the India Museum at South Kensington and the position of Indian studies in Great Britain will appear to have eclipsed the claims to attention of the lecturer s pioneer archæological work in Swat and Afghanistan The importance of the question raised in his concluding remarks will be accepted in palliation The anomalies and obstruction to development arising from the lack of cohesion and co operation among the eight or ten organizations in London associated with Indian studies were characterized with wit and acumen by Mr F J Richards and echoed by each subsequent speaker in the discussion while these criticisms were endorsed by Sir Richard Winstedt, who described briefly such steps, inadequate as they admittedly are, as it has been possible to take to meet these deficiencies in some measure by the provision of lectures in Indian art and archæology at the School of Oriental Studies an institution, which, it is to be noted, already has wide commitments in other directions On one point, which for some time past has been regarded with dismay among those interested in Indian cultural studies, Lord Zetland, who was in the chair, was able to reassure his audience. The risk, he said, that the collections of the India Museum might be dispersed, is at an end; and indeed, there is a prospect that the Indian sculptures at the British Museum (Bloomsbury) may be transferred to the India Museum at South Kensington.

THE discussion was an indication, if such were needed, of the existence of a strong body of instructed public opinion, restricted though it may be in extent, that a remedy must be sought for the present highly unsatisfactory position of Indian cultural studies. That there is need for an organized centre devoted to them may be argued on the ground of public policy in view of the future relations of Great Britain and India; but it is also at the moment in pressing need of educational facilities in London. Contrary to the contention frequently advanced, Mr. Richards, from his experience as an honorary lecturer on Indian archæology in the University of London of some years' standing, was able to testify to the demand for instruction in this group of subjects; while the gratitude with which the rearrangement of the Indian collections at South Kensington on cultural lines has been acclaimed is a measure of the general appreciation of the possibilities of further systematic development in teaching and research. Whether provision of an organized centre of teaching and research can most suitably be made in connexion with the India Museum on the lines suggested in relation with the University of London is a matter for further consideration. The position of the Victoria and Albert Museum, of which the India Museum is at present a part, under the Board of Education, is anomalous. It presents difficulties, not insuperable, no doubt, which render comparison with other museums exercising teaching functions beside the mark, even though here, as in other of the national collections in London, the system of guide lecturers exists for instructional purposes. This system might well be extended to meet needs of more advanced instruction. In any event, no scheme of instruction can attain efficiency without the closest association with the collections and staff of the India Museum; nowhere else in Great Britain is there the systematic knowledge and the carefully graded series of specimens, for example, in pottery or beads, which may not be sufficiently spectacular for exhibition in public galleries, but are of the indispensable groundwork in instruction.

Mr. E. Thurlow Leeds

MR. EDWARD THURLOW LEEDS, keeper of the Ashmolean and the Department of Antiquities in the University of Oxford, whose election to a professorial fellowship at Brasenose College is announced, holds a position of distinction among archæologists for his carefully documented studies in Celtic and Saxon art and archæology. Mr. Leeds was educated at Uppingham and Magdalene College, Cambridge, on which foundation he was a scholar. He joined the staff of the Ashmolean as an assistant in the Department of Antiquities in 1908. Since the Great War, Mr. Leeds's influence on the teaching of archæology at Oxford has been profound; and his appointment as keeper of the Ashmolean on the death of Dr. D. G. Hogarth was regarded as both opportune and a well merited recognition of his efforts in developing these studies in the University. Mr. Leeds was a vice-president of the Society of Antiquaries of London in 1929–32 and Rhind lecturer in archæology in 1935, his lecture on 'Early Saxon Art and Archæology' afterwards appearing in book form. Mr. Leeds's responsibilities as keeper are now to be enlarged by the addition of an Institute of Egyptological Studies to the Museum. This is in accordance with a decree passed in Congregation of the University on November 29, which gives practical effect to the bequest, accepted in January last, by the late Prof. F. Ll. Griffiths, professor of Egyptology in the University of Oxford, and Mrs. Griffiths for that purpose. Although the Institute will form a department of the Ashmolean, it will be under the control of its own committee of management, a representative body.

The Scientist and the Philosopher

FOR his Friday evening discourse at the Royal Institution on December 2, Viscount Samuel took as his subject, "The Scientist and the Philosopher". He said that in the complicated civilization of the modern world a division of labour is necessary, but this is sometimes carried to excess. The separation between science and philosophy gives an example. This is not, as it might seem, a merely abstract and academic matter, remote from affairs. Action is ruled by ideas. Philosophies of some kind move the nations. Every land resounds with the tramp of armies, and the air throbs with the droning of their aircraft. Behind the armies are the dictators or the parliaments. Behind them are the political creeds, and behind the creeds are the philosophers who inspired them. Our age needs above all else a new synthesis of science and philosophy together with religion, to supply the ideas that should guide the modern world. There are many things that philosophy should accept from science. Scientific workers in their turn may derive help from philosophy. They might be induced not to attribute physical qualities to human mental concepts, such as space; nor to assume that, because phenomena are out of reach of our means of observation, it follows that Nature does not determine them according to uniform laws. Two fundamental questions remain unsolved, and philosophers await the answers: from physics, the cause of gravitation, and from physiology the nature of thought. It is often said that these can never be solved; but if we view what has been the progress of knowledge between the stone age and now, further advances such as these are not inconceivable; they may indeed be close at hand. There is nowadays a marked convergence of science and philosophy. Let this develop and let religion, guided by reason and conforming to fact, take her place in the great synthesis; then man will feel at one with himself, will confront with new energy the confusions and perils that beset him, and be able to march with confident step into the future.

From Magic to Science

A MEETING of the Society for the Study of Alchemy and Early Chemistry took place on December 7 at Queen Mary College London when Mr J C Gregory delivered a lecture entitled From Magic to Science Mr Gregory traced the interplay between reliance on magical efficacies on one hand and a recognition of rationally conceived agencies or natural laws on the other Thus alchemy *complicated by mysticism and* animism, had its rational theory as in the Aristotelian Doctrine of the Elements, and its reliance on laboratory procedure It had also its magically conceived efficacies such as the reputed powers of the Philosopher s Stone As the rational recourse constantly invaded magic so the magical recourse influenced rational procedure There came a point however, when the magical belief was discarded to make way for a more scientific concept of natural laws Mr Gregory pointed out that the seventeenth century corpuscle was a great scientific rationalizer of magic Boyle discreetly reserved however some medicinal virtues for gems as a scientifically purified magic His reduction of the potency in the Powder of Projection or in the Alkahest to corpuscular catalysis illustrated the rationalization of magic by science Though the master Therion still hoped to vindicate the thaumaturgic agent of alchemy he deferred to present thought by applying the method of science to the art of magic

International Telephone Conference

A MEETING of the Comité Consultatif International Téléphonique (C C I F) was opened in London on December 5 by Sir George Lee engineer in chief of the Post Office The conference is being attended by about a hundred delegates from fourteen different countries and will continue until December 17 Most of the delegates are telephone experts and they are discussing various technical problems encountered in the operation of international line telephone communication The work of the Conference is divided between two committees, the first of which is studying the technical problems of long distance telephone calls, including the suppression of noise and the improvement of quality of reproduction of the human voice The second committee is studying the special problems encountered in carrier current telephony in which a number of conversations are carried simultaneously as a modulation of a high frequency current on one pair of wires As an extension of this problem the question of providing international circuits for television programmes will be considered The holding of the conference in London is particularly opportune for during the past fifteen years direct connexions with the majority of the capital cities of Europe over the ordinary land line network have been established in London which with the development of long distance radio links has thus become the main world switching centre for inter continental telephone calls

Radio Communication for the Colonies

ACCORDING to a statement in *The Times* of November 30, the chairman and managing director of Messrs Cable and Wireless, Ltd has made an offer to the Government to create a system of wireless telegraphic and telephonic communication throughout the Colonial Empire without cost to the administrations or the peoples concerned The scheme provides for the installation of radio equipment at each of the cable stations where no commercial wireless service is already in operation The Company will bear the cost of installation and any experiments necessary, and while the new facilities will be complementary to the existing cable services their commercial use will bring additional revenue to the Company The scheme is of great significance from strategic and economic points of view, the wireless stations will ensure a second line of defence for inter Colonial communication and provide the Colonies with a means for their keeping in touch with aircraft and ships in home waters in addition Imperial development and unity will be promoted through an extension and cheapening of communications The establishment of the service would also enable a great deal of valuable technical research to be carried out in connexion with the propagation of waves to various parts of the world In view of the advantages accruing to the Colonies under the proposals the offer has been made on the assumption that the Company would be given a non restrictive licence on broad lines

Memorials to Inventors

ON November 17 and 24 memorials were unveiled respectively to John Boyd Dunlop (1840 1921) who fifty years ago invented the pneumatic tyre for cycles and to Joseph Aspdin (1779 1855) the inventor of Portland cement The memorial to Dunlop is a plaque which has been erected at Fort Dunlop, Birmingham the great works of the Dunlop Rubber Company Dunlop who was born at Dreghorn, in Ayrshire became a student at the Edinburgh Veterinary College and in 1867 started in practice as a veterinary surgeon in Belfast It was while living at 28 May Street in that city that he made his first pneumatic tyre and applied it to his son s tricycle the following year 1889 Harvey du Cros (1846 1918) formed a company in Dublin for the manufacture of pneumatic tyres and from this has sprung the world wide tyre industry of to day There are already memorials to Dunlop in Edinburgh and Belfast The memorial to Aspdin consists of a plaque and memorial gates at St John s Church Wakefield where the inventor is buried Aspdin was born in Leeds and became a stonemason His patent for Portland cement is dated October 21 1824, and on the hundredth anniversary of that day the president of the American Portland Cement Association Mr F M Kelley unveiled a bronze tablet to the memory of Aspdin which the Association had erected on the plinth of two of the columns supporting the roof of the Leeds Town Hall The memorial at Wakefield was dedicated by the Bishop of Wakefield and unveiled by Lord Wolmer on behalf of the Cement and Concrete Association Little is known of Aspdin s career After taking out his patent he started manufacturing cement at Wakefield and one of the first important structures in which it was used was Brunel's Thames tunnel. Aspdin's son William (1816–64) played a considerable part in the development of the cement industry and erected works in Germany, where he died.

British School of Archæology at Athens

AT the annual meeting of the British School of Archæology at Athens which was held at Burlington House, Piccadilly, London, W.1, on November 29, when the Crown Prince of Sweden was in the chair, Mr. J. D. S. Pendlebury gave an account of his recent excavation of the city of Karphi in Crete. This was one of the cities on the hills surrounding the plain of Lasithi, and its great interest lay in the fact that it contained an example of a large house which probably dated from within two generations of the Trojan War and thus afforded an excellent illustration of the house of Homeric times. The city was situated on an exposed spot with cliffs on three sides, that on the north having a sheer drop of 2,000 feet. It contained two cemeteries, a temple and, among other buildings, as already mentioned, a house, the largest of the period yet found. It is interesting to note that the roofing system of the whole town is that still in use among Cretan peasants. It would appear that bronze age civilization came to an end in Crete about 1100 B.C., when there was an invasion of people from outside who introduced the Greek language and settled at first near the sea. The old Minoans found sanctuary in the hills where they continued to live on. Occupation at Karphi came to an end some two hundred years later, at about 900 B.C. Its evacuation apparently was peaceful, its inhabitants no doubt then considering it safe to live in a less exposed situation. In the course of the meeting, two announcements of no little importance were made. Prof. J. L. Myres, in moving the adoption of the annual report, stated that news had been received by the last mail of the discovery of an important Minoan tomb at Knossos, which was to be investigated at once; and Sir John Forsdyke announced that owing to the increase in the Government grant from £500 to £1,000 per annum and the coming into operation of the Richard B. Seager bequest, the activities of the School in excavation would be considerably extended in the coming year.

Woad Mills

AMONGST the many at one time flourishing industries connected with agriculture carried on in Great Britain was that of the cultivation and preparation of woad, and in a paper read by Mr. Rex Wailes before the Junior Institution of Engineers on November 25 is described its cultivation in gradually decreasing quantities down to 1932, when the last crop in the world was gathered at Boston in Lincolnshire and prepared for market. Woad has been grown for centuries in Great Britain and prepared for market as a mordant or fixer for indigo dye. Its use in dyeing requires much skill and its preparation is a lengthy process. The plant rapidly exhausts the soil in which it is grown, necessitating frequent removal of the woad mill and appurtenances to fresh sites. As in the case of many ancient industries, the woad mill evolved by village craftsmen seems peculiarly well fitted for its purpose. It ground the leaves into small pieces and after about an hour the mill was stopped and the pulped mass taken out and kneaded into balls about 6 in. in diameter; these were stacked on trays in open tiers of gratings where they dried for some weeks and were then removed to store rooms preparatory to couching, the most difficult operation in the preparation of woad. The balls were first broken up by the rollers in the roller house and then taken to the couching barn near by and spread on the floor to a depth of about 3 ft., watered, and allowed to ferment. During this process temperature was carefully controlled and not allowed to exceed 125° F. The woad was turned daily at first and less frequently thereafter, the total time being 6–8 weeks. After couching, the woad was dried and rammed into barrels, its appearance then being like compressed peat or plug tobacco.

Technical Training at Leeds

THE City of Leeds College of Technology enrolled in 1937–38 more than four thousand students, of whom all except 14 per cent attended evening classes only. In a report presented by the Principal on the occasion of a distribution of awards by Prof. Lancelot Hogben on November 29, an appeal was made to employers to promote a largely increased attendance at part-time day courses of technical training in principles. That serious practical difficulties stand in the way of large scale releases of employees for this purpose was freely admitted, but few would be found to deny that there is a crying need for constructive effort to make good the gaps in vocational education resulting from the obsolescence of the apprenticeship system in industry. In the great majority of trades at the present day the only qualification for receiving the pay and status of a journeyman is the attainment of the age of 21. The Principal wants industrialists to co-operate with the College in devising schemes, separate for each trade, such as are already in operation in the engineering trade in the Midlands, for issuing some agreed form of apprenticeship certificate giving full recognition to workshop training as well as to technical college work.

Standard Time

THE recent unveiling in Toronto, announced in *The Times*, of a bronze plaque of Sir Sandford Fleming recalls that it was only sixty years ago that he proposed the system of standard time now universally used. The advent of railways and telegraphs to North America made the continued use of local time an inconvenient practice. The railways began to use their own time, which was seldom in accord with the local time of any place on the line. When more than one railway served a town, there were usually two or more railway times as well as the local time, and confusion was rife. Fleming, who was a Scot, became chief engineer of the Canadian Pacific Railway, and he realized that something must be done to end this state of confusion. In 1878, he proposed to the Canadian Institute in Toronto that the solution lay in dividing the globe into 24 time belts each of fifteen degrees of longitude, each belt to mark a difference of one hour in time. The Marquis of Lorne, at that time the Governor General, submitted the proposal to the British Government, which, however, did not approve. The Tsar of Russia then initiated an international conference in Vienna in 1881 to discuss the matter. This led to a second conference in Washington in 1884 and the almost universal adoption of the proposal after the railways of Canada and the United States had already put standard time into use.

Ramsay Memorial Fellowship

THE following Ramsay Memorial fellowships for the year 1938–39 have recently been awarded: Dr. Vernon Hollis Booth, a British fellowship of £300, tenable for two years, at the University of Cambridge, Mr. Donald McNeil, a Glasgow fellowship of £300, tenable for two years at the University of Glasgow, Dr. Alfred Epprecht, a Swiss fellowship of £300, tenable for one year, at the Imperial College of Science and Technology, London. The Trustees have renewed the following fellowships for a second year: Dr. A. E. Alexander (British fellow), at the University of Cambridge, Dr. E. de Salas (Spanish fellow), at University College, London, Dr. J. J. Hermans (Netherland fellow), at University College, London, M. Jean Monvoisin (French fellow) at the Royal Institution, London, Mr. Hazime Oosaka (Japanese fellow), at University College, London, Dr. E. C. Stathis (Greek fellow), at the Imperial College of Science and Technology, London.

Announcements

PROF. H. SHAPLEY, director of the Harvard College Observatory, Cambridge, Mass., has been elected a member in the Section of Astronomy, and Prince Louis Victor de Broglie, of the Institut Poincaré, Paris, a member in the Section of Physics, of the Royal Swedish Academy of Sciences.

PROF. EMILE ARGAND, professor of geology, mineralogy, petrography and palæontology in the University of Neuchâtel, and Dr. E. A. Stensio, director of the Department of Palæozoology in the Naturhistoriska Riksmuseum, Stockholm, have been elected foreign fellows of the Geological Society of London. Prof. H. von Eckermann, assistant professor of mineralogy and crystallography in the University of Stockholm, Prof. D. W. Johnson, professor of physiography in Columbia University, and Prof. A. A. Öpik, professor of geology in the University of Esthonia, have been elected foreign correspondents.

AT a meeting of the Royal Society of Edinburgh held on December 5, the president, Sir D'Arcy Thompson, showed and gave to the Society a copy of the billet of the corresponding meeting sixty years ago (December 16, 1878), when he had read a paper "On Ulodendron and Halonia" to the Society. This paper, communicated by Sir Wyville Thomson, was afterwards published by the Geological Society of Edinburgh, along with a plate drawn by another young man, known later on to all geologists as Benjamin Peach.

HONORARY degrees have recently been conferred by the University of Paris on the following: Prof. Szent Gyorgi, professor of medical chemistry in the University of Szeged faculty of medicine, Dr. S. P. L. Sörensen, director of the chemical section of the Carlsberg Laboratory, Copenhagen, and Dr. Karrer, director of the Institute of Chemistry, University of Zurich.

PROF. JULES BORDET, director of the Pasteur Institute of Brussels, was presented with the Grand Cross of the Legion of Honour at the opening meeting of the Congress of the Association of French-speaking Microbiologists.

THE Sir Frederick Hobday Presentation Fund has now reached its first £1,000 contributed by about 850 subscribers. The committee has decided to continue its work in order to obtain the amount necessary for the object which Sir Frederick Hobday had in view, namely, the endowment of a chair of comparative medicine. Subscriptions should be sent to the honorary secretary, Mr. E. I. Cox, 3 St. John's Avenue, S.W.15.

THE Annual Conference of the Geographical Association will be held at the London School of Economics on January 3–6, 1939, under the presidency of Sir Thomas Holland. The subject of Sir Thomas's address will be "The Geography of Minerals". Further information can be obtained from the Clerk, Geographical Association, Municipal High School of Commerce, Princess Street, Manchester, 1.

THE annual meeting of the Institute of British Geographers will be held in the London School of Economics on January 5–6. Further information can be obtained from Mr. J. N. L. Baker, The University, Oxford.

THE twenty-seventh annual Conference of Educational Associations will be held at University College, London, W.C.1, on January 2–9, 1939, under the presidency of the Right Hon. Lord Macmillan. The subject of the presidential address will be "The Function of the University". A joint conference on "The University in a Changing World" will be held on January 5. Further information can be obtained from the Conference Secretary, Gordon House, 29 Gordon Square, W.C.1.

THE Cambridge University Press is to publish shortly "Karl Pearson", a memoir consisting of two articles by his son. It surveys his life from his earliest days, giving extracts from letters to show the development of his philosophy, and details of his many activities. It is illustrated with many portraits, and there are appendixes summarizing his unpublished lectures and reports.

Blue Sunlit Aurora Rays and their Spectrum

IN the morning of September 15 last, between 3^h and 4^h M T T (sunrise in Oslo 5^h45^m), blue sunlit aurora rays were observed like those of March 23 1920[1] Simultaneous photographs from two stations showed that the blue part was lying from about 250 km to 650 km above the earth We succeeded in taking some good spectra which were very similar to a most interesting spectrum taken by Lord Rayleigh[2] of the aurora of May 14 1921 In Fig 1 is seen the spectrum taken on Agfa Isopan plate *ISS*, exposure from 2^h35^m to 3^h55^m, of the summits of sunlit aurora rays among which the greater part were blue The small spectrograph used was loaned by the Auroral Observatory in Tromsö The wave lengths have been measured by Dr Harang and are written above the spectrum

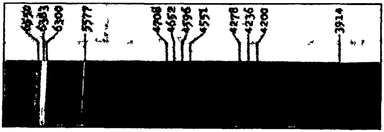

Fig 1

SPECTRUM OF THE SUMMITS OF BLUE SUNLIT AURORA RAYS AT A HEIGHT OF ABOUT 400 KM 650 KM TAKEN WITH A SPECTROGRAPH FROM THE AURORAL OBSERVATORY TROMSÖ

TABLE 1 RELATIVE INTENSITIES

Blue sunlit rays		Strong curtains in shadow	
6550 A	Not well separated from the next one	6550 A	27
6300	245	6300	29
5577	100	5577	100
4708	6	4708	no trace
4278	130	4278	20
3914	1[illegible]3	3914	2

TABLE 2 RELATIVE INTENSITIES

Wave length (A)	Blue rays	Common aurora (Vegard)
4708	100	100
4652	97	9
4596	85	44
4551	70	26
4278	100	100
4236	9	24
4200	35	8

In Fig 2 is seen a spectrum of the same rays with another spectrum of lower yellow green curtains in the earth s shadow going down to about 92 km Both spectra were taken on Agfa Isopan *ISS* of the same stock with a spectrograph of great light power but small dispersion

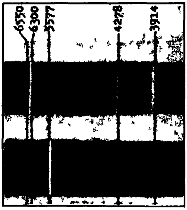

Fig 2

SPECTRA TAKEN WITH A 60° PRISM SPECTROGRAPH AND SMALL DISPERSION ABOVE THE SAME BLUE SUNLIT AURORA RAYS AS IN FIG 1 BELOW YELLOW GREEN CURTAINS HEIGHT OF LOWER BORDER ABOUT 92 KM

All spectra were taken from my auroral station in Oslo by my assistant Mr Herlofson

By courtesy of my colleague V M Goldschmidt, records were made of these spectra using his large Zeiss photometer I am indebted to Dr Oftedal for doing this work and to Mr Herlofson for measuring the photometer records Table 1 shows the great difference between the two spectra in Fig 2

From this it is seen that either the relative intensity of 6300 to 5577 A has increased 8 times of 4278 A 6 5 times and of 3914 A 7 times in going from the yellow green curtains to the blue rays or else that the intensity of the line 5577 A has enormously decreased This agrees with my visual observations[3] on March 23 1920 and with Lord Rayleigh s observations on May 13–15 1921 as regards the intensity of λ5577A to 4278A and 3914A

Of special interest is the enhancement of a series of nitrogen bands in the blue and violet relative to the bands 4708 A and 4278 A seen in Fig 1 as well as in the spectrum published by Lord Rayleigh Table 2 gives the relative intensities for these bands, assuming absorption and plate sensitivity to be constant for each of the intervals 4551 4708 A and 4200 4278 A and the corresponding relative intensities for ordinary auroras according to Vegard[4]

Experimental Scrutiny of the Influence of Gravitation on Light

IT is remarkable how few decisive verifications of second order relativity in physical systems have been effected. one can only recall the experiments of Michelson and Morley, Rayleigh and Brace, and FitzGerald and Trouton. It is therefore desirable that the very remarkable investigation by H. I. Ives and G. R. Stilwell at the Bell Telephone Laboratories in New York, entitled An Experimental Study of the Rate of a Moving Atomic Clock [1], which has recently come into my hands, should not be overlooked. They have succeeded in measuring the second order change in the free periods of the hydrogen atoms in canal rays flying transverse to the line of sight, which the finite speed of light demands, and in closely verifying the theoretical frequency factor $(1 - v^2/c^2)^{1/2}$

This is because the periods when transposed from the observer's to the vibrator's own frame should remain unaltered, if there is a universal standard of intervals of time the same for all free vibrators.

We may pursue the subject into the influence of gravitation. if its field belongs to the vibratory system, the same invariance of period referred to the system itself ought to hold[2]. But it produces a velocity v given by the equation of scalar energy $\frac{1}{2}mv^2 = mV -$ constant, where V is the potential of the field. hence we would infer that the field is responsible for a factor of change of frequency $(1+2V/c^2)^{1/2}$, so that the product of the two factors should be unity up to the second order.

This is just the expression for the influence of gravitation that has been adopted by the observing astronomers, following Einstein, but their efforts to verify it have been embarrassed by various disturbing influences.

It is to be noted that for vibrators in the gravitational field of the high solar atmosphere v is negligible, for their downward motion is not free as they are supported by collisional forces. it follows that such influences also produce their own changes in the frequency of vibration, which would be not easy to specify directly. This unsettles the results of stellar and nebular measures.

One notes that the transverse influences are verified on the periods of diatomic hydrogen and the elusive triatomic hydrogen, but the monatomic form does not appear. Null second order effect of a uniform magnetic field is found, which agrees with theory, for such a field would not affect the circuital equations.

It comes out that the unmodified frequencies are exactly the same for the diatomic and the triatomic hydrogen vibrators, which as the experimenters remark is a significant result. The absence of monatomic hydrogen vibrators may perhaps be ascribed to the smallness of these particles and the resulting rarity of stimulating encounters.

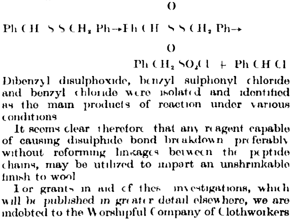
Reactivity of the Sulphur Linkage in Wool

PRESENT DAY methods of imparting an unshrinkable finish to wool depend for their success on the formation of a gelatinous degradation product of keratin on or under the surface scale structure of the fibres. As a rule the necessary degradation is brought about by chlorine, the layer of cortex immediately underlying the scales being attacked preferentially when an aqueous solution of chlorine is used[1]. The attack may, however, be restricted to the surface of the fibres by taking advantage of the inaccessibility of dry fibres to reagents of comparatively low molecular weight[2], as for example in the processes where gaseous chlorine[3] or solutions of chlorine in inert organic solvents are applied to wool of low water content.

From first principles it is evident that the degradation essential for unshrinkability must be realized by the fission of disulphide bonds or peptide linkages, the former being the more important. Apart from the fact that chlorine is known to cause disulphide bond breakdown, proof of this generalization is afforded by the fact that chlorine peroxide, which converts cystine into cysteic acid[4], imparts an unshrinkable finish to wool when applied from solution in carbon tetrachloride[5]. Further, since potassium permanganate, manganese heptoxide and Caro's acid can, under the correct conditions, be used to impart an unshrinkable finish to wool[5], it seems clear that any oxidizing agent capable of causing disulphide bond breakdown is *ipso facto* a potential agent for producing unshrinkability.

As regards the recent process utilizing a solution *of sulphuryl chloride in white spirit*[6], disulphide bond breakdown is again the cause of unshrinkability, because we have been able to show that sulphuryl chloride reacts with dibenzyl disulphide in the following manner at 37° C.



$$\mathrm{PhCH_2{\cdot}S{\cdot}S{\cdot}CH_2Ph \rightarrow PhCH_2{\cdot}\overset{O}{S}{\cdot}\underset{O}{S}{\cdot}CH_2Ph \rightarrow PhCH_2SO_2Cl + PhCH_2Cl}$$

Dibenzyl disulphoxide, benzyl sulphonyl chloride and benzyl chloride were isolated and identified as the main products of reaction under various conditions.

It seems clear therefore that any reagent capable of causing disulphide bond breakdown, preferably without reforming linkages between the peptide chains, may be utilized to impart an unshrinkable finish to wool.

For grants in aid of these investigations, which will be published in greater detail elsewhere, we are indebted to the Worshipful Company of Clothworkers (London) and the International Wool Publicity and Research Secretariat.

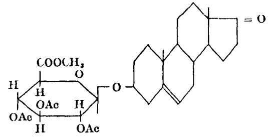
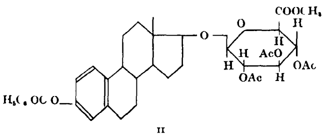
Synthesis of Sexual Hormone Glycuronides

THE importance of glycuronic acid lies in its property of condensing with hydroxylic compounds to produce the so called coupled glycuronic acids. In this way these substances become soluble in water and therefore also in urine. From the researches of Cohen and Marrian[1], Cohen, Marrian and Odell[2], as well as those of Venning and Browne[3], glycuronic acid also plays a part in the mechanism of the elimination of the sex hormones. These investigators succeeded in isolating and identifying œstriol glycuronide in an amorphous form (Marrian), and pregnandiol glycuronide in a crystalline condition (Venning and Browne), from pregnancy urine. The crystalline sodium salt of œstriol glycuronide proved to be about thirty times as weak as free œstriol on a subcutaneous injection into adult ovariectomized mice. Pregnandiol glycuronide was claimed by Venning and Browne to be the form in which progesterone is eliminated. The latter cannot couple, however, and must first of all be converted into the hydroxylated pregnandiol, within the organism. I wish to report here the synthetic preparation of the coupled glycuronic acids of dehydroandrosterone and of α œstradiol monobenzoate.

Methyl α acetobromoglycuronate prepared according to the directions of Goebel and Babers[4], and the corresponding hormones, were the starting materials. When the synthesis was carried out in indifferent media, such as, for example, benzene in presence of silver carbonate, condensation took place with the elimination of bromine and the simultaneous formation of an oxygen bridge and the production of the corresponding derivative of the hormone glycuronide. Thus dehydroandrosterone furnished the acetylated glycuronide of the constitution shown in (I), as a well defined, crystalline substance, m p 194–196° (uncorr) $[\alpha]_D^{\circ}$ − 8 4° in chloroform



I



II

α Œstradiol benzoate afforded a similar, well defined, crystalline substance, m p 189 191° (uncorr) with constitution shown in (II). This substance is optically inactive.

Hydrolysis with barium hydroxide in methyl alcoholic solution splits off the acetyl and the benzoyl as well as the methyl groups, with the production of the crystalline barium salts of the hormone glycuronide. The coupled hormone — glycuronic acids are obtained in glistening, mother of pearl like scales by treating the barium salts with sulphuric acid.

(1) Dehydroandrosterone glycuronide melts at 262 264° (uncorr), the colour turning brown and decomposition taking place.

(2) Œstradiol (17) glycuronide melts after shrinkage at 191–194° (uncorr) while the colour turns yellow and decomposition takes place.

On account of lack of material, the hormone glycuronides have not yet been obtained in an analytically pure state. They are fairly readily soluble in hot water.

The following preliminary data on the biological activity of the two preparations may be given. A daily dose of 20 γ of dehydroandrosterone glycuronide per capon dissolved in propylene glycol and smeared on the comb on each of four successive days was inactive. 77 γ per capon gave a sectional comb growth of 14 per cent after five days. 120 γ of œstradiol glycuronide injected subcutaneously during 24 hours in three doses of 40 γ, produced heat in castrated mice, 12 γ was inactive. The considerable loss of activity of the substances in the form of a glycuronide compound is similar to that found by Marrian and collaborators for œstriol glycuronide.

We are now determining the physical constants of the analytically pure preparations and preparing other glycuronides.

Tyrosinase and Catechol Oxidase

THE nature of tyrosinase has been under discussion for a very long time. Raper and his school[1], Graubard and Nelson[2], and Keilin and Mann[3] believe it to be a distinct enzyme, different from catechol oxidase. Onslow and Robinson[4], McCance[5], and Richter[6] believe it to be a catechol oxidase plus o chinone plus dehydrogenase. Kubowitz[7], whose work appeared in a recent issue of the *Biochemische Zeitschrift* whilst we were preparing for publication our results, states that it is identical with catechol oxidase. Recent books[8,9] appear to accept the first of these views.

The tyrosinase that we have worked with was extracted from *Sepia*. The action of the enzyme from this source has been shown by one of us[10] to be identical with that of Raper's meal worm tyrosinase. In agreement with most of the workers mentioned above, we have found that the partially purified tyrosinase acts on tyrosine with a very long induction period.

This induction period can be reduced, as has long been known, by adding a trace of o diphenol.

We have found that this 'activating effect' consists merely of the reduction of the induction period. After a short autocatalytic period, evidently depending on the quantity of the o diphenol added, the reaction in the two systems proceeds at equal speeds

Moreover, the rate of the oxidation process, as followed in Warburg respirometers, is linear for a very long time

The simplest explanation of these facts lies in the assumption of an equilibrium

Tyrosine + o chinone ⇌ dioxyphenylalanine + catechol,

when catechol is added to the system This has been demonstrated by simple chemical means, in the absence of an enzyme, by the addition of a recently prepared o chinone solution to a tyrosine solution and subsequent extraction with ether We found a considerable decrease in the concentration of tyrosine, and a *proportional increase in the concentration of* diphenol

Thus we think that the only enzymatic step in the phenol oxidation is the dehydrogenation of the diphenols in the corresponding o chinone, whilst the oxidation of the monophenols in the corresponding o diphenols is a simple chemical process occurring automatically These results suggest that the presumption of a tyrosinase (monophenolase) is not necessary to explain the tyrosine (monophenol) oxidation, and consequently tyrosinase (monophenolase) need not exist at all

Details of our work will shortly appear elsewhere

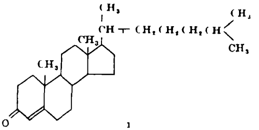
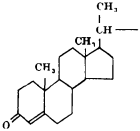
Photochemistry of Δ^4-Cholestenone

THE carcinogenic properties of œstrone, and the close structural relationship between the powerful carcinogenic hydrocarbon methylcholanthrene and the steroids, makes the hypothesis appear justified that perhaps light cancer of the skin is due to photochemical conversion of steroids situated in the skin into carcinogenic products We have therefore, in collaboration with Prof L Halberstaedter (Jerusalem), begun to investigate the changes brought about by ultra violet irradiation of steroids, and report here our results with Δ^4 cholestenone (I)

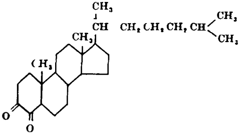
So far, only sterols seem to have been investigated in this way (ergosterol, cholesterol) but recently the photo oxidation of a hydrocarbon, $\Delta^{2,4}$ cholestadiene, leading to a peroxide, has been studied by Skau and W Bergmann[1] and by Butenandt and Kudszus[2] When a hexane solution (5 per cent) of Δ^4 cholestenone[3] is exposed to the full light of a mercury arc[4], the formation of an insoluble, well crystallized substance sets in immediately (The same phenomenon has been observed in benzene solution) This substance, which proves insoluble also in the other usual organic solvents, is conveniently recrystallized from ethyl malonate or ethyl succinate, forming needles not melting up to 360° C The high melting point, insolubility and analysis point to a dimolecular reaction product (formally analogous to ergopinacol and similar substances), the analyses seem to prove the formula $C_{42}H_{62}O_2$ (calc C, 84 2, H, 10 3, found C, 83 85, 83 97, 83 62, 84 19, H, 11 0 11 0, 10 7 10 5), which is derived from



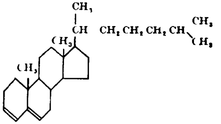
I



II



III



IV

cholestenone (I) by loss of six carbon atoms and dimerization of the remainder of the molecule

The insolubility of the substance has prevented so far the elucidation of its structure by degradation reactions, so it can only tentatively be assumed that the side chain of (I) is split at C_{20} and dimerization occurs at this point (II) If so, the skeleton of progesterone is formed from that of cholesterol—so far no conclusive attempts have been reported to convert cholesterol into sex hormones by biological means[5]—and our observation is an interesting analogue of the photochemical decomposition of the side chain in lactoflavin to form 'lumi lactoflavin'[6], but in this case hydrogenation of the involved carbon atom occurs instead of dimerization

The formation of the high molecular product (II) is accompanied by the production of a resinous by product, which separates partly on the walls of the quartz vessel and prevents further interaction with the mercury radiation when the vessel is emptied and cleaned the solution deposits anew the above substance The nature of this by product has not been elucidated

When in the irradiation of cholestenone (I) oxygen is not rigidly excluded, a second product is formed through photo oxidation It can be isolated from the hexane mother liquor of (II) by evaporation trituration of the residue with isopropylalcohol and recrystallization of the insoluble part from butyl alcohol, and forms prismatic needles, m p 157° C ($[\alpha]_D = +23\ 3°$ in chloroform) According to the analysis (found C, 80 8, 80 3, H, 11 0, 10 9, calc for $C_{27}H_{44}O_2$ C, 81 0, H, 11 0 per cent), the substance is the known[7] cholestane 3 4 dione (III), like the substance itself its condensation product with *o* phenylene diamine, however, showed a higher m p (228°, from isopropyl alcohol) than recorded in the literature (found N 5 8 calc for $C_{33}H_{48}N_2$ N 5 9 per cent) The course of this photo oxidation is analogous to the formation by means of selenium dioxide of 3 4 dihydroxy derivatives from cholesterol and dihydro ergosterol[6]

Finally, it may be put on record that cholesteryl acetate, on irradiation is mostly resinified, from the resin it has been possible in some instances to isolate—by distillation *in vacuo* (b p 228 230°/2 mm) and trituration of the distillate with methanol and acetone—$\Delta^{3\ 5}$ cholestadiene (IV)[8], from acetone, m p 76°, $[\alpha]_D = -100°$ in chloroform (found 88 0, H, 11 9, calc for $C_{27}H_{44}$ C, 88 0, H 12 0 per cent) As cholesteryl acetate can be distilled without decomposition the hydrocarbon would have been formed by irradiation or more likely during distillation from a less stable photo product

Effect of Growth Substances on Growth and Fruiting of *Melanospora destruens*

IT has been shown[1] that a strain of the ascomycete *Melanospora destruens* which makes only negligible growth on a synthetic medium will grow vigorously and will produce perithecia on a similar medium to which a crude extract of lentils is added

Schopfer[2], Robbins and Kavanagh[3] and others have shown that the addition of vitamin B_1 to a synthetic medium will promote growth of *Phycomyces Blakesleeanus* and some other fungi

Wildiers[4] in 1901 showed that a growth substance which he called 'bios' was essential for the development of certain yeasts Later Eastcott[5] was able to split up bios into two parts one of which was identified as inositol Similarly Buston and Pramanik[6] fractionated the growth substance necessary for the development of *Nematospora gossypii* into an inositol fraction and an inositol free fraction Kogl and co workers have recently isolated a substance 'biotin with bios activity from egg yolk and have shown that while inositol biotin and aneurin (vitamin B_1) are necessary for maximum growth of some yeasts certain other fungi require only aneurin[7]

Through the kindness of Prof Kögl of Utrecht, I have been able to test the effect of biotin on *M destruens* A preparation of vitamin B_1 was also used

The strain of *Melanospora* used made negligible growth and produced no perithecia on a medium containing glucose potassium nitrate, magnesium sulphate and potassium dihydrogen phosphate The addition of various amounts of vitamin B_1 to this medium had no effect on the fungus When pure biotin methyl ester was added to the synthetic medium the *Melanospora* made good mycelial growth but produced no perithecia Growth and perithecial production were both good if both biotin and aneurin were added to the medium Thus these two growth substances have different effects on this fungus, biotin being necessary and sufficient for good vegetative growth and aneurin being necessary for the production of perithecia

The addition of inositol had no effect on either growth or fruiting

It is hoped to publish a fuller account of this work soon

Genetics of *Armadillidium vulgare* Latr

THERE are several varieties of the isopod *Armadillidium vulgare* Latr The colour of the commoner ones is either black or greyish A reddish brown variety also occurs I have obtained occasional specimens of this variety (var *rufobrunneus* Collinge[1]) from four different localities near Cambridge As can be seen from the accompanying table, this red colour appears to be a simple dominant to the commoner black colour (both the red male *A* and the red female *B* are heterozygous for this factor)

Brood	Parents	Progeny	
1 of 1937	Red male *A* × Red female *B*	27 red	13 black
1 of 1938	Red male *A* × Black female *C*	4 red	8 black
3 of 1938	Red male *A* × Black female *D*	5 red	11 black
of 1938	Black male *F* × Red female *B*	5 red	5 black

The apparent small size of the three broods in 1938 is due to the death of animals before they can be scored caused by faulty cultural methods

Brood 1 of 1937 was also scored for sex There were found 36 females but only one male (three animals died after having been examined for colour and before their sex was determined) The red female *B* thus appears to be thelygenic Vandel[2] has described in some detail the occurrence of amphogenic and monogenic (both arrhenogenic and thelygenic) females in another terrestrial isopod, *Trichoniscus provisorius* Racovitza The apparently normal 3 1 segregation for colour in this brood would not be expected if this brood were a parthenogenetic one such as are known to occur in triploid *Trichoniscus elisabethae* Herold (Vandel[3])

The exceptional male in Brood 1 of 1938 was of the black type with a pattern of yellow markings (var *variegatus* Lereb , see Collinge[4]) Such a variety appears, from collections and also from observations on the segregations in amphogenic broods to be normally a sex limited character found only in females Most males are entirely black in colour (var *plumbeus* Lereb , see Collinge[4]) All the red and black females in this brood also had the pattern of yellow markings

Work on the genetics of the different varieties of this woodlice is being continued, and it is also proposed to investigate the genetics of the amphogenic and monogenic types of females Such work must be slow since only one brood per year is obtained

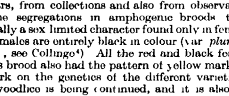
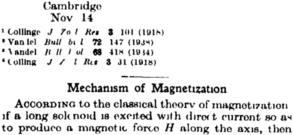
Mechanism of Magnetization

ACCORDING to the classical theory of magnetization if a long solenoid is excited with direct current so as to produce a magnetic force *H* along the axis, then if a long steel rod is placed axially in the solenoid the magnetizing force at the central part of the rod will be *H* and will be uniform over the cross section of the rod The following experimental results, however, indicate that this conception is incorrect





A solid drawn steel tube 24 in long, ¾ in outside diameter and ⅝ in inside diameter was arranged axially and centrally in a magnetizing solenoid about 4 ft 9 in long and about 4½ in internal diameter A search coil wound on a fibre rod support was arranged inside the steel tube midway between the two ends the general arrangement being as shown in the diagram The magnetic force inside the tube was then measured ballistically and the results are shown by the full line curve, which has been plotted as a function of the exciting current of the solenoid The steel tube was then removed whilst the search coil remained in position centrally in the solenoid The magnetic force was then measured ballistically and the values so obtained are shown by the broken straight line in the graph

It appears therefore that, for a given excitation, the magnetic force *H* inside the tube may be only about one half the value which is obtained when the steel tube is removed

These investigations are being extended by using a nest of tubes arranged with an annular space between every two consecutive tubes so that the magnetic force may be measured in each of the annular spaces

Friction of Clean Metals and the Influence of Surface Films

WHEN a metal is cleaned in air the surface will still be covered with a relatively thick layer of oxide and other adsorbed impurities Friction measurements are usually made with metals coated in this way, and if a lubricant is added, it is superimposed on the surface films already present Recent experiments[1] show that an intermittent clutching and breaking away of the surfaces takes place during sliding The results suggest that local adhesions may occur at the points of metallic contact and that the sliding friction may be due to the making and breaking of these welded junctions The molecular field of force at the surface of a solid is profoundly modified by the presence of an adsorbed layer so that, if this view is correct we should expect the surface film to have a large influence on the friction

It is a matter of considerable experimental difficulty to remove the last traces of adsorbed film from a metal surface, and few attempts to measure the kinetic friction of naked metals have been made Jacob[2], and Shaw and Leavey[3] found that when metal surfaces were partially cleaned in a vacuum the *static* friction showed an increase Holm and Kirschstein[4] showed that the adhesion between metals which had been heated in a vacuum was high On the other hand, Poschl[5] states that when surfaces are cleaned in a good vacuum the sliding friction between the surfaces becomes vanishingly small We have measured the *kinetic* friction between various metal surfaces which have been cleaned by prolonged heating, in a high vacuum, to a temperature near the volatilization point Within the limits of experimental accuracy, the friction was independent of the sliding speed, and in every case the removal of the surface films caused a very large increase in the friction The coefficient of kinetic friction between outgassed nickel and tungsten surfaces, for example, was $\mu = 6$, which *is nearly twenty times greater than* the friction of these metals when cleaned in the ordinary way

These observations lend strong support to the view that local adhesion between metals may occur Under normal conditions, when the metals are exposed to the air, the presence of adsorbed films will reduce the field of force at the surface When this film is removed, the strength of the field is increased, the metals are able to approach more closely, and the molecular interaction and adhesion are very much greater

The effect of adding gases and vapours to the outgassed metals was interesting Hydrogen and nitrogen had very little influence the friction remained at its high value even after prolonged standing The admission of a trace of oxygen water vapour or caproic acid vapour all produced an immediate fall This suggests that the presence of a primary film is capable of reducing the friction between the metals In most cases however this initial rapid fall was comparatively small and the friction continued to decrease with time It was not until thicker films were built up on the surface that the friction fell to values near those observed under normal conditions of measurement In the case of copper, for example it was necessary to form a visible oxide film before the friction fell to μ 0 6 Caproic acid vapour behaved in a similar way After the small initial rapid drop in the friction there was little further change until the surface was allowed to stand for some time in the vapour at its saturation pressure so that condensation could build up polymolecular layers of the fatty acid The friction then fell to a low value comparable with that observed under boundary lubrication conditions (μ – c 0 1)

The view was originally put forward by Hardy[6] that under boundary lubrication conditions the solids were separated only by a unimolecular film adsorbed on each surface and that the *static* friction was due to the interaction of these two adsorbed layers Other experiments[7] have shown that the *kinetic* friction under boundary lubrication conditions cannot be regarded as a purely surface phenomenon It is much more complicated and the effects extend to a considerable depth beneath the surface of the solid These observations support this view and suggest that the primary film is not enough and that a layer of the substance several molecules in thickness must be present before it can function as an effective boundary lubricant for moving surfaces

Verses about Buckland

IN view of the interest recently displayed in an Elegy, intended for Professor Buckland (NATURE Oct 8, p 673, and Oct 22, p 758), it may be appropriate to record Buckland s own comment upon it in a letter which he wrote to Miss Jane Talbot at Penrice Castle in Gower on December 11, 1820 Buckland had just returned from a long Continental trip which, he said, had been less adventurous in the line of imprisonments and banditti than the last, but had not been lacking in curious incidents He then went on 'In contemplation of the possibility of my remaining underground upon the Continent for ever I found upon my return that Mr Whateley of Oriel had composed for me an elegy which I am happy to have it in my power to forward you a copy The copy which follows in his own handwriting shows that the printed versions in Mrs Gordon s Life and Correspondence of William Buckland and in NATURE of October 8 contain a few copyists errors

There was also printed in The Life of Buckland a rhyming account of one of his lectures, said to have been delivered early in 1822 The lines were, however, written earlier than this, as they are mentioned in a letter which Buckland wrote to Lady Mary Cole also of Penrice on October 29, 1819 He was writing from Axminster and said I received last week a poetical epistle from my friend Mr Shuttleworth containing one of my lectures done into rhyme It is extremely neat and full of humour and will be highly entertaining to you

Part of the epistle is printed in The Life of Buckland , and it describes in rhyme how the tutors and undergraduates sat beneath Ashmole s ample dome while the inventive Master discoursed upon the history of the earth and the life it had supported in past ages This part which is omitted from Mrs Gordon s book is as follows

Allow me now that map of mine to show—
Tis Glostershire ten thousand years ago—

It being the object of the versifier to produce at present merely a specimen of his intended work he has omitted the following fifty verses exclusively geological concluding with

Those Bones I brought from Germany myself
You ll find fresh specimens on yonder shelf,

and also a digression of 2 300 lines of which the concluding couplet is

So curl the tails of puppies and of hogs
From left to right the pigs from right to left the Dogs

and also for the same reason the subsequent and still more digressive digression which is terminated by the following admirable reflexion—the whole passage consisting of 5 700 fresh lines

And not wild but *tame* cats only teaze their prey

The concluding couplet which is given without any alteration from the mouth of the learned Lecturer is here subjoined solely because it serves as an additional proof if such were wanting of the close connexion which subsists between geological speculations and not the ideas only but also the language of complete poetry It will be observed that tho intended only as a common sentence of adjournment it has all the fluency and grace of the most perfect rhythm and of its own accord glides into sense and hitches in a rhyme

Of this enough—on Secondary Rock
To morrow Gentlemen—at 2 o clock

Buckland derived considerable pleasure from the verses which he inspired and in a letter to Lady Mary Cole he wrote I believe few ladies have given origin to more poetry than my bag and hammer I enclose you copies of one or two by Mr Duncan and Mr Conybeare, and you that have seen my rooms will judge of the accuracy of the description of them ' The lines by Duncan are those on the Comforts of a Professor s Rooms in Oxford , printed in The Life of Buckland (p 9), while Conybeare s effusion is as follows

ODE TO A PROFESSOR'S HAMMER

Hail to the hammer of Science profound
Flint Stone and Rock
Quail at its shock
And their fragments fly as the sparks around

Beneath the storm of its thundering blows,
Rending and opening and staggering and reeling
Mountains reluctant their story disclose,
The secrets of Millions of Ages revealing
The fossil dead that so long have slept
And soon world after world into ruin swept
Start at the sound
Of its fearful rebound

Though fathoms deep in adamantine fold
The solid Rocks their fast bound corpses hold
Though every age— and thousands since have past
Hath made that sepulchre more deep, more fast
Yields the firm Rock and through the rifted stones
Pours the strange light on the long shrouded bones

A Sun—not that whose earlier Ray
Illumined their primæval lay
But younger many a generation—
Their sun's great Grandson at the Last
Shines on each antiquated beast
And now first wakes their slumbering nation

Each old crocodile grins with vast amaze
While rousing him from his marble hearse
As a world so new and so strange he surveys
And doubtless he thinks that since his younger days
Things are strikingly changed for the Worse

The manuscripts upon which the foregoing notes are based are in the Department of Geology at the National Museum of Wales, having been presented to that Institution by Dr Mervyn Gordon

Binocular Vision

The ability to see stereoscopic pictures without a stereoscope referred to by Mr G R R Bray in NATURE of Nov 26 p 959, is if not common, at least fairly easy to acquire I have been able to view such pictures with naked eyesight for many years past If one places a pair of stereoscopic pictures at the normal distance from the eyes for comfortable vision and then directs one's gaze just over the top of the pictures at some more distant object two images of each of the pictures will immediately appear By a little practice the right hand image of the left picture and the left hand image of the right picture can be brought into coincidence the coincidence occurring rather suddenly in the end and as it were *engaging* in that position This sudden coalescence is I presume due to the eyes refocusing at normal distance each on its own picture When this has occurred the equilibrium is fairly stable

I have sometimes thought that it might be possible to teach this little accomplishment to an audience, and then to exhibit stereoscopic pictures in this way on the screen

T S PATTERSON

Organic Chemistry Department,
University of Glasgow

Points from Foregoing Letters

PHOTOGRAPHS of spectra of blue auroras at a height of 250-650 km taken at Oslo, Norway, on September 15 last are submitted by Prof C Stormer By comparison with the lower (92 km high) yellow green curtains of the auroras in the earth's shadow, the spectra of the blue auroras show that the relative intensity of the lines 6300, 4278 and 3914 A has increased considerably (6 – 8 times) as compared with the line 5577 A

Sir Joseph Larmor directs attention to the work of Ives and Stilwell, who have measured the second order change in the free periods of the hydrogen atoms in the canal rays flying transverse to the line of sight, thus verifying the theoretical frequency factor $(1 - v^2/c^2)^{1/2}$, he also discusses the second order effects that might be expected from the influence of gravitation upon light

The unshrinkable finish imparted to wool by various processes depends on the formation of a gelatinous degradation product of keratin, on or under the scale structure of the fibres, according to Dr J B Speakman, B Nilsson and G H Elliott, they state that this may be accomplished by means of any reagent (such as chlorine) which is capable of breaking down the disulphide bonds

Prof L Califano and D Kertesz find that the 'activating effect' of *o* diphenol upon the action of 'tyrosinase' extracted from *Sepia* is merely a reduction of the induction period, they consider that the assumption of the existence of a tyrosinase enzyme to explain the tyrosine oxidation is unnecessary

Dr E Bergmann and Y Hirshberg describe the changes brought about in Δ^4 cholestenone by ultra violet irradiation Besides resinous material, a bimolecular reaction product, $C_{42}H_{62}O$, is formed by loss of six carbon atoms and dimerization

Dr Lilian E Hawker finds that in order to grow the fungus *Melanospora destruens* on a synthetic medium composed of glucose, potassium nitrate, magnesium sulphate and potassium dihydrogen phosphate it is necessary to add biotin (a growth substance obtained from egg yolk) for good vegetative growth and aneurin (vitamin B) for the production of perithecia

H W Howard reports that in the wood louse *Armadillidium vulgare* Latr a red variety behaves as a simple dominant to the commoner black form In a brood of 37 which showed a 3 1 segregation there were 36 females and only one male

Measurements made by Dr T F Wall of the magnetic force at the axis of a long solenoid, (i) when a steel tube is arranged axially in the solenoid and (ii) when the steel tube is removed, indicate that one aspect of the classical theory of magnetization is incorrect

Dr F P Bowden and T P Hughes find that when the adsorbed films normally present on metals are removed the kinetic friction between them is very great and may be twenty times that usually observed A layer several molecules in thickness must be present before a substance can function as an effective boundary' lubricant for moving surfaces

Modern Maya Houses of Central America

AN elaborate study of the modern Mayan house of Central America has been made by Mr Robert Wauchope (Carnegie Inst Washington, D C , *Pub* No 502, 1938 Pp 181 with 37 pl) with special reference to its bearing on the archæological problem of the construction and arrangement of the dwelling house of the ancient Mayas Archæological excavation, owing to the character of the structure reveals little evidence, except of the substructures Attention was directed especially to the manner in which the modern house falls to pieces The close resemblance between the ancient house as shown in the frescoes and the modern house has been pointed out frequently Present day Maya villages are probably assembled more systematically than those of ancient times, when they were either located at haphazard or clustered in the neighbourhood of important buildings There is evidence to suggest that the present day practice was followed according to which an owner builds on houses additional to his own to accommodate tenants for stipulated service At present the isolated house is rare in Yucatan and Campeche, but common in Guatemala The siting of a house is determined by the condition of the site poor drainage, outcrops of rock or rough surface being avoided The floor is composed of the ground, levelled and improved by marl and earth A low platform or substructure is erected to support the house Some are provided with terraces Most modern dwellings are of the single room type but there are also some with an enclosed room at the back and an open porch front or with three or four rooms facing on porches and located side by side under a single roof Houses in the Maya area are either apsidal flat sided with rounded corners rectangular, square or rounded in ground plan The same plan in building is followed throughout The mainposts of the house are well inside the line of the walls and stand independently of the rest of the house framing Cross beams rest on the forks of the mainposts and carry the plates The chief weakness of the Guatemalan house is in its long axis The main types of roof are the hip roof and the gable roof Practically all are quarter pitch The use of adobe brick differentiates the houses of Honduras, Guatemala and highland Mexico from those of Yucatan, where rubble masonry wet or dry, is in use Windows are rare

Decarboxylation by the Typhoid Bacillus

MADELEINE LACHAMPT (*Thèse de Paris*, 1938 No 661) has investigated the action of *Bact typhosum* on the two amino acids histidine and tyrosine, which are respectively capable of producing histamine and tyramine by decarbolization The decarbolization of histidine which gives rise to histamine takes place as the result of the action of various micro organisms such as *B aminophilus* some strains of *Bact coli* *Bact lactis aerogenes* and Friedlander s bacillus, and can also be produced by *Bact typhosum* in a culture medium containing a source of carbon and nitrogen distinct from histidine Decarbolization of tyrosine which gives rise to tyramine is produced by *B aminophilus*, *Proteus vulgaris* *Bact lactis aerogenes* and *Bact coli*, and can also be produced by *Bact typhosum* in a medium containing a source of carbon and nitrogen distinct from tyrosine

Japanese Martin Fly

THE black chinned martin *Delichon urbica dasypus* is infected by a house fly, *Stenopteryx nipponica* (Fam Hippoboscidæ) regarding the biology of which nothing has so far been published The species described by K Kishida in 1931, seems to be limited to the black chinned martin, for no specimen was found in the nests of swallows or other birds, although the nests of the martin were heavily infested and a few individuals were found attached to the birds themselves Kaoru Huziematu now describes the life history in detail from observations made at Tubame Hotspring Japan (*Sci Rep Tôhoku Imp Univ* , Ser 4 13, 59 , 1938) Mating generally takes place while the flies are in the nest, and the egg hatches in the uterus of the female insect, where by contraction and dilation of a tongue like organ the larva feeds upon glandular secretions After three instars, the full grown larva now covered with a more or less chitinized skin is deposited in the martin s nest The pupal period in the summer is 23 days but in the autumn after the emigration of the martins puparia were found in the nests and from these the adults do not emerge until the following spring In this respect the pupal life history resembles the stages of Sommerpuppe and Winter puppe described by Hardenberg in *Stenopteryx hirundinis*, the corresponding parasite of the European house martin

A New Method of Development in Tufted Mosses

A CURIOUS problem in the genus *Plagiochila* has been the explanation of the small plantules known as *P Stableri* which occur in the vicinity of *P. asplenioides* Douin (*Ann Bryologici* **11** , 1938) has now shown that *P asplenioides* develops axillary branch initials the upper developing into normal branches whilst the lower swell at the base and become detached The latter fall on to lower leaves soil and neighbouring mosses and there develop rhizoids and behave as small epiphytic or free living plantules with the characteristics of *P Stableri* Douin considers the development of similar branch initials to be responsible for the multiplication of the erect stems of many tufted mosses These are figured for *Funaria hygrometrica* In *Bryum argenteum* spore production is not sufficiently common to account for the rapid spread and increase in size of tufts, and yet neighbouring stems of the tuft show no connexion with one another Such deciduous branch initials would offer a satisfactory explanation of the prolific multiplication in such cases

Epicentres of Recent Earthquakes

PROVISIONAL epicentres of three recent earthquakes have been determined by the United States Coast and Geodetic Survey in co operation with Science Service and the Jesuit Seismological Association from instrumental records obtained at U S Observatories (*a*) 1938 Nov 5 d 8 h 43 3 m G C T , epicentre lat 38° N , long 141° E There was a probable after shock from the same epicentre on Nov 5 d 10 h 50 2 m G C T These were recorded by twenty three stations (*b*) 1938 Nov 6 d 8 h 53 m 57 s G C T , epicentre lat 36° N , long 144° E There was apparently an aftershock from the same epicentre on

Nov 6 d 21 h 38 7 m G C T These were recorded by twenty stations (c) 1938, Nov 10 d 20 h 18 7 m G C T , epicentre lat 56° N , long 159° W This was recorded by twenty three stations The first and second of these were off the north east coast of the main island of Japan and the third was immediately to the south of the Alaska Peninsula All have been mentioned previously in NATURE

Seismological Data and Volcanicity

E M ANDERSON applies seismological data to the magma problem in a paper delivered at the section of volcanology, International Union of Geodesy and Geophysics, on September 22 1936 (*Bull volcanologique*, 3 Series 2, Naples, 1938) The author is concerned to make out a case for a system of surface layers on the earth such as will be consistent with the petrological make up of such layers, which he considers necessary for the explanation of past and present volcanic activity The data used are in part derived from the study of actual individual earthquakes, and partly obtained from studies of the physical properties of rocks The layer which transmits the P_g and S_g waves is considered to be 10 13 km thick and to be petrologically similar to the Scottish Lewisian gneiss Two sets of P^* and S^* waves are considered possible necessitating a division of the intermediate layer into an upper one of tholeitic basalt similar to the Whin Sill, and a lower one consisting of olivine basalt The two together are considered to be about 25 km thick The author admits that the subdivision is still in the hypothetical stage Sparks s paper has been further discussed by Stoneley (NATURE November 5 p 840) The underlying material down to a depth of 480 km , which transmits the P_n and S_n pulses, is suggested to consist of dunite, peridotite or eclogite

Oxides of Bromine

IN 1937, Schwarz and Schmeisser reported the discovery of bromine dioxide BrO_2 which they prepared by passing the silent electric discharge between aluminium electrodes through a mixture of bromine and oxygen in the proportion of one part to five The oxide was described as an egg yellow solid It has now been further investigated by Schwarz and Wiele (*Naturwiss* , 26 742, 1938) When heated not only does it decompose to some extent into its elements but also it gives rise to a white compound apparently a higher oxide of bromine either Br_2O_7 or Br_2O_8 and a dark brown oxide Br_2O (about 20 per cent of the yield) The latter was isolated in the pure form It is no doubt identical with the compound obtained by Brenschede and Schumacher in 1936 but these workers obtained it with excess of bromine in carbon tetrachloride solution, and determined its formula by investigation of its absorption spectrum and from lowering of the freezing point The substance now obtained in the pure form dissolves in carbon tetrachloride with a strong green colour Molecular weight determinations in solution indicate that the substance has the simple formula Br_2O When allowed to act on carbon tetrachloride for a considerable time, the latter is oxidized to carbonyl chloride It reacts smoothly with sodium hydroxide forming sodium hypobromite Bromine monoxide has a powerful odour, reminiscent of hypochlorous acid It is stable below – 40°, but gradually decomposes above this temperature The rate of decomposition is not great, however, even at 0°

No-Loss Dimmers for Small Cinemas

IN the *Siemens Review* (14, (3), 146 , 1938) published in Berlin, a description is given of new apparatus for the gradual dimming of the lighting on the stage in cinemas, concert halls etc The Siemens dimmer has the great advantage over the early resistance dimmers that the dimming of the lighting is practically unaccompanied by losses At the last Leipzig Spring Fair a few of the smaller no loss dimmers were exhibited of the types employed in amateur theatricals, small cinematic exhibitions, etc There was shown a motor driven circular dimmer with one regulating arm, and a two arm dimmer with sheaves for hand operation from a control stand The rated load for one arm at 220 volts is up to 4 400 watts and for two arms it goes up to 5 500 watts Within these limits any number of lamps can be connected without in any way affecting the degree of the efficiency of the dimming For larger installations comprising more than two circuits, it is customary to use Siemens Bordoni dimmers If the supply is single phase sixteen circuits can be connected and if three phase fifty four circuits The Bordoni dimmer shown at the Fair was arranged for four circuits and equipped with four regulating slides, with corresponding driving frame The two circular dimmers were connected up for demonstration purposes to a part of the stand lighting the corresponding reduction in the current consumption being rendered visible to the visitors by the readings on a wattmeter

Wave Geometry

EARLIER investigations on this subject by a group of workers at the Hiroshima University Japan have already been mentioned in NATURE (Dec 21 1935, and May 22 1937) Previous notices dealt with fifteen papers Since that time no fewer than eighteen more have appeared The first twenty five papers have now been reprinted and published under the title of Collected Papers on Wave Geometry (Tokyo Iyubun Kan, 1938) One of the most interesting is No 22 by K Morinaga The Hydrogen Atom in Terms of Wave Geometry At first sight, the work appears to be quite different from the usual relativity of quantum treatment but the final results agree closely with those of Schwarzschild, de Sitter, Schrodinger, and Dirac However, there is one difference in the physical interpretation Although the ψ of the wave geometry equation has the same mathematical properties as that of the same symbol in Dirac s work, the former is associated mainly with the nucleus but the latter with the electron Paper 24, by T Iwatsuki Y Mimura and K Morinaga, and Paper 25, by T Sibata deal with Born s new field theory In the original form of this theory, various difficulties arise, and to deal with these what appear to be rather arbitrary assumptions are made It is shown that Born s theory can be regarded as a form of wave geometry, and that in consequence there is a natural and obvious method of overcoming the difficulties referred to As for the later papers, several of interest are contained in the *Journal of Science of the Hiroshima University* (8 , 1938) In Paper 31, K Itimaru shows that the red shift of the spectral lines of the nebulæ and the Hubble velocity distance relation can be deduced from wave geometry The wave geometry form of cosmological theory is nearly the same as de Sitter s, with one fundamental difference It is consistent with the existence of finite concentrations of matter, and so accords with the actual universe

Annual Meeting of the Royal Society

Awards of Medals*

Copley Medal: Prof. Niels Bohr, For. Mem. R.S.

Prof. N. Bohr has been for many years the recognized leader of theoretical atomic physics. His early work in 1913 provided the connecting link between Planck's conception of quanta and Rutherford's of the nucleus, and made it possible for the first time to constitute a consistent theory of spectroscopy. The development of this theory owes nearly as much to Bohr as did its inception. Among other things, he invented the principle of correspondence, according to which quantum phenomena pass over into the classical as a limiting case, following certain definite rules which Bohr laid down. This principle was of the greatest importance in the early days of the theory.

Besides providing a rational explanation of atomic spectra, Bohr's theory made it possible to give a satisfactory explanation of the structure of atoms and in particular to explain the changes in properties which occur as we go from one element to the next in Mendeléeff's Periodic Table. In doing so it provided an explanation of the shells of electrons proposed by J. J. Thomson. In the development of this theory Bohr's mathematical ingenuity and his application of the theory of perturbation played a large part.

When the principles of wave mechanics were initiated by de Broglie and Heisenberg, the latter of whom was a pupil of Bohr's, Bohr took an important part in the development of the new ideas and in transforming atomic theory to fit them. The view which is held at the present day of the relationship between waves and particles is very largely due to Bohr.

In the last few years Bohr has transformed the ideas held as to the structure of the nucleus by pointing out the intimate association of the particles which comprise it, and the necessity for treating them as part of a closely knit system more like a liquid than a gas. This fundamental idea has already had far reaching effects, and is the basis of almost all present work.

Although his published papers are of supreme importance, it is probable that Bohr's greatest contribution to physics lies in the influence which he has exerted over an enormous proportion of the leading physicists of the world.

Rumford Medal: Prof. R. W. Wood, For. Mem. R.S.

The study of physical optics owes much to Prof. Wood, who has been one of the leading experimenters in this field for the past forty years. Before the advent of Bohr's quantum theory, when our knowledge of the structure of atoms and molecules was very meagre, Wood had discovered the line and continuous absorption of sodium vapour, the phenomenon of resonance radiation of gases and vapours, and the quenching of this radiation by foreign gases. These discoveries opened up rich fields of research and were of the greatest value to later workers in laying the foundations of the theory of atomic and molecular spectra.

The elucidation of the phenomenon of resonance radiation demanded the utmost experimental skill and resource. Nothing less powerful than an improvised 40 ft. focus spectrograph sufficed for his work on the remarkable resonance spectra of molecules. In addition to his researches on the resonance radiation of metallic and other vapours, Wood investigated their magnetic rotation and dispersion. More recent but belonging to the same domain of experiment are the very interesting discoveries of Wood and Ellett on the magneto optics of resonance radiation.

Wood's mastery of technique is universally acknowledged. He has introduced many ingenious and striking devices to experimental method. These are too numerous to catalogue here, but special mention must be made of his method of the production of atomic hydrogen and his observations on the spontaneous incandescence of substances in atomic hydrogen which led to the invention of the atomic hydrogen welding torch by Langmuir, his very efficient and now widely used method of observing Raman spectra, his échelette grating which has proved to be the grating *par excellence* for the investigation of the near and far infra red, and his pioneer use of light filters in ultra violet and infra red photography.

A Royal Medal: Dr. F. W. Aston, F.R.S.

Few cases are known to science in which an important development has remained so much in one man's hands as has the study of isotopes, by means of the mass spectrograph, in those of Dr. Aston. Aston's attention was directed to isotopes by his work as assistant to Sir J. J. Thomson when the latter was working on the analysis of positive rays by the parabola method. The results for neon suggested very clearly that this element contained atoms of weight 20 and 22, but other explanations were conceivable.

After the Great War, by means of his mass spectrograph Aston showed that the lighter constituent of neon had a mass less than corresponded to the density of the gas as a whole, which was therefore a mixture. But the results went much further, and Aston found that not neon alone but also the majority of elements consisted of mixture of isotopes, in the sense already established by Soddy and others for certain products of radioactivity. This discovery profoundly altered men's views as to the nature of the ordinary chemical elements. For one thing, atomic weights as ordinarily determined were seen to be merely weighted means and not fundamental constants. By various modifications of this method Aston was able to extend his experiments to cover the great majority of the known elements, and to establish the existence of hundreds of isotopes. In addition, he was able to show that, with the exception of hydrogen, all the isotopes had nearly integral atomic weights taking oxygen as 16 This result was of great importance in connexion with Rutherford's theory of the nucleus

---

*From the remarks made by Sir William Bragg, Pres. R.S., in making the presentations.

The later developments of Aston's work are concerned mainly with the small deviations from this whole number law Since on the theory of relativity mass and energy are equivalent the mass of a nucleus is a measure of its internal energy and the small divergences from whole numbers give the energy with which the constituent particles are bound together Using an improved mass spectrograph capable of an accuracy of 1 in 20 000 Aston has determined this binding energy with considerable accuracy, at least for the lighter elements

By determining photometrically the proportions of the isotopes Aston has been able to calculate 'chemical atomic weights which in some cases have corrected those found by the older methods Thus both in chemistry and in physics Aston's work has been of outstanding value

A Royal Medal Prof R A Fisher, F R S

Prof R A Fisher's contributions, both to the development of the logical theory of statistical methods and to the invention of efficient tools for the use of the experimental worker have been of outstanding importance Before Fisher entered the field (in 1912), the work of Galton Pearson and their immediate pupils had widely extended the connotation of statistical methods particularly in biological research Useful descriptive methods had been invented, and reasonably adequate tests of sampling errors when samples were large (say, a hundred or more observations) were made available As a result there was an enormous increase in the number of workers who applied quantitative methods to biological, medical and sociological problems

It may be said that in freeing the statistical methods of weaknesses obvious a quarter of a century ago, Fisher has been one of the chief contributors to the improvement of the logical basis of statistical methodology He has been the most important contributor both to the theory and practice of small sample analysis, and to the armamentarium of statistical tools for biological and technological research His own practical contributions to the study of genetics have been neither few nor unimportant but the scope of his work has covered a much wider field of scientific research concerning both the physical and biological sides

Davy Medal Prof G Barger, F R S

Prof G Barger's two most important contributions to knowledge are linked together namely, his work on the alkaloids of ergot and on the sympathomimetic amines After his isolation (with Carr) of the alkaloid ergotoxine, to which the effect of ergot on the cock's comb is due, he showed that the pressor bases from putrid meat were the products of decarboxylation of amino acids, and included *p* hydroxyphenylethylamine, derived in this way from tyrosine He worked out methods for the synthesis of *p* hydroxyphenylethylamine and allied compounds, and proved that this compound and also histamine, the product of decarboxylation of histidine, occurred in extracts of ergot

One of the earliest systematic investigations of the relation between chemical constitution and pharmacological properties was the work which Barger carried out in collaboration with Dale on the sympathomimetic amines of the phenylethylamine class He has made considerable contributions to our knowledge of the constitution of many alkaloids and also of many naturally occurring derivatives of amino acids Special mention may be made of his work carried out jointly with Harington, on the constitution and synthesis of thyroxine

Darwin Medal Prof F O Bower, F R S

Prof F O Bower's main contributions to botany have been the intensive study of the morphology and affinities of ferns and allied plants A series of papers on the development of spore bearing organs in the Pteridophyta is a contribution to phylogeny of great importance In his book Origin of a Land Flora (1908) Bower discussed evolutionary problems with special reference to the Bryophyta and Pteridophyta, twenty six years later he dealt with the same problem in Primitive Land Plants His three volumes on ferns (1923–28) are a classic work on the affinities of members of this group and a most valuable source of information In 1930 he discussed Size and Form in Plants Prof Bower has consistently devoted himself to a branch of botanical science in which he has long been regarded as a leading authority By his own researches and the judicial examination of recorded facts he has thrown light on the natural affinities of certain groups of plants

Hughes Medal Dr J D Cockcroft, F R S, and Dr E T S Walton

The discovery by Dr J D Cockcroft and Dr E T S Walton that the transmutation of elements can be effected by means of artificially accelerated particles has opened up a new line of work of outstanding interest and importance In previous experiments, initiated by Rutherford so long ago as 1919, the transmutation of several elements had been produced by bombarding them with the α particles from the natural radioactive substances In this early work it was thought that bombarding particles of very great energy were required to disrupt atomic nuclei The development of quantum mechanical ideas to nuclear problems made it possible for the first time to see how charged particles of low energy could penetrate into an atomic nucleus, and, moreover, enabled calculations to be made of the probability of penetration

It was on the basis of such calculations that Cockcroft and Walton came to the conclusion that protons accelerated by moderate potentials, of the order of a few hundred kilovolts, should be able to effect the disintegration of the lighter elements. During 1930 attempts were made to disintegrate lithium by bombardment with protons using accelerating voltages up to 300,000 v The results were at first negative, but continued experiment, in which the apparatus was re designed to give voltages up to 600 kv, was in 1932 rewarded with the successful disintegration of lithium by bombardment with protons Thus for the first time an atomic transmutation was effected by means entirely under the experimenter's control These experiments of Cockcroft and Walton gave a tremendous impetus to investigations in nuclear physics

Indian Archæological Investigation, Teaching, and Research*

THE mystery and fascination of Central Asia have been felt by three generations of travellers and scholars, and to day we are blinded by treasures which a series of great excavations has given to the museums of Europe and Asia. It is in the museums and weighty reports of excavations that the historian must quarry for the raw material of history. The history of Central Asia has yet to be written and for the most part we have to be content with brief and disconnected fragments forming a background on which we must try to place the pieces of archæological evidence. The present expedition was undertaken in part with the object of directing attention to these problems in part in the hope of providing a few fragments of evidence bearing on the great problem that of chronology in the study of the Buddhist art of Gandhara, the country which lay between the Indus and the Hindu Kush. The chronological scheme of Foucher who wrote what still ranks as the standard work on Gandharan art convenient and coherent as it is is purely stylistic, and does not meet the requirements of the archæologist and historian as had been demonstrated by the archæological investigations at Hadda of the French delegation which has been at work in Afghanistan since 1922. Evidence of the influence of Gandharan art has come from various central Asian sources extending so far as Turfan in Chinese Turkestan, but there is one blank in the record Bactria and the Oxus territory.

The present expedition beyond the Indian frontier spent the summer months of 1938 excavating in the valley of Swat and later on the invitation of the director of the French delegation and with the permission and assistance of the Afghan Government in an archæological reconnaissance of the archæologically unexplored territory in the north of Afghanistan, covering a distance of two thousand miles.

In the Swat valley Barikot was made the first camping site of the expedition in order to excavate some of the monastic and domestic sites in the three side valleys which converge at this point. In the course of the two months which were spent here, a complete survey was made of all the Buddhist ruins and a map was prepared showing not only the remains of stupas monasteries and fortresses but also of those of their dependent villages and terraced cultivations with the view of determining the areas of settlement and the relations between domestic remains and areas of cultivation in fact, to see what this small area looked like in Buddhist times. It was also hoped to determine the relation between specific pieces of sculpture and such domestic objects as might help, because of their appearance elsewhere in dateable contexts, to establish a chronology of Gandharan art.

Khanjar Khote a typical monastic site, and one of a number excavated, consisted of a main courtyard in which a stupa stands, surrounded by small stupas, following no fixed plan. They were evidently built by different donors and probably at different times. Behind is another courtyard and cells for monks some of which probably became niches in which a Buddha was set up aligned along a road and at higher levels built in the hillside. The harvest from the small stupas was not rich—a number of pieces of blue schist showing scenes from Buddha's life in relief two or three plaster heads, carved bases of model stupas and innumerable pieces of broken decoration. Amluk a solitary site on a mountain top was a more interesting place. Here the masonry was of unfamiliar pattern and the harvest richer. Hence came a 3 ft seated Buddha of Foucher's 'late variety'. The circumstances in which the sculptures were found suggests destruction by Mohammedan invaders rather then the slow decay of which Hiuen Tsiang speaks.

Two members of the party excavated an acropolis 120 ft high and covered with potsherds at Charbagh in Upper Swat but with disappointing results. Some terra cotta animal figures and one human torso may prove of value, but owing to the conservatism of the Indian potter it is probable that we shall never achieve an intelligible chronology or even classification of types of pottery such as the European archæologist is accustomed to use as his guide.

Until the plaster heads have been compared with those from Takht i Bahi and Hadda until seals pottery and iron objects have been studied and corroded coins have been cleaned and deciphered it cannot be said how much nearer this summer's work has brought us to an archæological as distinct from a stylistic chronology of Græco-Buddhist art or whether any contribution has been made to the solution of another problem—why such a virile hybrid art sprang up in a comparatively small area on the Indian frontier and spread to Afghanistan and Chinese Turkestan. The main type of the Swat Buddha, however, has been established. He is squat and expressionless with an Indian face. The Boddhisatva is not a saint but an Indian prince in Greek dress.

At the end of July two members of the party, the leader and one other left for Kabul and starting thence crossed the Hindu Kush into the Oxus plain where a large number of the mounds with which Bactria is covered were examined and measured. At Kunduz twenty five miles south of the Oxus there are a number of mounds and an impressive 'round castle, with mud walls more than a hundred feet high and half a mile in circumference. It may be one of the centres by which the Sassanid kings kept their precarious hold on Bactria. On one site here a find was made which may be of importance—carved bases of Greek columns which disprove the contention of M Foucher, that the Hellenistic cities of Bactria were built of mud and sun dried brick.

In the preparations for this expedition, although the keeper of the India Museum, London, and others were of the greatest assistance the lack of a centre for Indian archæological studies in London, it was stated, had proved a grave handicap. Unless such expeditions as this are to be nothing more than a flash in the pan, if British work in India is to have a long term programme, something more substantial is required than the occasional enterprise of one or two individuals There must be a permanent centre in London for teaching and research, which would be a base for such expeditions and for the study of the material they bring back It is obvious that the personnel of expeditions should not be recruited in haphazard fashion from persons with few qualifications There should be a team of specialists engaged in teaching and research who could be drawn upon for expedition work from time to time as occasion offered It is sad to think that at a time when India is much in our minds at a time when our relations with her have reached a turning point in history and she stands at the brink of a great experiment there should be no professional home in London for the study and appreciation of Indian history and culture Though there is still some doubt as to the function of a museum those who know what the present keeper has done for the India Museum a place where the student can now study each of its civilizations as a whole and in all its aspects would agree that if there is to be a centre for teaching and research and a base for future expeditions it can only be the India Museum

---

* Abstract of a lecture on The Results of the Recent Archæological Expedition to Swat and Afghanistan in Relation to the Present Position of Indian Studies in this Country by Evert Barger lecturer in medieval history in the University of Bristol delivered before the Royal Society of Arts on November 30.

A discussion followed the lecture (see p 1029)

The Future of Gaseous Fuel

THE town's gas industry is now well advanced into its second century of activity, although during the last half century it has from time to time been considered by observers as doomed to supersession sooner or later by other methods of using coal Such opinions based as they were on superficial knowledge, were always unwarranted, as revealed by the fact of steady growth of the use of gaseous fuel and the number of its applications This growth has accompanied an increase in the efficiency of appliances The present position and future of the industry have been the subject of several addresses in recent months

Some time ago, Mr E V Evans read a paper to the Royal Society of Arts on the importance of coal carbonization in the life of the nation emphasizing *the range and indispensability of its products* The modern tendency to avoid arduous and dirty tasks of domestic routine promotes the expansion of the use of gaseous fuel which need not be stored and lends itself to automatic control The same tendency is seen in many industrial heating operations in spite of systems of charging which often do not encourage the free use of gas It is only since 1920 that the sale of gas has been based on the heating value and even now freedom to base sales on a rational system of charging is not complete On this depends the expansion of use for large scale operations

Sir Harold Hartley, in his presidential address to the Society of British Gas Industries said that the strength and vitality of an industry depends on the way it uses the resources of science Research is 'the best insurance of its future he said and he referred to what the application of science has done to maintain and promote development of the use of gaseous fuel The range and extent of this was given in very specific terms in a recent address of Sir David Milne Watson to the Fuel Luncheon Club, when he said that his own company—the Gas Light and Coke Co incurs annually an expenditure exceeding £100,000 on its research activities In them all types of scientific skill are brought to bear on the problem of gas manufacture and purification and utilization including the handling of by products

Mr Evans looking to the future envisaged the possibility of producing gas without coke—something which a very large increase in the use of gaseous fuel might render urgently necessary Already the industry has initiated research on the gasification of coal under pressure The possibility of securing far reaching gasification and the production of large yields of methane and primary tars is already foreshadowed If the early promise already shown is followed by economic success the distribution of fuel in gaseous form will receive a great impetus While these developments are proceeding it will be interesting to watch the progress of the experiments made by the Soviet Union on the underground gasification of coal Following on experiments it is reported by the Russia Today Press Service that a commercial plant commenced operation in Gorlovka in 1937 Others are projected—one to supply Moscow and claims are made for the cheapness of the gas

H J H

University Events

CAMBRIDGE C B Davies of Trinity Hall has been appointed for the present academical year to the studentship offered by Imperial Chemical Industries Ltd

The degree of Master of Arts has been conferred upon Dr A J Bradley assistant director of research in crystallography

Sir Edward Mellanby secretary of the Medical Research Council has been appointed Rede lecturer for the year 1939

The following appointments in the Museum of Zoology have been made F R Parrington of Sidney Sussex College to be director, H B Cott of Selwyn College to be curator of vertebrates and Strickland curator J E Smith to be curator of invertebrates, Dr G C Varley of Sidney Sussex College, to be curator of insects Dr Varley has also been appointed University demonstrator in zoology

The British Electrical and Allied Industries Research Association and the Permanent Magnet Association have offered to make jointly a grant of £550 a year to the University for the purpose of supporting research on *magnetic materials* under the direction of Prof W L Bragg and the Iron and Steel Industrial Research Council has offered to the University a grant at the rate of £500 a year for research on the structure of alloys, to be carried out in the Cavendish Laboratory under the same direction In both cases, the grants will provide for the continuation of investigations which have been in progress for some time under Prof Bragg's direction, first at the University of Manchester and afterwards at the National Physical Laboratory

LONDON—The title of professor emeritus of embryology in the University has been conferred on Prof J P Hill, on his retirement from the University chair of embryology at University College, and that of professor emeritus of chemistry in the University on Prof Samuel Smiles on his retirement from the Daniell chair of chemistry at King's College

Science News a Century Ago

New or Rare Plants in Edinburgh

On December 10 1838, Robert Graham, professor of botany, sent to the *Edinburgh Philosophical Journal* a Description of several New or Rare Plants which have lately flowered in the Neighbourhood of Edinburgh The *Chorizema Dicksonii* he said, was raised by Dickson and Sons from seed sent from Swan River, Australia, the *Collinsia heterophylla*, the handsomest species of *Collinsia* yet known, was found by Nuttall on the Columbia and was raised at the experimental garden from seeds sent from America the *Eduardsia Macnabiana* had been cultivated in Edinburgh for some years but it was not known whence it came and the *Mirbelia augustifolia* though apparently a distinct species but without beauty, was raised from seed from New Holland

Littrow's Observations of Meteors

The *Athenæum* of December 15 1838 reprinted from the *Vienna Official Gazette* a note by Karl von Littrow on Falling Stars in August and November The phenomena said von Littrow, of an extraordinary abundance of falling stars, about the middle of November has been again observed this year On the 10th of November when we watched from eight in the evening till one in the morning, we counted about nine such stars in an hour On the 11th of November we counted about twenty in an hour On the 13th of November the sky suddenly cleared up an half an hour before midnight and remained perfectly serene till daybreak During those six hours we noted 1002 falling stars Von Littrow then went on to refer to the observations made in August

Karl Ludwig von Littrow (1811 77) was the son of Joseph Johann von Littrow (1781–1840) who from 1821 until his death was professor of astronomy and director of the observatory at Vienna In 1826–27 the latter erected an observatory in the middle of the city on the site of that founded by Father Maximilian Hell in 1753 Karl von Littrow became an assistant under his father in 1831, succeeded to the directorship in 1842 and it was during his period of office that in 1874–77 the modern observatory was built Newcomb in The Reminiscences of an Astronomer" tells how through colour blindness von Littrow had been led to wrong conclusions regarding alterations in the manuscript notes made by Father Hell of the transit of Venus of 1769

Brickmaking by Machinery

The *Mechanics Magazine* of December 15, 1838 contained a note on Jones's Machinery for Moulding Bricks The earth,' it said, in its descent, is forced into the moulds by great pressure as they pass under the Pug Mill and is delivered therefrom in perfect bricks upon pallet boards ready to be removed, the whole of which is done by the horse attached in the usual way to the Pug Mill producing from 1,000 to 2,000 bricks an hour The earth also being moulded with only one half the usual quantity of water will take considerably less time to dry A machine was at work last week on three successive days at Messrs Webb's brickfield, near Ball's Pond Church, Islington, and performed the work admirably "

Science and Learning in Distress

In the early summer of 1933 the Academic Assistance Council was founded under the presidency of Lord Rutherford and with the active support of many distinguished men of science and other scholars to find places in the fabric of world science and world scholarship for men and women driven from their countries and their work for racial religious or political reasons Such persecution was not new even in the very recent past it had happened again and again in Russia and was still happening but the scale of its application in Germany and the distinction of its victims demanded immediate help The Academic Assistance Council had no partisan political or national bias Indiscriminate relief was to be no part of its work Its purpose was to act as a link between the scientific workers and other scholars displaced and the universities and research institutions of the world so that their exceptional abilities exceptionally trained—to quote the noble declaration of the Council's founders—should not be lost

It was hoped that the emergency would pass but as the years went on intolerance and persecution grew no end was in sight The Academic Assistance Council took permanent shape therefore as the Society for the Protection of Science and Learning its wider purpose was now to act as a clearing house of information and advice to exiled scholars and to persons institutions and departments desiring to help them its narrower purpose—within the limits of its resources—to offer temporary maintenance grants and other aids to re establishment The spread of racial doctrine to Italy the consequences in Austria and Czechoslovakia of the political events of 1938 and their reactions in neighbouring countries the continuation of civil war in Spain the extreme xenophobia of the U S S R and recent events in Germany all these have added to the need for information and advice on one hand for direct assistance on the other When a ship is in distress no sailor and few landsmen will not want to go to its help

The Society has just issued its annual report from which it appears that a widespread appeal is shortly to be issued for funds on one hand for interest and sympathy through membership on the other The problem has been complicated and enlarged by the events of 1938 but the Society has not turned aside from its original purpose and principles It exists not to advertise a particular point of view but to do an honest job of work in seeing that ability and experience in science and scholarship are not wasted It does not it cannot disregard human values but its charity is devoted to those who can contribute to the common stock of learning It stands for the brotherhood of scientific endeavour regardless of race and creed and politics and it stands for it not by passing pious resolutions or by putting out disguised political propaganda but by trying to help colleagues in their need Foreign scientific workers are found work which restores their self respect and makes others realize their value in their common task so that not seldom they become self supporting From the start however the Society has done its best to avoid any unfair competition of exiled scientific workers and other scholars with those in the countries where they are seeking refuge and has realized and urged that in the long run such competition is as little in the interest of the exiles as in that of scientific workers as a whole

The Society must maintain its authority and integrity in the face of its increasing task In Germany alone fourteen hundred university teachers and research workers have been displaced many of them among the most distinguished in the world not merely debarred from teaching and research they are not allowed to make a living at all More than four hundred Austrian men of science and other students have been displaced and of these only about a hundred have been able to leave the country The full effects of the racial policy in Italy and of the partition of Czechoslovakia have yet to be felt Spain from which scholars of both parties have been helped is still no place for tolerant sensitive academic people and the U S S R has disappointed our hopes by turning out those who originally found work and refuge there

Caution in the circumstances must often seem intolerable to humane men but the Society's stringent caution in accepting responsibility bears fruit Work has been found permanently for about 550 scholars in thirty eight different countries from Australia to Venezuela for about 330 temporarily in twenty five countries Turkey which is building a new civilization has welcomed numbers of the displaced university men

In November 1937 the Society called an informal conference at Oxford of representatives of European universities and the ideal of an international exchange for information and employment came nearer to realization The Society's register of exiled scholars is now unique authoritative and international Any academic or research institution can have the benefit of its records of those exceptional abilities exceptionally trained lost to their own countries but not if the Society can prevent it to the service of knowledge anywhere else in the world

Funds and interest are however an imperative need first for the work of administration information and advice secondly for direct help in human emergency It is to be hoped that the wider educated public particularly in the English speaking countries will respond generously to the appeal for support which the Society is making and come to the help of science and learning in distress

Serialism and Immortality

The New Immortality
By J W Dunne Pp 157 (London Faber and Faber Ltd, 1938) 3*s* 6*d* net

THIS little book is intended to supply the general reader with a more or less popular account of the theories about time and the self which Mr Dunne has developed in considerable detail in his previous works An Experiment with Time and The Serial Universe Mr Dunne thinks that these theories are entailed by certain quite general facts about time and change on one hand and about self consciousness on the other The former reduce to the linguistic fact that we talk of future events as becoming real or 'coming into existence of past events as having ceased to be real or having passed out of existence, and so on The latter reduce to the linguistic fact that each of us uses expressions like my self and your self which seem to imply in the case of each of us the existence of an owned self and an owning self and an I which knows them both and sees that the one owns the other

Mr Dunne assimilates this latter distinction with another about which he makes much ado This is the distinction between a recording instrument for example a magnetometer a body which influences it in virtue of one of its properties for example a magnet and the reading which the instrument records when thus influenced Mr Dunne thinks that we are liable to confuse the reading of the instrument with the agent which causes the instrument to record this reading and that many important consequences follow on which the distinction throws a flood of light I find it hard to believe that anyone except an extremely eminent mathematical physicist engaged in writing extremely bad philosophy ever would make such a gross mistake

Taking these linguistic expressions literally and seriously Mr Dunne quite correctly infers that he is committed to an endless series of times and an endless series of observers He also infers that each term in the series of times reduces all the previous terms to additional dimensions of *space* Time would be the last term of a series which from the nature of the case would have no last term This appears to me to be a plain *reductio ad absurdum* of Mr Dunne s theory He disguises it from himself by talking airily about the observer at infinity and by palpably false analogies with infinite series which have upper limits

Mr Dunne thinks that his theory is supported by certain empirical facts about dreams He also claims to show that the characteristic features of the special theory of relativity and the quantum theory are necessary consequences of his serial theory I have never been able to follow this deduction even in the full exposition of it in The Serial Universe , one part of it appears to depend on a juggle with the square root of minus one based on a misapplication of Argand s diagram I should think that the condensed form of it in the present work would be completely unintelligible to all readers

The main object of this book is to expound and illustrate a theory of immortality which is closely bound up with the serial theory of time and the self The first order observer collapses with the death of the body but the higher order observers are unaffected Although they can get no more sensory experiences they retain and can rearrange in any order they like those sensory experiences which were obtained before death by use of the first order observer Mr Dunne explains and illustrates this theory very well by analogies with music and with typewriting Even if Mr Dunne s general theory were intelligible and true he produces no cogent positive reason for holding that the higher order observers would survive the death of the body He is content to argue by what seem to me to be quite unconvincing analogies that the burden of proof lies on anyone who doubts this However this may be if the theory is self contradictory as I believe it can lend no support to any conclusion C D BROAD

Birds of Britain

The Handbook of British Birds

By H F Witherby (Editor) Rev F C R Jourdain Norman F Ticehurst and Bernard W Tucker Vol 2 (Warblers to Owls) Pp xiii + 352 + 30 plates (London H F and G Witherby 1938) 21s net

THERE are to be five volumes of the Handbook of British Birds and the second volume which has just been published deals with the warblers the thrush family wheatears whinchats and redstarts nightingale and robin hedge sparrow and wren the water ousel the swallow and the swift family the nightjar and the kingfisher the woodpeckers and the wryneck The cuckoo and its strange habits are described and there is a series of photographs of a young cuckoo in the act of throwing an egg out of the nest The latter part of this volume is given up to the owls –the snowy and the short eared owls the little owl and others

It is stated that the reception of the first volume has been most gratifying and the second volume is fully up to its high standard The illustrations are clear, and the coloured plates especially helpful A series of valuable diagrammatic maps are incorporated in the text H F Witherby has compiled three of these maps The first shows the breeding distribution in the British Isles of the reed warbler the second shows the nesting distribution of the greater spotted woodpecker and the third the breeding distribution of the little owl in Britain It is by the way of interest to know that a full inquiry has proved that this alien owl introduced in Britain during the nineteenth century is not so destructive as is generally supposed but Mr R M Lockley has shown that they work great havoc among storm petrels when they take up their quarters on islands where the petrels are nesting

Other maps in the book show the breeding distribution of the nightingale (N F Ticehurst) and the recovery in Africa of swallows ringed in Europe (L Schuz)

In an interesting map compiled by H N Southern is shown the northward migration of the swallow through Europe during spring and early summer Mr Southern has found that swallows make the northward flight from Spain to the north of Norway a distance of more than two thousand miles in about seventy seven days at a fairly steady rate The average date of the arrival of the swallow in Spain and Italy is March 15 and in the north of Scandinavia June 1 It is to be hoped that Mr Southern may later compile a similar map showing the northward migration of the swift and that he may be able to explain the late northward movement of these birds which the reviewer has seen flying northward at a great height over the Cairngorms in mid June and again passing north east over the Isle of Skye (where the swift does not nest) at the same time of year

Presumably these swifts are travelling to the most northerly limit of their breeding range

There is also in this volume a helpful chart of the song periods of British birds compiled by H G Alexander

Not the least admirable feature of these Handbooks of British Birds is their accuracy a standard difficult to attain to as new species and subspecies of birds are yearly being discovered It is a number of years since the Hebridean thrush was separated as a distinct species from the British song thrush In the Isle of Skye in the reviewer s experience the range of the Hebridean thrush is interesting In the treeless district of the north west of Skye which is only sixteen miles from the nearest of the Outer Hebrides the resident thrush appears to be the Hebridean thrush These birds are very tame and can be watched closely But in the east and south of Skye in the woods and gardens of Portree Broadford and Sleat the song thrushes appear to be an intermediate form between the British song thrush and the Hebridean song thrush

In the volume under review the song period of the Hebridean song thrush is stated to be from February until the end of June This rather under estimates the duration of song as the bird is habitually in full song during the first three weeks of July and sometimes when it nests late is heard in full song until mid August singing as is its custom from a house top or from a wall or from a patch of whins The song of the Hebridean thrush is softer and less assertive than the song of the British song thrush and the reviewer has noticed that particular phrases are less often repeated

A large immigration of thrushes not of the Hebridean form takes place each October to the north west of Skye and the birds appear to remain along with immigrant blackbirds throughout the winter

In reading the records in this book one is struck by the number of rare birds recorded from Fair Isle that small and lonely island lying in the Atlantic midway between Orkney and Shetland Here such rare British visitors as the rock thrush Eversmann s warbler red rumped swallow needled tailed swift red spotted bluethroat and white spotted bluethroat—to name only a very few—have been recorded It is seldom that an island on the track of migrating birds has an accurate observer residing on it but Mr Stout the postmaster of Fair Isle is an enthusiastic and competent ornithologist

It is necessary to say in recommending this latest volume in this practical Handbook series that it is a book which the amateur bird enthusiast as well as the expert cannot well be without if she or he is to remain up to date in bird watching and in bird lore S (

Theoretical and Practical Organic Chemistry

(1) Organic Chemistry
By Prof Frank C Whitmore Pp x + 1080 (London Chapman and Hall Ltd 1937) 40*s* net

(2) Systematic Organic Chemistry
Modern Methods of Preparation and Estimation By Prof William M Cumming Dr I Vance Hopper and Prof T Sherlock Wheeler Third edition revised by William M Cumming and I Vance Hopper Pp xxvi + 548 (London Constable and Co Ltd 1937) 25*s* net

(3) Laboratory Practice of Organic Chemistry
By Prof G Ross Robertson Pp xi + 326 (New York The Macmillan Co 1937) 10*s* net

(1) PROF WHITMORE has written a one volume reference text designed for those already possessing reasonable knowledge and experience in organic chemistry It is certainly a long time since an author has claimed to treat the whole of organic chemistry in a single volume of rather more than 1 000 pages Of the book 0 57 is given to the description of the aliphatic compounds 0 07 to the alicyclic compounds 0 17 to the aromatic compounds 0 08 to the heterocyclic compounds and 0 11 to the index which comprises no less than 122 pages This index has a character of its own under linkage for example references to twenty three different types are given It is not only an index but also a special type of dictionary of organic chemistry No organic chemist will be surprised that Prof Whitmore has been occupied during eight years in making this most readable and so far as a reviewer can test it accurate and up to date compilation

Whether the book will satisfy the majority of organic chemists would appear to be doubtful In certain directions the subject matter is adequate in others it is otherwise Only one synthesis of indigo is referred to in outline in two and a half lines alizarin and camphor are likewise summarily dealt with These are examples of isolated and fundamentally important compounds with which the author may expect his readers to be already acquainted Taking a group of compounds if the carbohydrates and glycosides can be successfully discussed in forty one pages Prof Whitmore s treatment is a model of compression

The successful learning of organic chemistry largely depends on the manner of use of original literature by the student In many cases Prof Whitmore gives references only to the name or names usually not more than two of the worker or workers whom he judges to be outstanding This is not wholly satisfactory and many will disagree with the author s opinion Probably to save space references to original literature are not given and it is interesting to know that an American author considers The Annual Reports of the Progress of Chemistry published by the Chemical Society in London worthy of repeated reference because they offer excellent summaries

Prof Whitmore s Organic Chemistry may be styled an excellent summary If this modern text book be compared with the much older and almost classical Lehrbuch der Organischen Chemie of which Victor Meyer and Paul Jacobson were the original authors many deficiencies appear and one may regret that no one seems inclined nowadays to emulate the work of these two famous chemists and those who have attempted to bring their work up to date

(2) The second volume under notice is a practical book deserving of high commendation It has a reputation of fifteen years and this is the third edition In plan and contents it is in the front rank of text books for the successful training of the students in the practical side of organic chemistry

After two chapters dealing adequately with the most general types of reactions in organic chemistry apparatus and methods including details regarding the determination of constants of pure materials and modern methods for the separation of mixtures the preparation and reactions of classified organic compounds are fully illustrated Then follows a section dealing with the electrolytic preparation of typical compounds the preparation of pure compounds from naturally occurring materials and of stereoisomeric compounds which indicates something of the comprehensive character of the practical training outlined by the authors

It would be difficult to improve on the section dealing with quantitative methods The authors fully justify the inclusion of macro micro and hemi micro methods of analysis of organic compounds and it is clear they deprecate the tendency in certain schools to omit exercises in ultimate analysis since micro methods have come into common use and are now to a great extent carried out by professional analysts It might add to the value of this section if other alternative methods of determining say bromine and chlorine were introduced in later editions

A useful list of reactions of certain important types of organic compounds and a comprehensive index complete this book which brings successfully the work of the lecture room into the laboratory It would appear that the only drawback is the omission of the year of the volume from references to original literature and specialized text books Particularly for students the year is more important than the actual volume number the use of which has now been abandoned by the Chemical Society

(3) Prof Ross Robertson s guide to practical organic chemistry is much smaller than that by Prof Cumming and his colleagues and both books are departures from the older books on the subject which are largely detailed working recipes

One third of the present volume is taken up by a critical discussion of the principles of manipulation and the elementary physical chemistry on which depends the separation of solid and liquid organic compounds from mixtures The remaining two thirds of the book is devoted to laboratory experiments on the preparation and properties of organic compounds These are not intended to be comprehensive and have been discriminately selected with the view of carrying out a limited number of typical reactions rather than a large number of those having little relationship to each other Other more comprehensive books are referred to including that by Prof Cumming and his colleagues and this portion of the book is particularly well written Each typical exercise is preceded by a theoretical statement briefly summarizing important details concerning the physical and chemical properties of the particular substance and the best conditions for realizing the reaction or reactions concerned Then follow the details of the actual preparation and the isolation of the product a list of other analogous preparations with references and finally a number of questions arising out of the methods of procedure which have been adopted in this and analogous cases

There is a brief account of the qualitative analysis and identification of certain types of organic compounds but the author has omitted any reference to their ultimate quantitative analysis This could easily be included in a subsequent edition if the author wishes to make the course he outlines even more useful than it is already for training for original investigation

The book is well printed with clear diagrams Altogether it can be recommended as a useful critical treatment of the principles of practical organic chemistry CHARLES S GIBSON

Plant Ecology

Plant Ecology
By Prof John F Weaver and Frederic E Clements Second edition (McGraw Hill Publications in the Botanical Sciences) Pp xxii+601 (London and New York McGraw Hill Book Co Inc 1938) 30*s*

THE first edition of this text book was published in 1929 with 520 pages The short preface to the new edition dated January 1938 points out in concise phrases some of the more important advances in plant ecology made in less than a decade The wide acceptance of succession is a basic principle in the study of vegetation has led to a better understanding of invasion ecesis and the stabilization of climax vegetation The use of plant species and plant communities as indicators the changed concept of xerophytism and improved methods of studying the environmental factors are among the advances which are enabling the ecologist to grasp the complex interactions of plant life Particularly important to the plant ecologist are the new conceptions of the vast importance of climate and vegetation in soil development On the applied side too plant ecological studies are making great advances Erosion largely due to man s misuse of the natural plant cover has been realized as a problem of national and international importance

Ecology suffers in its presentation from an inherent drawback which is not so evident in some other biological subjects It depends very much upon taxonomy and floras differ greatly in different parts of the world The synecologist has to name and ecologically to describe and classify the species components of the vegetation with which he is concerned It follows that much of his description can only be followed or at least fully appreciated by biologists familiar with the local flora

In text books the general principles have to be exemplified by reference to plants the very names of which may be new to foreign readers many of whom will certainly have no personal acquaintance with the plants themselves An ecological text book has therefore its greatest value in one country that from which the author takes his examples The authors of the work here reviewed take the vast majority of their examples from North American vegetation While it is true that they have not overburdened their text with plant names and illustrate the book freely with photographs and other reproductions most of the species mentioned and a fair proportion of the genera will be unknown to most British readers Differences of size climate physiography and economic history between the United States and the British Isles also hinder this book from being an ideal text book for use in the latter On the other hand the enthusiasm of the authors for their subject the very full statement of general principles and the comprehensive bibliography (of 1035 references) must make the work extremely valuable for reference It is so far as Great Britain is concerned a book for the teacher rather than for the school or college student and as such it can be heartily recommended W B TURRILL

Iris Patterns and their Inheritance

Structural Variations of the Human Iris and their Heredity
with Special Reference to the Frontal Boundary Layer By Dr Viggo Eskelund Pp 243 (Copenhagen Nyt Nordisk Forlag Arnold Busch London H K Lewis and Co Ltd 1938) 21*s* net

THE laws of inheritance of blood groups and types are now so well established that in certain cases paternity can be definitely excluded Dr Eskelund believes that the various patterns of iris found in man could also be classified on an hereditary basis and eventually perhaps provide equally good or even better evidence of paternity

In a laborious study of photographs of the living iris in 154 subjects conducted under the auspices of the P Carl Petersen Foundation at the University of Copenhagen he has arrived at certain preliminary conclusions which will interest without convincing most of his readers He holds that iris pattern can be definitely classified into types To achieve this one must take the anatomical conditions of the various regions (for example anterior and posterior layers of the stroma uveal border presence or absence of crypts depth of colour and distribution of chromatophores etc) and arrange them under headings of combinations of variables

The author s description of the various types is rendered slightly difficult for English readers by the use of an unusual terminology For example his frontal boundary layer is what we are accustomed to call the anterior layer and his scratches are small crypts The photographs are beautifully reproduced but it would be easier to follow the suggested classification if Dr Eskelund had used a higher magnification in examining the eye before photographing it It also seems doubtful whether he has described anything like the possible number of types There seems for example to be little or no reference to racial differences which are often great or to the effects of racial interbreeding

It will certainly be generally admitted that there is some hereditary factor influencing iris pattern Indeed this has been shown already by the work at the Galton Laboratory on both normal and pathological irides in man and animals To what extent however reliance can be placed on a classification necessarily rough to subserve any medico legal purpose is uncertain It is probable that iris pattern is as individualistic as finger print pattern and it might prove to have an even greater identification value since it cannot be obliterated Its value in proving heredity must however remain doubtful until many more pedigrees of several generations have been examined in different races

Fossil Gastropods

Handbuch der Palaozoologie
Herausgegeben von O H Schindewolf Band 6
Gastropoda Lieferung 1 Teil 1 Allgemeiner Teil und Prosobranchia Pp viii + 240 (Berlin Gebruder Borntraeger 1938) 45 gold marks

ALTHOUGH students of most nationalities are now well provided with text books of palæontology no comprehensive work of reference giving a complete survey of existing knowledge of the subject has appeared since the publication of Zittel s famous Handbuch der Palæontologie (1876 1893) To remedy this deficiency a new Handbuch (a term the connotation of which appears to have undergone a process of evolution) is now in course of preparation under the general editorship of Prof O H Schindewolf The collaboration of nearly fifty specialists belonging to several nationalities has been secured for this work which it is proposed to publish in twenty volumes the majority of which will consist of several *Lieferungen* The appearance of the first part of this huge undertaking is thus an event of some importance to palæontologists

The author Dr W Wenz is well known as an authority on the Cainozoic non marine Gastropoda and the compiler of the very substantial section of the Fossilium Catalogus which deals with this group Even for such an indefatigable worker the preparation within a few years of a treatise defining and classifying every recognized genus and subgenus of the Gastropoda from the Cambrian faunas to those of the present day must have been no mean task It is true that M Cossmann s Essais de Paléoconchologie Comparée (1895–1925) not quite completed owing to its author s premature death has to some extent paved the way for this work by assembling an enormous quantity of data concerning the range and distribution of the various groups and by giving good descriptions and figures of genotypes So far as the Palæozoic genera (with which the present part mainly deals) are concerned however Dr Wenz does not appear to have been much influenced by the ideas on classification advanced by his predecessor

The general scheme of classification adopted is that given in J Thiele s Handbuch der systematischen Weichtierkunde (1929 1935) which is likely to remain the standard work of reference on the Recent Mollusca for some time to come Except for a series of introductory chapters which include a useful review of modern ideas on gastropod phylogeny the present part deals entirely with the Archæogastropoda the first of the three orders into which the subclass Prosobranchia is divided Much of the detailed classification proposed is certainly new a great part no doubt is merely tentative in view of the dissimilarity of many of the groups dealt with to Recent forms of known anatomical characters It would have been preferable if the author had indicated which families are erected for the first time

In matters of nomenclature this work appears to conform strictly with the International Rules and no attempt has been made to perpetuate obsolete names by the arbitrary selection of *nomina conservanda* The wise decision has been made to dispense with the section as a taxonomic group subsidiary to the subgenus Well printed text illustrations almost entirely copied from pre existing works illustrate the most important genera

The Genus Youngia

By Ernest B. Babcock and G. Ledyard Stebbins, Jr. (Publication 484.) Pp. iii+106+5 plates. (Washington, D.C.: Carnegie Institution of Washington, 1937.) n.p.

THE genus *Youngia* was described more than a century ago by Cassini, but the characters on which the genus was based did not preclude the inclusion within it of species of several allied genera of the *Cichorieæ*, and Cassini's species have long been merged in the genus *Crepis*. During his long study of the taxonomy and genetics of the latter genus Prof. Babcock has repeatedly come in contact with certain Asiatic species invariably included in the genus *Crepis* which appeared generically distinct. For the reception of these species the genus *Youngia* has been re-established and redefined.

Twenty-seven species, six of which are newly described, are included in the re-established genus which is divided into six sections. The species mainly inhabit China with extensions westwards to Ceylon, Kashmir and the Pamir-Altai cordillera and eastwards to Formosa and Japan. The monographic treatment includes discussions of the interrelationships of the sections and of the species within the sections, whilst admirably clear illustrations are given of all the species and subspecies. Two of the more widely distributed and polymorphic species which have been studied genetically show that variability is associated with polyploidy and parthenogenesis probably resulting from hybridization. This has led the authors to refrain from naming lesser variant forms which are merely listed by number after the appropriate species. The major subspecific entities receive names but their citation as trinomials is to be regretted. The comparative scarcity of herbarium material consequent upon the remoteness of the localities at which many species occur will certainly lead to future additions to, and perhaps modifications of, the authors' arrangement; yet the work will remain of lasting value in having for the first time brought together and clarified the relationships of a group of species the previous systematic treatment of which has been unsatisfactory. W. A. S.

Modern Methods of Refining Lubricating Oils

By Vladimir A. Kalichevsky. (American Chemical Society Monograph Series.) Pp. 235. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1938.) 30s. net.

IN the United States, the older cruder methods of refining are fast becoming obsolete and are being everywhere replaced by solvent processes, which have the great merit of removing the unsatisfactory asphaltic constituents generally termed naphthenics. In addition, the systematic use of additives for improving certain particular characteristics is beginning to become of commercial importance. The time is ripe for the description and discussion of these new methods of refining and the general principles which underlie them: it is now provided in handy book form by Mr. V. A. Kalichevsky, as one of the well-known American Chemical Society series of monographs.

The solvent refining processes represent a great advance in chemical engineering and are characterized indeed by considerable daring as, for example, in the use of liquid propane as a solvent. They are continuous and even involve the use of two solvents which carry the separated constituents of the crude oil in opposite directions.

Besides removing the asphaltic constituents, a second separate solvent treatment is used to remove the high melting waxes so that the final products are straw coloured fluid oils which do not thicken even at the low temperatures experienced in high flying.

The book tells the full story in a practical manner and should be welcomed by a large number of those engaged in the lubricating industry. E. F. A.

The Children's Play Centre

its Psychological Value and its Place in the Training of Teachers. By D. E. M. Gardner. (Contributions to Modern Education.) Pp. xv+143. (London: Methuen and Co., Ltd., 1937.) 3s. 6d. net.

WE refer to this book not so much because of its detailed account of the working of a play centre, a subject which is somewhat outside our province, as because we think it exemplifies a really scientific approach to the problems of child study. As Dr. Susan Isaacs points out in her foreword, young teachers find it difficult to connect the generalizations of their text-books of psychology with their own experience, or with the actual children they have to face in the schools. In fact, they begin at the wrong end. They are led to disobey the accepted rules of pedagogic and of scientific method. From this mistake the play centre, where children can be observed under the most natural conditions, provides a way of escape. Let the young teacher begin there and the text-books will convey far more meaning than they usually do at present.

The Observer's Book of British Wild Animals

Compiled by W. J. Stokoe. Pp. 224. (London: Frederick Warne and Co., Ltd., 1938.) 2s. 6d. net.

THIS is the fifth of a series of handy pocket books (see also NATURE, 141, 351, 1938), one of their merits being that they actually are pocket books, 5½ in. by 3½ in., and therefore convenient to carry on nature rambles. In this volume, sixty-nine species of British animals are described, and the text is illustrated by seventy-two illustrations, forty-six of which are in colour. Naturally, most of the book is devoted to mammals, but the few British reptiles and amphibians are also described. The term 'animals' in the title is used in the common, but erroneous, sense. However, so far, birds and butterflies have been dealt with in previous volumes. Thus, the present volume concludes in this series consideration of all terrestrial vertebrates. To those interested in the natural history of the countryside, this "Observer's Pocket Series" can be strongly recommended.

Cultural Contacts of Science*

By Sir Richard Gregory, Bart., F.R S.

IN the study of man and his activities three types of cultural development may be recognized and they are all measured by different standards In the Fine Arts the imaginative qualities of the mind appeal primarily to the emotions through stimulation of the æsthetic judgment material culture is the province of mechanical arts and science—the domain of reason—is systematic and formulated knowledge in all fields of human understanding—natural moral social and political Natural science or natural philosophy is only one division of science as thus defined The history of civilization is a history of intellectual development in which science has been the chief factor in changing habits of thought from superficial observation and speculative and anthropomorphic theories of causation to clear concepts rational conclusions and progressive principles in the advancement of man and society

In the most primitive times man had to acquire knowledge of the world of Nature around him in order to survive The effort to secure the food and shelter necessary for his existence demanded a never ceasing exploitation of the resources of his environment for the progressive improvement of his material equipment—an equipment which he learned to turn against his fellow man no less than against the animal world upon which he preyed for food and clothing or against which he must defend himself But in this struggle even more than on his personal prowess his skill and his knowledge of the habits of food plant and animal man relied upon his imagined understanding of and his supposed power to control the hidden causes of the nature and behaviour of the beings and objects of his world—in other words his will to survive was rooted in magic Though the magical beliefs of primitive man may seem to us vain and crude let us not despise them for in these blind gropings to probe causation in Nature we may see the remote and humble beginnings of the urge to the understanding of the universe which is science

It is not, however with man s progress in relation to material development with which we are now concerned but with the contacts of science with what is known as polite' learning—literature religion, and other expressions of the human spirit The noblest aims of man are not represented by great industrial advances but by the search for the truths upon which they are based and by the influence of this effort upon personal and social ethics These intellectual or spiritual associations of science were more common in former times than now when we are passing through or perhaps as it may be just emerging from a materialistic age in which they tend generally to be neglected

The Fine Arts and literature are usually confined to the expression of what are understood to be the eternal verities of life and so long as this is so though their form of expression may change a supreme standard of excellence may be reached in any epoch In the fourth and fifth centuries before the Christian era the works produced by the artistic and literary genius of the Greeks are masterpieces which will command admiration for all time and ancient Rome India and China have each had a golden age of artistic and literary achievement Similarly in western Europe architecture painting and poetry have reached the highest level of excellence at various epochs and then suffered a decline Apart from the development of technical excellence progress in any of these arts of expression can only be in the elaboration and enrichment of creative ideas but the store of these is not thereby increased and each age—each type of civilization—must work out its own ideals Artists may aspire to emulate the paintings of Raphael or Leonardo da Vinci but they cannot use the works themselves as a background upon which to add their own conceptions

Science however differs from the Fine Arts in the fact that every discovery extends the boundaries of knowledge and may be the starting point of further progress It was upon the foundations laid by Kepler and Galileo that Newton was able to construct the universal law of gravitation and it is by the succession of such discoveries that science advances while the picture it presents is continually being enlarged and having new details added to it The time may come when art and literature will be moved by such achievements of the human mind to make manifest their real meaning and the imagination will be so quickened by the spirit of man reaching out to the stars that artistic and literary response to the beauty and mystery of Nature will be deeper than ever before

Associations of science with literature in former times are chiefly connected with astronomy—the oldest of the sciences and the one most closely united with spiritual feeling. At the beginning of the history of civilization, the sun and moon were given divine attributes as well as used to mark the times of operations of life in days, months and years. Five thousand years ago, the Babylonians and Egyptians possessed a considerable store of knowledge of the skies. The constructions of the great temples and pyramids of Egypt, as described in preserved records, and shown in existing remains, are of particular astronomical interest as well as for the study of mythology and religious belief. One of the most impressive structures of this kind, the remains of which still exist, is the great temple of Amon Ra at Karnak, near Luxor, the length of which is about five hundred yards with the open end pointing in the direction of the setting sun at the summer solstice. The rising of the star Sirius—the brightest in the heavens—just before the sun in July of each year heralds the annual inundation of the Nile and was used by early Egyptians to mark the beginning of a new year.

---

* Outline of the Elihu Root Lecture delivered at the Carnegie Institution of Washington on December 8 and to be published by the Institution in book form

Observations of groups of stars seen just above the sun at dawn or at twilight were associated with seasons and other events on the earth in very early times. The groups were figures on a celestial dial, and the sun took a year to pass round the complete circle of the heavens upon which they were fixed. The division of the circuit into twelve parts or signs made up the Zodiac as recognized and used for religious and seasonal observances by the Chaldeans, the Chinese, the Egyptians, Hindus, Persians, Greeks, Romans, and other peoples. The twelve signs or constellations of the Zodiac seem to be referred to in Joseph's second dream and in Jacob's blessings of his children.

The sun as the source of all heat, light and life on the earth was the central object of religious belief of most early peoples. Whether it was worshipped as the god itself or as his symbol even by the priests, is doubtful; but for a short period in the history of Egypt about thirteen hundred years before the Christian era, King Akhnaton, or Akh-en-Aten—signifying "The Blessed of the Disk"—the Sun god was certainly worshipped as the one and only god, and the belief was, therefore, monotheistic. The finest expression in Egyptian literature is found in Akhnaton's "Hymn to the Sun Disk". Similar hymns are found in the "Rig-veda", one of the four sacred books of the Hindu scriptures, where light is associated with moral and intellectual values, as well as with physical properties.

Astronomy was thus studied by early peoples not only for practical purposes but also for religious observances. The gods or natural forces which determined the movements of celestial bodies were regarded as also ruling human nature. Astronomy and astrology were then combined in a single study. In the sixth century before the Christian era, Greek philosophers separated the conceptions of the influence of gods from the study of impersonal Nature, the laws of which were discoverable by the proper and methodical application of the human intellect. They first introduced the word φυσις, denoting *Nature*, to signify natural philosophy as apart from theology and mythology. The Hebrews also made a distinction between the worship of God and His works; but they saw all things as testimonies to the wisdom and power of the Almighty—as subjects of wonder and spiritual exaltation rather than as matters of intellectual inquiry.

There are many references to astronomical objects and phenomena in classical Greek literature from the sixth century B.C. onwards. The earliest Greek work on astronomy is that of Eudoxus transmitted in verse by Aratus—third century B.C.—who mentions forty-four constellations. A commentary upon their works was written by Hipparchus, who was as great an astronomer as Aratus was a poet. Ptolemy (A.D. 100–178), who was the definitive authority on astronomy of the ancient world, enumerates forty-eight constellations; and these with few changes, are still used by astronomers to mark the grouping of stars in the sky.

Aratus's astronomical poem was esteemed by both Christian and pagan philosophers. When the Apostle Paul spoke to men of Athens on Mars' Hill he referred to Aratus when he remarked "as certain also of your poets have said: For we are also his offspring". The words used by St. Paul follow very closely passages in the text of the poem of Aratus. Cicero and other writers translated Aratus's poem into Latin; and several Roman poets, including Virgil, quoted largely from it. In his great didactic poem, the "Georgics", Virgil brings man into intimate contact with Nature by describing the relationship between agricultural operations and the constellations visible at different seasons. In the same period, Lucretius produced his great work "On the Nature of Things", which is more remarkable for its anticipation of modern views as to atoms and their relationship to space than for its description of scenes or actions in the celestial drama as viewed from the earth. His purpose was to present a theory or theories which would explain natural things and laws without assuming the existence of deities as legislators.

During the period from the ninth to the fourteenth century, when the study of natural knowledge was cultivated by the Arabs with conspicuous success astronomy was given particular attention and Arabic works upon it translated into Latin were afterwards widely read Omar Khayyam who lived in the latter half of the eleventh century was an astronomer as well as a poet though there are few astronomical references in his Rubaiyat He lived in the golden age of Arabic science and the next great poetic genius was Dante who made detailed and accurate use of the scientific knowledge of the times Dante derived his knowledge of celestial objects and movements from a celebrated Arabic astronomer Alfraganus who flourished at the beginning of the ninth century and wrote a number of works on the sundial the astrolabe and other astronomical subjects Chaucer was another astronomer poet who was indebted to Arabian science for much of the astronomical knowledge revealed in his works He was the first great master of English verse and his poems contain many references to celestial subjects chiefly from the point of view of their relationships to human life and events

Three centuries after Dante Milton in Paradise Lost described many astronomical objects and phenomena Milton met Galileo and in well known lines refers to the astronomer s observations of the moon and the Milky Way He knew the Copernican system of the universe which was established by Galileo s observations and described the differences between it and the Ptolemaic system which was then generally accepted but he left the question unanswered as to which system should be accepted as true Even Francis Bacon persistently rejected the Copernican theory though there were eminent men astronomers and others anterior to or contemporary with him who adopted and taught it The theory had been before the world for nearly eighty years before Bacon s Novum Organum was published and he gave great attention to the methods by which astronomy ought to be studied yet he refused to accept the theory and constructed an elaborate celestial system of his own Even after the discovery of the satellites of Jupiter by Galileo in 1609 seventeen years before his death Bacon opposed the Copernican view that the earth moved in an annual orbit around the sun It is unfortunate that a philosopher with such a wide range of knowledge whose object was to show others how science could be advanced did not appreciate the simplicity of the Copernican theory as an explanation of celestial movements In this respect however his attitude was that of many of his contemporaries including those not influenced by theological prejudices as well as Catholics and Protestants.

The adoption of the Copernican theory meant that the foundations of belief in the earth and man as centres of the universe were destroyed Later when Newton had shown that the law of gravitation was sufficient to account not only for the movements of the planets but also for the paths of comets it was no longer reasonable to believe that these were sent as signs or warnings to the human race The intellectual expansion thus brought about together with the sense of justice which resulted from the existence and permanence of law in Nature profoundly influenced human thought and resulted in social changes which had the greatest civilizing effects

A similar revolutionary adjustment of thought had to be faced when three centuries after Copernicus man was placed in a new relationship to the rest of living creatures and shown to have a sub human ancestry The principle of evolution gives new hope to life and the promise of a golden age in the future instead of the past if man follows his highest ideals for as T H Huxley pointed out evolution embodies the idea of progressive social and ethical standards as well as development of physical structure Any nation or people which separates itself from the rest of the world in the name of race or religion and cultivates ideals of conquest by force in order to assert its claims is reverting to the law of the jungle and retarding the higher evolution of mankind

The view that the sole function of science is the discovery and study of natural facts and principles without regard to the social implications of the knowledge gained can no longer be maintained It is being widely recognized that science cannot be divorced from ethics or rightly absolve itself from the human responsibilities in the application of its discoveries to destructive purposes in war or economic disturbances in times of peace Men of science can no longer stand aside from the social and political questions involved in the structure which has been built up from the materials provided by them and which their discoveries may be used to destroy It is their duty to assist in the establishment of a rational harmonious social order out of the welter of human conflict into which the world has been thrown through the prostitution of the rich gifts with which they have endowed the human race Science has made the world one through the facilities of transport and communication now available and it recognizes no political or racial boundaries in the fields of knowledge By the wise use of this knowledge the earth could indeed become a celestial dwelling place instead of a world of dust and ashes which prevailing conditions seem to be making its destiny

The Electron Microscope

By Prof L. C Martin, Imperial College, London

INTRODUCTORY

IT has been known for many years that cathode rays can be deflected by electric and magnetic fields but in 1926 Busch showed that axially symmetrical fields would have the power of focusing such rays much as light is focused by a lens

Any axially symmetrical lens system will produce a fairly sharp optical image of objects near the axis provided that the aperture is so far reduced that only rays travelling very close to the axis are allowed to pass through the system and provided moreover that strictly monochromatic light is employed This reduction of the aperture is essential in general to avoid the spherical aberration of the rays which make larger angles with the axis and the consequent deterioration of the definition of the image but on the other hand the finite wave length of light causes a spreading of each image point such that the spread is inversely proportional to the aperture of the lens system This tendency makes it impossible to retain very sharp images with optical lenses of smaller and smaller angular aperture and highly complicated lens systems have to be used to allow of the attainment of large apertures without concurrent spherical aberration Thus in the relatively simple case of the ultra violet microscope objective (numerical aperture 1 2) five or six specially shaped lenses mounted with the greatest care have to be used but the resolving limit cannot be brought much below about 0 15 μ without great difficulty In other words the closest approach of two object points compatible with the separation of their images is about one seven thousandth part of a millimetre

POSSIBILITIES OF THE ELECTRON MICROSCOPE

Until the origin of the electron microscope it did not seem possible that this limit would ever be lowered very considerably but once the possibility of forming images with electrons was realized it became apparent that further progress was possible The experiments of Prof G P Thomson and others had shown that the wave lengths of the waves associated with medium velocity electrons are only about a hundred thousandth part of the wave length of ultra violet light, and therefore the relative aperture of an electron optical system could be lowered drastically in order to avoid spherical aberration without incurring any considerable spreading of the elementary image points Such lenses have now been made which work at numerical apertures of much less than 0 1 but the residual spreading of the image is almost entirely due to other causes that is to chromatic aberration (due to the presence of electrons with differing velocities) to spherical aberration and to faulty centration together with the characteristic aberrations of extra axial image points The best of such images appear to have resolving limits of approximately 0 01 μ and will bear magnifications up to 20 000 or more without losing apparent sharpness

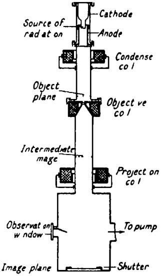

FIG 1

KNOLL AND RUSKA'S ELECTRON MICROSCOPE

The pioneer work in building such instruments was due to Knoll and Ruska working in Berlin (1932) They employed a cold cathode discharge tube as a source of electrons which were projected through a very small aperture along the axis of a highly evacuated tube (Fig 1) The electron beam passed in succession through ironclad coils representing the condenser the objective and the projection eyepiece of a microscope, and finally fell upon a fluorescent screen or photographic plate for the registration of the image The first pictures obtained were 'silhouette images of fibres perforated metal foils, and the like Then in Brussels

Marton made early experiments on the electron-photography of biological tissues impregnated with osmium, and of bacteria mounted on very thin films of nitro-cellulose In Great Britain an instrument was designed by the present writer and his colleagues in co-operation with Messrs Metropolitan-Vickers Electrical Co, Ltd, by whom it was made (Fig 2) It is intended to give special facilities in the microscopy of objects alternatively by light or the electron beam, and experiments with it have been in progress for the past two years The resolving limit attained is already better than that of the ultra-violet microscope, and Prof G P Thomson is directing a systematic investigation of various troubles preventing better definition Hot-cathode discharges are now being employed by the German workers

The results so far obtained on the Continent are wonderfully promising, although claims have been made in a few cases which do not appear to be justified by the photographs reproduced Exceptionally striking pictures of colloidal structures, for example, threads of nickel carbonyl, and particles of colloidal gold in a film of lithium borate, have been published by Beischer and Krause, after which the resolution of *Amphipleura pellucida* in dots seems a pedestrian performance In order to photograph bacteria, they are dried by a special process on an extremely thin film of collodion, and can be photographed without any other special treatment Photographs have been published (notably by von Borries, E Ruska, and H Ruska) showing various organisms such as *Micrococcus flavus* under extraordinarily high magnification, such as 16,000, one picture exhibits a fine structure, whatever its nature or origin, on the film around the dried bacteria, which could not possibly be observed in optical pictures (Fig 3)

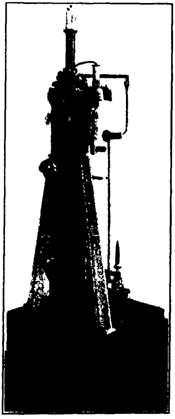

Fig 2

Electron microscope at the Imperial College, London

Fig 3

Micrococcus flavus, electron optical magnification, 16,000 Structures near the cocci do not occur in the supporting film, photographs of plain films show a completely clear ground Photograph by von Borries, E Ruska and H Ruska, reproduced by courtesy of Herr E Ruska, of Siemens und Halske A G

Delicate objects placed in an intense electron beam may of course suffer damage by heating and further by becoming so highly charged that electrostatic repulsive forces disintegrate the structure, it will therefore be understood that there is a great deal of special technique to be developed The necessity of mounting the objects in a high vacuum is naturally a severe complication

Thermionic Emission

The term 'electron microscope' has also been given to electron-optical systems designed to give images of surfaces which are self-emitters of electrons either by thermionic or by photo-electric action Thus, for example, suitably activated surfaces of iron and nickel vary greatly in emissivity according to their crystalline state, and the changes in structure with change of temperature can be followed in an interesting way by projecting the images of such surfaces with suitable magnetic or electrostatic lenses, although the magnifications employed are not usually greater than one hundred, and there is little question of high resolution The present article will not attempt to deal with these systems

PROBLEMS IN ELECTRON MICROSCOPY

Having briefly noticed the present state of progress in the subject it may be of interest to indicate some of the problems which have to be faced in any attempt at further progress

In an ordinary photomicrograph a picture' of an opaque object is formed by absorption of the light, but when the object is only distinguished by a variation of refractive index with respect to the surrounding medium, the contrast in the image is secured, in many cases, because some of the light from particular regions of the object is deflected outside the aperture of the objective and thus fails to reach the corresponding part of the image

In the case of the electron radiation passing through a thin layer of matter, a large proportion of the moving electrons may not pass sufficiently close to any of the electrons or nuclei in the atoms of the film to suffer perceptible changes in energy or direction, since, as we now understand, the particles conceived as forming an atom occupy effectively but a small part of its dimensions as usually estimated Other electrons may pass comparatively close to a relatively massive nucleus and swing around it in a hyperbolic orbit, suffering a comparatively large change of direction but, in comparatively many cases, inappreciable change of energy such collisions would be said to be of the 'elastic type

As has been shown by Bohr, however, the effect of the electrons present in the atom cannot be neglected , they are not to be regarded, in this connexion, as fixed, and thus can take up more or less kinetic energy from the particle in quantum units In some cases the moving electron interacts so violently that one or more electrons are completely removed from the atom , the loss of kinetic energy may then be comparatively great and accompanied by a large change in direction of the incident particle The collision is of the 'inelastic' type In some cases (fluorescence) the energy levels of the electrons of the material may be altered and light is emitted as they return to the normal configurations In very thin films of matter the electrons are not likely to encounter more than a single nucleus sufficiently closely for appreciable scattering, and the most probable angle of deflection is proportional to the square root of the thickness, but with increasing thickness or with the presence of heavier atoms at particular regions, the mean scattering angle may be increased, sometimes by successive encounters Some electrons may be completely trapped by the film and if it is a non conductor they remain as a charge on the surface

In preparing objects such as bacteria for the electron microscope, they are usually mounted on very thin films of nitro cellulose, and it is fortunate that the amount of scattering and spread of velocity caused by the film does not seem to be so great as to introduce serious trouble with spherical and 'chromatic' aberration Potentials of about 75 kv have usually been employed for this work If an object is mounted on a film, it will scatter the radiation to a greater extent than the film support, and, as widely scattered electrons will fail to enter the narrow aperture of the objective, the object will show up as a dark region in the image We have to remember, however, that the velocity spread caused by the mount may interfere to some degree with the definition, and the image will then differ to some degree from purely silhouette effects Thus the probability of detecting an object or separating the images of two objects depends on the relative scattering power as distinct from the support if any

If it were possible to produce electron images free from spherical and 'chromatic' aberration the only factor controlling the resolving limit would apparently be the wave length of the de Broglie waves Assuming the aperture of the corrected lens to be 0 1, a limit of less than 10^{-7} cm might apparently be attained Apart from the questions raised above there are however, serious difficulties It does not seem possible to secure 'achromatism' of the electron lenses, and the only alternative is to make the incident radiation as homogeneous in velocity as possible Various factors require a voltage of 50,000 or more, and it is difficult to maintain a perfectly steady electrical pressure of this magnitude The usual circuits employ a transformer with valves to produce half-wave or full-wave rectification, together with as large a reservoir condenser as possible The residual ripple can be reduced to one tenth of one per cent without undue trouble, and may be further reduced by filters

When cold cathode discharges are used, the current can be stabilized by a saturated diode valve, and the inhomogeneity is reduced to that caused by collision effects, etc , in the discharge tube supplying the electron stream In all cases the perfection of the vacuum technique is essential, and conditions of the utmost constancy must be obtained If necessary complete stabilization of the supply for hot cathode work can be attained by the use of a battery but the high initial cost maintenance and rapid depreciation of such a battery present difficulties which will be well understood

Assuming that the voltage spread can be sufficiently reduced the question of the spherical aberration of the lenses comes into prominence It is apparently not possible to design magnetic or electrostatic lenses which are free from this defect and no known arrangement seems to do more than approach a certain minimum value This question has been studied theoretically by Scherzer and also on the basis of numerical calculations by Rebsch who reaches the conclusion that the limit of resolving power of electron optical systems will always be set in this way at about ten to one hundred times the electron wave length instead of going below the wave length itself as might be inferred from Abbe s optical formula Whether or not this conclusion is just the implied limitation does not exclude the possibility of opening up still further new fields in high power microscopy

Just as in ordinary optics however where more than half the serious troubles are due to faulty construction and lack of symmetry of the parts the electron microscope is by no means easy to perfect in such respects In the first place the present instruments are given a length of about two metres in order to reach the required magnification in two stages and moreover a complicated object holder chamber and adjustable coils have to be included in the apparatus It is thus scarcely practicable to secure a geometrical symmetry by merely screwing together a set of lathe turned parts as is done in the telescope Even if this were done the electron beam would still be appreciably curved unless the axis of symmetry coincided with the direction of the earth s magnetic field Again it is by no means easy to make an ironclad magnetic coil truly symmetrical in the magnetic sense about its mechanical axis The residual irregularities in the winding and probably especially the variation of magnetic resistance in the gaps of the soft iron sheathing produce a lack of symmetry in the field even more troublesome is the fact that the asymmetry varies with the varying current especially when the magnetism of the sheath is approaching saturation The perfection of such coils is an interesting problem

For a number of reasons therefore the early instruments were built up with components arranged as symmetrically as possible and the beam was sometimes persuaded along its required path by judicious use of bar magnets ! In the instrument described by Martin Whelpton and Parnum the necessary control was obtained in a less objectionable way by the use of paired coils in the Helmholtz manner This instrument in use at the Imperial College is now so arranged that the objective coil can be adjusted both in tilt and lateral position and further the condenser and projection coils can be adjusted laterally all from outside the vacuum

Neglecting the residual asymmetry of a coil which is not after all very large the system of initial adjustment depends on the fact that if any object is not on the axis of a coil the image will move in a radial direction around the axis when the current in the coil is varied The finer centring adjustments may require the deliberate use of inhomogeneity in the beam velocities Failing perfect centration very serious aberrations in the image will correspond to lateral chromatic spreading of the image points and coma even in the centre of the picture

A major part of the experimental work at the Imperial College has been devoted to a study of the optical adjustments of the system in the above sense and it is hoped that when more perfect electrical equipment is available the experience thus gained will make it possible to obtain the optimum results

A word may be added as to the relations of the electron microscope to the research methods of X ray and electron diffraction analysis It is true that where some degree of regularity exists in the structure of matter these powerful and beautiful methods can be used with confidence to elucidate the atomic pattern just as diffraction spectra appearing in the optical microscope may prove the existence of a structure which still cannot be resolved by the instrument It is the possibility that the electron microscope may prove a means of examining irregularities and discontinuities in structures which makes it seem so promising even if the method cannot deal with elements so small as those of crystal lattices

On the analogy of the Abbe principle it may be said that if the aperture and corrections of the lenses could be so far improved as to include the electron diffraction maxima from a crystalline structure without incurring appreciable aberration the very elements of the lattice would be resolved in the picture That achievement may at present be quite outside the limits of apparent probability but the subject is still in its infancy and at a stage corresponding to the period in the history of the optical microscope before the achromatic lens was invented We may learn from the experience of those days not to be over confident in setting limitations to what is possible

Obituary Notices

Sir Thomas Callender

SIR THOMAS OCTAVIUS CALLENDER who died at his home at Bidborough Court Kent on December 2 at the age of eighty two years spent a long and very busy life in promoting the electrical industry He was the eldest son of the late W O Callender of Bournemouth and was born in Glasgow in April 1855 He was educated at Greenock in London and later at Boulogne sur Mer The outbreak of the Franco Prussian War made it necessary for him to leave France and later he entered his father s office in London devoting himself to the asphalt paving and bitumen refining business of which W O Callender was founder Having acquired an interest in part of the Trinidad Lake W O Callender and two of his sons founded the business of Callender and Sons in 1877 for the supply of Trinidad bitumen Large quantities of bitumen were refined and used for road making and building purposes but it was felt that further developments were possible and its uses for electrical work were constantly considered

When Callenders started carrying out complete contracts for both the making and laying of underground mains their practical knowledge of road making proved of great value In the early days, the only output for insulated wires was in connexion with the electric telegraph When Edison and Swan brought into practical use the electric glow lamp it became clear that some materials such as Callenders were making could be usefully employed for the heavy mains which would evidently be required Bitumen in its natural state was useless as it is easily affected by heat and consequently unstable After many experiments it was discovered that a combination of certain palm oil residues with bitumen produced a material that could be vulcanized and so could be employed as a covering for both heavy electric cables and light electric telegraph wires For this experimental work Letters Patent (No 4409) were granted to Mr W O Callender in October 1881 Mr Tom Callender was elected manager of Callender s Bitumen Telegraph and Waterproof Company formed to develop this discovery Sir Samuel Canning (who with Lord Kelvin was famous for his Atlantic cable experience) was appointed consulting engineer to the company

In 1894 the directors were able to report that out of eighty two electric light stations then in existence or under construction in Great Britain their Company had supplied mains to thirty eight In July 1896 Callender s Cable and Construction Co was formed and took over the entire interests and contracts of the old company Mr Tom Callender was appointed managing director and controlled the business with conspicuous success almost up to the day of his death

Tom Callender was a great traveller Shortly after he joined his father s paving and bitumen business he spent nearly a year in Rumania repaving the entire city of Jassy His journey to St Petersburg in 1880 concentrated his interest in electrical work The illumination produced by an immense number of Jablochkoff candles at the Opera House astounded him Three years later Callenders installed the necessary underground mains when Covent Garden Opera House London was electrically illuminated On a later occasion he went to the United States by the Cunard S S *Scythia* which was lighted by paraffin lamps and returned by the Cunard S S *Servia* the first large liner to be equipped with an effective electrical installation He was so impressed that on his return he urged his company to devote all possible attention to electrical development In 1930 Callenders acquired a new research laboratory in which is installed the most modern electro technical apparatus It is mainly employed in performing experiments with the object of elucidating the trend of future evolution in the cable industry In opening it Lord Rutherford made a very appreciative speech on the work it was doing under the superintendence of Mr P V Hunter

Tom Callender married in 1885 Bessie the eldest daughter of Mr William Pinnock of Belvedere Kent, and had one son Mr T O Callender who has been a director of the present company since 1932 The controlling genius of the extensive Callender interests was honoured by knighthood in June 1918 This well deserved recognition gave the greatest pleasure both to the numerous friends of Sir Thomas and Lady Callender and also to the company s large staff in all parts of the world The company published a memorial volume The Story of Callender s 1882 1932 to celebrate its fiftieth anniversary It gives biographical sketches of all the distinguished members of the staff and also an account with photographs of the works the company has done and is doing in almost every part of the world Among them are Windsor Castle (1907) Keble College Oxford (1909) Birmingham (1890) Bombay (1908) Agra (1924) Hong Kong (1904) the City and South London Railway (1889) and Banhida Hungary (1928)

A R

Prof J W Bews

J W BEWS was born at Kirkwall, in the Orkney Islands, in 1884 being the younger son of the late James Bews, of Berry Hill Scapa Orkney From the Kirkwall Burgh School he entered the University of Edinburgh as Earl of Zetland bursar in 1902 After graduating he was appointed lecturer in economic botany in the University of Manchester, but returned to Edinburgh in 1908 as lecturer in plant physiology and assistant professor of botany

In 1910 Bews was appointed professor of botany in the Natal University College with which he has since been associated except for the period 1925–27, when he occupied the chair of botany at Armstrong College, University of Durham

As soon as Prof Bews arrived in Natal he began his investigations of the vegetation and within a short period had published a number of important papers on the plant ecology of Natal and of South Africa He was a pioneer of plant ecology in South Africa, and in addition to making many important contributions to the science of ecology, his work has had an important bearing on many economic questions, such as soil erosion veld burning, over grazing afforestation and weed control In particular, his work on the grasses and grasslands of South Africa has stimulated much research which is now being carried out in various parts of the country, and is producing many important changes in some aspects of agricultural practice

In 1921 Bews completed a Flora of Natal and Zululand , and later investigated the origin, evolution and migrations of the South African flora After publishing several papers on this subject he issued his conclusions in a more extended form in a book on 'Plant Forms in 1925 This led naturally to a wider study of the classification and evolution of plant growth forms and the results were summarized in another book on The Ecological Evolution of Angiosperms

During his short but successful, stay at Armstrong College, Newcastle upon Tyne Prof Bews worked assiduously at the grasses, with the result that in 1929 his World's Grasses' was published This important work is accepted as standard throughout the British Empire and the United States

In 1930 Prof Bews was appointed first principal of the Natal University College and has been responsible for organizing and guiding the recent rapid developments which university work in Natal has undergone and for laying the foundations of the future University of Natal During this period in spite of heavy administrative responsibilities he found time to apply himself to a study of man and some of the problems confronting mankind He approached these also from the ecological point of view and wrote two books on the subject— Human Ecology published in 1935 and Life as a Whole in 1937 His synthetic approach to these problems was along new lines, and he considered these books merely as a preliminary survey of the field In addition to his scientific research work, which is contained in numerous published papers, as well as in his books, Prof Bews built up a strong department of botany at the Natal University College, and achieved much success both as a teacher and as a director of student research

Prof Bews occupied an important and prominent place in the administration of university and scientific affairs in South Africa He was a member of the Council of the University of the Cape of Good Hope, and of the University of South Africa several times chairman of Senate of the University of South Africa, and a fellow of the Royal Society of South Africa. In 1931, he was president of the South African Association for the Advancement of Science, and in 1932 was the recipient of the South African Medal, which is the Association's premier award In 1932 he was also one of a small deputation of eminent men of science chosen to represent South Africa at the centenary meeting of the British Association

Great as Prof Bews was as a scientist and administrator, he was equally successful in attracting a circle of appreciative friends both in South Africa and at home He was only two years with us in Newcastle yet those of us who were fortunate enough to gain his friendship will never forget it or the genial placidity with which he confidently faced all difficulties

We all feel the better for having enjoyed the privilege of knowing him

J W HESLOP HARRISON

Mr J J Kneen

We regret to record the death of Mr J J Kneen distinguished as an authority on the antiquities and language of the Isle of Man which took place on November 21 at the age of sixty six years

John Joseph Kneen was born on September 12 1872, and educated at St George's School Douglas Isle of Man His lifelong devotion to Manx studies received recognition not only within the island but also from outside He was past president and secretary of the Manx Society which exists for the preservation of the language literature and music of the Isle of Man and a member of the executive of the World Manx Association for the federation of Manx people throughout the world, as well as of the Manx National Assembly In 1930–31 he was president of the Manx Natural History and Antiquarian Society The University of Liverpool conferred upon him the honorary degree of M A in 1929 , and four years later he was made Ridder of the First Class of the Order of St Olaf of Norway His most signal distinction however was a grant of £200 from the trustees of the Fridtjof Nansen Fund to the trustees of the Manx Museum and Ancient Monuments for the purpose of enabling him to continue his researches on Manx place names and more especially of recording the true local pronunciation of these names before precise knowledge of the Manx tongue had died away

We regret to announce the following deaths

Andre Blondel since 1913 a free member of the Paris Academy of Sciences and a distinguished electrical engineer known for his work on alternating current theory and for the development of the oscillograph and of the radio beacon on November 15, aged seventy five years

The Right Hon Lord Chalmers, Governor of Ceylon from 1913 until 1916, a trustee of the British Museum during 1924–31, and president of the Asiatic Society during 1922–25, on November 18 aged eighty years

Dr F W Goodbody, lecturer in medical chemistry in University College, London on November 30, aged sixty eight years

Sir Brajendranath Seal, formerly vice chancellor of the University of Mysore, known for his work in education and Bengali philosophy, on December 3, aged seventy four years

News and Views

Pilgrim Trust Lecture

THE first Pilgrim Trust Lecture was delivered on December 8 before the Royal Society meeting in the historic lecture theatre of the Royal Institution by Dr Irving Langmuir of the Research Laboratories of the General Electric Company Schenectady N Y A brief account of the substance of the lecture appears on p 1085 It will be recalled that the announcement of the institution of this lecture was made by Sir William Bragg in his presidential address last year to the Royal Society The scheme for the lectures was drawn up by the Royal Society and the U S National Academy of Sciences and the Pilgrim Trust very generously agreed to provide an honorarium of 250 guineas a year for six years The lectures are to be delivered in alternate years in London and Washington by an American and a British man of science respectively Sir William Bragg suggested when referring to the lectures that they might be used to transmit new ideas which have begun to bear useful fruit and give promise of wide expansion, rather than to record past achievements and Dr Langmuir's choice of subject and his method of handling it must have been gratifying to Sir William Dr Langmuir himself must be congratulated on giving a most inspiring lecture on a difficult subject and on the fact that he had the courage to begin with the very elementary facts Thus the first link in another chain binding together the peoples of Great Britain and the United States has been well forged and it should not be impossible to find means to make the lecture a permanent institution Such international contacts are of vital importance in these days of strife and world unrest and every effort should be made to promote active co-operation between the scientific workers of different countries It is much to be hoped that the approach made by Dr Bosch president of the Kaiser Wilhelm Gesellschaft to the Royal Society, which was referred to by Sir William Bragg in his presidential address on November 30 last may be the beginning of yet another of these international bonds

Prof J W Cobb, C B E

PROF J W COBB retired recently from the Livesey professorship of coal gas and fuel industries in the University of Leeds—a chair which he had held since 1912, shortly after its foundation, when it was the only university chair in fuel technology in Great Britain In response to a circular of appeal, a sum of about £850 has been contributed to signalize his services to the University and to industry, notably the British gas industry Of this sum £583 was contributed through the Institution of Gas Engineers On December 9, at the University of Leeds, with Major G H Kitson in the chair, certain presentations were made and the balance—£750 was presented to the University of Leeds In accordance with the wishes of Prof Cobb it is proposed that the income from it be used to assist students of the Department of Coal Gas and Fuel Industries with Metallurgy to meet the cost of maintenance while at the University or to cover other expenditure necessary for their studies or researches Mr R Robertson president of the Institution of Gas Engineers said Prof Cobb is held in the highest esteem by everyone in the gas industry He is already an honorary member of the Institution of Gas Engineers but from now on he can regard himself as an honorary member of the gas industry at large Mr H J Hodsman speaking for the Department said that nowadays fuel research is a comparatively fashionable branch of science, but when Prof Cobb arrived in 1912 the Department was the only one of its kind in the country and it had very few students Its present position was therefore a measure of Prof Cobb's achievements Prof J H Priestley and the Vice Chancellor also added their praises of Prof Cobb and his work for the University

Wladimir Markownikoff (1838 1904)

ON December 22 occurs the centenary of the birth of the Russian chemist Wladimir Markownikoff whose investigations in the latter part of last century were of great importance to the petroleum industry He was born in the neighbourhood of Nijni Novgorod and was a student at the University of Kasan where he came into contact with Alexander Mikhailovitch Butlerow (1828 1886) whom he succeeded in 1869 when the latter had been transferred to the chair of chemistry in the University of St Petersburg Meanwhile Markownikoff had been sent to Germany, where he worked under Kopp Baeyer and Kolbe After his return to Kasan he published his memoir Ueber die reciproke Beeinflussung der Atome im Molecule In 1871, with five colleagues he resigned his post for political reasons but received an invitation to the chair of chemistry at Odessa whence he was transferred to Moscow in 1873 Here he began his long and arduous investigations of Caucasian petroleum In 1893 without any reason being assigned he was deprived of his chair, his emoluments and his official residence, but nevertheless he continued to carry on his researches in his own house, assisted by his faithful servant Mikhailo He died suddenly on February 11, 1904 He wrote some sixty memoirs relating to petroleum, army disinfection practice, the plague and the chemical industry in Russia In 1898 he was elected a foreign member of the Chemical Society, in the *Proceedings* of which E J Mills wrote of him as a conscientious man of science of unremitting industry, and in political affairs an outspoken patriot

Queen Mary College

QUEEN MARY COLLEGE celebrated this week the anniversary of the presentation of a Royal Charter to the College by Her Majesty Queen Mary the Patron of the College on December 12 1934 The proceedings culminated in a reception on the evening of December 16 when the principal of the College Prof G M Bennett, Prof J T MacGregor Morris Miss Florence Rich and Sir John Russell are being admitted as fellows of the College The College which owes so much to the insight and wise guidance of its late principal Mr J L S Hatton and its present principal Sir Frederick Maurice occupies a unique position in the scheme of the University of London Situated a mile and a half east of Aldgate Pump, it provides a university course of training for students drawn in the main from the population of Essex and Middlesex but not from these regions only for within its walls are to be found students coming from all parts of Great Britain and of the Empire

QUEEN MARY COLLEGE which has grown steadily from a small beginning as the Technical School of the People's Palace has for some time past realized the urgent need for the extension of the housing of its Faculties of Art Science and Engineering and for the provision of hostels and athletic grounds for its students It has courageously embarked on a building scheme under which the Engineering Departments the Chemistry Department the Aeronautical Department and the Botany Geology and Geography Departments have been extended or reconstructed new Zoology and Arts Departments have been built and a high voltage laboratory the first of its kind in London has been equipped The cost of this completed portion of the programme is some £118 000 of which £113 000 has been received or promised A great deal however remains to be accomplished and the College is now considering the building of a college hall dining hall and kitchens the reconstruction of the Students Union rooms the rehousing of the administrative offices and an urgently needed extension of the Physics Department The cost of this last part of the building scheme is estimated at £125,000 and all interested in college and university life in London will wish the Governors of Queen Mary College an early success in their attempt to provide a college which shall in its material equipment be worthy of the traditions which it has established in its thirty one years of life as a School of the University of London

Birkbeck College

BIRKBECK COLLEGE, University of London celebrated on December 7 its 115th anniversary with an eloquent oration on Ends and Means by Sir Richard Livingstone, president of Corpus Christi College Oxford The Foundation oration dealt with the underlying principles of morality in individual and social intercourse in contrast with the present unrest in world affairs In his report, which was followed by the presentation of graduates, Dr George Senter, principal of the College, mentioned various details about its progress the plan for moving it to the Bloomsbury site the distinctions gained by the staff and the activities of the various College societies During the last academic year there were 971 students registered 122 having graduated Statistics show that 430 students were teachers 176 clerks and 132 chemists Considerable progress was made during the year with the plans for new College buildings on the Bloomsbury site Towards the end of the session instructions were given for the clearance of the site and it was expected that the detailed plans would be submitted soon to the Governors A notable appointment to the academic staff was that of Prof J D Bernal who succeeded Prof P M S Blackett in the chair of physics Prof Bernal's work is mainly concerned with structural investigations by means of X rays and is of great interest to chemists and biologists as well as to physicists

German Native Policy and Racial Theory

DISCUSSION of German colonial claims will be clarified by a statement of the policy which would be applied in native administration under racial doctrine appearing in an official publication of the National Socialist Party The Colonial Question and Racial Thought by Dr Gunther Hecht an expert of the party on racial problems As might be anticipated the principle of segregation it would appear from a summary of the provisions by the Berlin correspondent of *The Times* in the issue of December 12 is to be applied stringently and any attempt to Europeanize or divorce the native from his culture is abrogated he will neither be baptized nor will his equality with Europeans be preached No native will be allowed to leave the German colonies for Europe as either servant worker soldier or student but on the other hand coloured people will be allowed their full rights of existence in their own homeland and no more will be demanded from them than they can achieve No native will be allowed to become a German citizen but they will nevertheless possess more rights than have been merely promised to them in other colonies No European matter will be taught in native schools lest Europe should be presented to them as the peak of cultural development and they should lose faith in their own powers Local culture therefore will be fostered but side by side with it there will be an introduction to an understanding of European civilization In principle higher schools and universities will be closed to natives Without entering into extended comment on the principles of this policy beyond noting a commendable adherence to the development of the native through his own culture it may be questioned what opportunities will be afforded for development towards that self determination however remote it may be and whatever its form which has been formulated as the end of native administration under mandatory policy

Systematics in General Biology

THE annual general meeting of the Association for the Study of Systematics in General Biology was held in the rooms of the Linnean Society, Burlington

House, Piccadilly, London, on December 15 The inaugural meeting of this newly established association was referred to in NATURE of July 24, 1937, p. 163. At its inception, 53 biologists joined the Association, and since then the membership has increased to 162 The aims of the Association, among others, are to study the bases and practical aims of taxonomy, to examine criteria employed in defining species and other systematic categories; to consider any modification of existing classification in the light of cytogenetic, ecological, physiological, embryological, biochemical and palæontological data, to press for increased attention to taxonomy in museums and other institutions, to organize research, to aid the production of handbooks on British animals and plants, and eventually to produce a British Fauna and Flora on uniform biological lines, to investigate methods of teaching systematics, to promote co-operation between workers in different branches of biology on problems of taxonomic interest The Taxonomic Principles Committee has already considered several important problems, and has decided to prepare an index of all terms which have been used to designate groups below the rank of species This should prove of value, especially to young research workers in taxonomy The Committee on Comparative Systematics has examined the sources from which data for research on variability and other problems may be drawn The Research Committee has initiated or assisted in the launching of twelve lines of research, and a list of institutions where such work may be done has been prepared Work has been started on a book on the anatomy of Dicotyledons. The Committee on Handbooks is now compiling a review of existing taxonomic literature on the British flora and fauna The provision of a check list of the British flora and fauna is being dealt with in collaboration with the Association of British Zoologists. Cheap systematic handbooks are also being considered

THE Committee for Co-ordinating the Work of Natural History Societies has been aided in its exacting task by the British Association The pioneer work of these various committees is commendable, and all biologists, whether directly interested in systematics or not, will be grateful for the results of their work Various publications, such as articles in NATURE and *Chronica Botanica*, have been sponsored by the Association, and others are projected Discussions and symposia on taxonomic subjects have been supported by the Association at meetings of the British Association and of the Linnean, Zoological and Genetical Societies The Association has no constitution yet, but it has since worked with enthusiasm It is considered that with a minimum membership of five hundred, each member paying the modest sum of £1 for life-membership, the Association could achieve all its aims. We hope that this enrolment will be achieved and even exceeded, for the Association has, in a very short time, showed that it is providing an essential service to biology, and considering its present projects, its usefulness will certainly continue to increase. Not only specialized systematists but also all other biologists would prove useful to this Association, which clearly deserves all the support it can get Information concerning the Association can be obtained from either Mr J. S L Gilmour, Royal Botanic Gardens, Kew, Surrey, or Mr. H W. Parker, British Museum (Natural History), South Kensington, London, S W 7

Palæolithic Finds in Bulgaria

DR DOROTHY GARROD's account of her recent excavation of the cave of Batcho Kiro, near Drevono, in Bulgaria, given before the Society of Antiquaries of London on December 8, adds a link of no little importance to the chain of evidence of the distribution of cultures of the later periods of the palæolithic age in eastern Europe and adjacent regions Dr Garrod's excavations were carried out in the summer of 1938, when she had the assistance of Mr James Gaul and Mr Bruce Howe of Harvard University, by permission of the Bulgarian Government and with the co-operation of the National Museum of Sophia The cave is very large with an intricate system of corridors running at least a kilometre into the rock Flint implements had already been discovered here in association with bones of the cave bear by a local engineer The present excavations were confined in the main to the principal chamber; and here for the first time in Bulgaria a stratified sequence of palæolithic deposits has been found At the bottom of the section was a Mousterian level, in which the implements were made chiefly from pebbles of volcanic rock from a stream near by. Above this level were layers of deposits belonging to the Upper Palæolithic, in which the industries were more or less of Aurignacian type, and the implements were made of flint They were associated with animal bones, among which were cave bear, cave hyena, and in the lowest levels woolly rhinoceros These levels, corresponding to others of the same kind in other parts of Europe, are to be assigned to the last stage of the Quaternary Ice Age

Prehistoric "Harpoon" from Scotland

A REMARKABLE barbed point of red deer antler found in the bed of the River Irvine below Shewalton Sands, Ayrshire, was described by Mr A. D Lacaille at a meeting of the Society of Antiquaries of Scotland in Edinburgh on December 12. The point, which may have been part of a harpoon or multi-pronged fish-spear, is believed to be the largest prehistoric point of its kind as yet recorded in the British Isles It measures 7⅜ inches long, and is rhombic in section It has five pairs of barbs. A groove appears on each side of a pronounced mid-rib at the tip. It has been skilfully fashioned, evidently by stone tools The dating of the point is uncertain; but it is conjectured that it was made by settlers on Shewalton Moor, a locality rich in prehistoric and other antiquities Both its form in section and the grooves mark a considerable technical advance on the Azilian type of barbed harpoon. Nevertheless, the Shewalton point, it is indicated, bears a general resemblance to the harpoons of antler and bone previously found in Scotland at Oban, Oronsay and Kirkcudbright The present find is figured in *The Times* of December 13

Indian Cultural Studies at Oxford

WHILE the range and character of the collections of the India Museum at South Kensington will always give London a predominant position as a centre of Indian cultural studies, it should not be overlooked that the University of Oxford is not unconscious of its obligations in this direction The report of the curators of the Indian Institute for the academic year 1937–38 states that during this period the museum has undergone a much needed reorganization, thanks to a substantial grant from the Max Muller Memorial Fund and a generous gift from Mr and Mrs Spalding The aim of the reorganization is not only to raise the character of the exhibits, but also to serve the needs of the studies carried on in the Institute, and more especially to stimulate interest in the antiquities and art of India Among gifts and bequests, upon which the museum has to rely to a large extent, recent additions include a Buddhist shrine on loan from Mrs Alexander Scott, which shows excellent specimens of the work of Newari and Tibetan artists, while Dr Stella Kramrisch has lent a valuable collection of Hindu sculpture Some interesting terra cottas have come from the Royal Asiatic Society, and a collection of Siamese sculpture, the property of Dr Reginald Le May, is especially instructive as a demonstration of the influence of Indian art and civilization on south eastern Asia Further facilities for the study of the cultural relations of south eastern Asia will also be afforded members of the University by the valuable collection of Malayan books formed by Mr W W Skeat, author of ' Malay Magic ' and, with Dr C Otto Blagdon, of Pagan Tribes of the Malay Peninsula This collection has been accepted by the University as a gift from Captain W Ogilvy by whom they were purchased for that purpose Volumes additional to those purchased have been added by Mr Skeat in order to enhance the value of the collection for anthropological students

Cultivation of Plants without Soil

FOR many years it has been known that plants can be grown in nutrient solution culture, without soil, provided that the medium contains the necessary elements for growth in sufficient quantity While this method is widely used in teaching and research work, it is only recently that attempts have been made to utilize it on the commercial scale, the idea originating in the United States Considerable interest has been aroused by the apparent success of the methods employed in the United States, and an account of their four chief methods, namely, (1) solution culture, (2) sand culture, (3) sub irrigation, and (4) drip culture, is given in the November issue of the *Journal of the Ministry of Agriculture* Experiments carried out at the Jealott's Hill Research Station to determine the results of such methods under English conditions are also described These latter tests were confined to tomatoes, and showed that some varieties are more suited to solution culture than others There is as yet no proof that yields are as good as those obtained under the best soil conditions but it must be borne in mind that the method, as a commercial system, is still in its infancy Advantages claimed for the method are the elimination of soil borne diseases, the greater control over the type and amount of growth by judicious regulation of the culture medium and reduction in manual labour However the cost of equipment is a heavy item and the technique is not yet fully worked out The experiments are to be continued, the work being extended to other crops The results will be awaited with interest

Smithsonian Institution Anthropological Publications

A NEW departure in publication is a series of Anthropological Papers consisting of articles less extended in length than the usual report on the explorations of the Smithsonian Institution which will be numbered consecutively and will be collected from time to time in bulletin form as occasion requires The first issue (*Bull* 119 , 1938) contains six articles of which the first and most considerable is a preliminary report by Mr A R Kelly on the first four seasons work of excavation on mound sites in the Ocmulgee Basin near Macon, Georgia These excavations were undertaken originally as a measure of unemployment relief under the Civil Works Administration The site has yielded an unanticipated wealth of material, and exploration is still in progress Cultural development here appears so far as present knowledge goes to be of an extremely localized type, in which a pottery of characteristically primitive appearance is associated with an unusual type of underground house and early evidence of agriculture Whether this represents an archaic horizon in the south east is a moot question , but at several points it exhibits generalized resemblances with regions geographically so far distant as the Great Plains and the south west The remaining papers deal with a pipe ceremonial of the Arapahoes (Mr John M Carter), the Caribs of Dominica (Mr Douglas Taylor), a Sauk sacred pack (Mr Truman Michelson), the physical therapy of Soshoni of Idaho upon which Mr Julian H Steward reports, and a biographical account of an Owens Valley Paiute by the same author

Scientific Publications in Japan

A THIRD edition of a Catalogue of Foreign Scientific Serial Publications in the Various Institutions in Japan has just been published by the National Research Council of the Department of Education, Tokyo The general arrangement of the work is very similar to most Union catalogues, except that whilst other publications give the holdings of each institution and an abbreviation to denote if a set is imperfect, this volume gives full particulars of the actual parts, volumes or years lacking This feature should be of considerable service to Japanese research workers by saving them fruitless journeys, particularly as the large number of imperfections listed suggests that the proportion of incomplete series is somewhat high While the method of alphabetization adopted is strictly correct it may prove in practice to be less convenient than the catchword method used in the World List as a research worker frequently depends upon short abbreviations and is unacquainted with unimportant particles on which the alphabetical order depends In addition the adoption of a strict alphabetical sequence tends to separate periodicals dealing with the same subject which a catchword method tends to bring together The volume is well printed in a clear type and although the titles of the periodicals are all in languages foreign to the place of publication the work is remarkably free from printer's errors This catalogue affords evidence of Japanese enterprise in the field of bibliography and it is obvious that very considerable care has been taken in its compilation It should be of much value to scientific workers resident in Japan

The Industrial Health Research Board

THE eighteenth annual report of the Industrial Health Research Board up to June 1938 (H M Stationery Office 1s net) contains a summary of the results of twenty years work and describes the work of the current year During its twenty years of activity an attempt has been made to discover new ways and means of improving working conditions in factories and workshops, and the results of shortening the hours of labour of splitting up shifts and of introducing rest pauses have been studied and the influence of environmental conditions and methods of work upon the output and the health of the workers has been investigated During the present year the Board has investigated the relation between illumination and industrial efficiency problems of noise and deafness dust and ill health toxic solvents, work at high temperatures and ventilation Vocational psychology applied to vocational selection and guidance in industry vocational tests for skilled and unskilled occupations and tests of accident proneness are other subjects to which considerable attention is now being directed

Principal Earthquakes during 1937

IN 1937 there were no really great earthquakes but damage was done by eight shocks and several others were felt by human beings in various parts of the world The eight which did damage were Guelma (Algeria) February 10 Rabaul 4° 10 S 152° 10 E (New Britain) May 28, Maltrata (Mexico), July 26 Tsao Tchéou (China), August 1, Manila (Philippines) August 20, Samarang (Java) September 27, Mexico City, December 23, and Oxapampa (Peru) December 29 These and others are discussed by Prof J P Rothé, of Strasbourg, in *Revue pour l'Étude des Calamités*, 1, No 2, 1938 under six regional headings continent of Europe, Mediterranean region, continent of Asia, Asiatic islands and circum Pacific coastlines the American continent and the African continent with Madagascar It is noteworthy that no disastrous earthquake was felt in Europe, and the only one reported from Britain was near Birmingham

The Philosophical Society

THE Philosophical Society of England celebrated its silver jubilee on December 7 with a luncheon at St Ermin's Restaurant London and a lecture by the Rev I Hartill a vice president of the Society, on John Milton Various speakers emphasized the useful purpose of the Society its steady development and its practical achievements Messages were sent by the American Ambassador Lord Gorell and Prof A I Heath who were unable to attend This Society was founded in 1913 by a group of persons interested in the moral sciences with the view of promoting the study of philosophy among the general public The Society publishes the *Philosopher* holds meetings and organizes lectures from time to time Also it encourages the formation of local centres and study circles and the introduction of matters of philosophical interest in schools and other educational institutions Its vice presidents include many distinguished philosophers and a number of eminent scholars from abroad are among its honorary fellows

Sir George Beilby Memorial Awards

THE administrators of the Beilby Memorial Fund —the presidents treasurers and secretaries of the Institute of Chemistry the Society of Chemical Industry and the Institute of Metals respectively—have awarded one hundred guineas each to Dr F P Bowden and Dr Brynmor Jones Dr Bowden was educated at the Hutchins School Hobart and at the University of Tasmania He went to Cambridge in 1927 entered Gonville and Caius College and continued electrochemical work in the laboratory of physical chemistry with Prof F K Rideal and Prof T M Lowry In 1931 he was elected to a research fellowship at Caius College and was appointed University demonstrator in chemistry In 1937 he was appointed to the Humphrey Owen Jones lectureship in physical chemistry His electrochemical work has been mainly on over potential and the mechanism of electro deposition His other work on the physical properties of surfaces has an important bearing on the problems of friction, lubrication and wear Dr B Jones studied metallurgy during 1919–22 at University College, Cardiff under Prof A E Read From 1927 until 1929 he was attached to the Metallurgical Branch of the Research Department of Woolwich Arsenal, and afterwards was appointed lecturer in metallurgy at University College, Cardiff Dr Jones has devised many methods in metallurgical analyses His outstanding published work has been on the subject of the nitrogen hardening and on the heat treatment of steels, which has been appearing in the *Transactions of the Iron and Steel Institute*

Physical Society's Annual Meeting

THE twenty ninth annual exhibition of scientific instruments and apparatus, arranged by the Physical Society, will be held at the Imperial College of Science and Technology, Imperial Institute Road, South Kensington, S W 7, on January 3–5 The leading manufacturers of scientific instruments will be exhibiting their latest products in the Trade Section The Research and Educational Section will contain contributions from research laboratories, and experiments of educational interest In addition, the work submitted for the Craftsmanship and Draughtsmanship Competition by apprentices and learners will be on view Discourses will be delivered at 7 45 on January 3 by Dr J D Cockcroft, on The Cyclotron and its Applications", and on January 4 by Mr C S Wright, on "Geophysical Research in Polar Regions Admission to the exhibition is by ticket only, obtainable from scientific societies or direct from the Exhibition Secretary, 1 Lowther Gardens, Exhibition Road, S W 7

British Association. Dundee Meeting

The annual meeting of the British Association will be held next year in Dundee from August 30 until September 6 under the presidency of Sir Albert Seward The following sectional presidents have been appointed Section A (Mathematical and Physical Sciences), Mr R S Whipple, Section B (Chemistry), Prof E K Rideal, Section C (Geology), Prof H H Read, Section D (Zoology), Prof J Ritchie, Section E (Geography), Mr A Stevens, Section F (Economics), Prof H O Meredith, Section G (Engineering), Mr H F Wimperis, Section H (Anthropology), Prof W E Le Gros Clark, Section I (Physiology), Prof D Burns, Section J (Psychology), Mr R J Bartlett, Section K (Botany), Prof D Thoday, Section L (Education), Dr A P M Fleming, Section M (Agriculture) Sir Thomas Middleton

Colonial Service Appointments

The following appointments and promotions in the Colonial Service have recently been made J E R Roe, veterinary officer Uganda, T Bell (Government Stock Farm and Agricultural Station, Acre, Palestine), agricultural superintendent, British Guiana, W A Gordon (assistant conservator of forests, Gold Coast), assistant conservator of forests, Cyprus, G W St Clair Thompson (assistant conservator of forests, Gold Coast), assistant conservator of forests, Uganda, J H Gibbons (chief inspector of mines, Northern Rhodesia), senior inspector of mines, Tanganyika Territory, K E Lee (assistant inspector of mines, Uganda), inspector of mines, Federated Malay States, L Humphrey (supervisor of physical training, Sierra Leone), meteorological assistant, Nigeria

Announcements

Sir John Forsdyke, director and principal librarian of the British Museum, and Mr John L Kirk, honorary director of the Castle Museum, York, have recently been elected honorary members of the Yorkshire Philosophical Society, York

At a reception on December 6 at the Belgian Embassy, Baron de Cartier de Marchienne, the Ambassador, presented a number of bronze medals awarded by King Leopold of the Belgians to various British scientific workers The medals, bearing on one side the head of King Leopold and on the other the name of the recipient, and the occasion of the award, were a token of appreciation for the help given by the various specialists in classifying the natural history collections which the King of the Belgians made in 1928–29 during his voyage to the East The recipients, most of whom were present at the Embassy, were Sir Guy Marshall, Dr K Jordan, Dr Isabella Gordon, Dr S Maulik, Dr W H Leigh Sharpe, Miss G Ricardo, Mr C L Collenette, Mrs L M I Macfadyn, Mr W H T Tams, Mr H E Andrewes, Miss I Meyrick (for her late father, Mr E Meyrick), Prof H Gordon Jackson, Dr H Hanitsch Mr C J Arrow, Dr Evelyn Cheesman, Dr Marie V Lebour, Dr Schwarz Mr L B Prout, Mr A J T Janse and Lieut Colonel F C Fraser

Dr Irving Langmuir will deliver an address before the Physical Society on December 20 at 5 15 The subject of Dr Langmuir's address will be "The Structure of Proteins'

An industrial fellowship has been established in the Mellon Institute, Pittsburgh by the American Air Filter Company, Inc, of Louisville Ky This fellowship will aid investigations on materials of value in the construction of filters for air conditioning systems Dr Frank F Rupert, who has been appointed to the fellowship, has been a member of the Mellon Institute since 1913 Since 1935 he has been associated with the fellowship on air hygiene in the Institute

Under the terms of administration of the Clough Memorial Research Fund of the Edinburgh Geological Society a sum of approximately £30 is available annually for the purpose of encouraging geological research in Scotland and the north of England The north of England is defined as comprising the counties of Northumberland Cumberland, Durham, Westmorland and Yorkshire Applications for grants are invited for the period April 1, 1939–March 31, 1940, and should reach the Secretary, Clough Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh, not later than February 1, 1939

The fourth Oxford Farming Conference will be held at Oxford on January 3–5, under the auspices of the School of Rural Economy, the Agricultural Economics Research Institute and the Institute for Research in Agricultural Engineering of the University The general theme of the Conference will be 'The Business Organization of the Farm" Further information can be obtained from the Conference Secretary, 10 Parks Road, Oxford

The Cambridge University Press will publish early in the New Year "A Short History of the Steam Engine", by Mr H W Dickinson, formerly of the Science Museum, South Kensington The author, it is stated, discusses not only the inventions, but also the inventors.

Biological Effect of Fast Neutrons

CHICK embryo fibroblasts have been irradiated *in vitro* by 2 4 Mev neutrons produced by bombarding heavy wax with ~ 700 microamp of 300 kv deuterium ions This nuclear reaction gives rise to not more than 1 quantum of γ radiation per 200 neutrons [2] and the specimens were completely protected from stray X radiation They were thus exposed to a practically pure beam of fast neutrons The dose given to a culture was estimated from the radioactivity (having the decay period of radio silicon) induced in a tiny pellet of red phosphorus placed directly above it on the cover slip of the culture slide In a separate experiment this radioactivity was correlated with the ionization equivalent of the neutron energy absorbed per unit volume of air as measured by a suitable graphite ionization chamber

The chick fibroblasts were cultivated for five days in Cambridge and then conveyed to Northwood in a portable incubator There the cultures were assessed in terms of their mitotic activity and arranged in comparable batches of six cultures In each experiment the cultures of one batch were exposed one at a time to the neutron beam in a separate laboratory at room temperature and then returned to the incubator (at 37° C) for 80 minutes before being fixed and stained Controls were placed on the bench at room temperature for periods corresponding to the exposure times of the irradiated specimens One batch was placed inside the exposure box but remote from the target as a check on stray X radiation The biological effect was measured by counting all the mitotic cells in the exposed cultures and expressing the result as a percentage of the corresponding control counts The results of the two series of exposures are shown in the accompanying table

Comparable figures for γ radiation have been obtained by Canti and Spear[3] and Spear and Grimmett[4], from which one may calculate values of γ/N the ratio of the γ ray dose (in rontgens) to the neutron dose (in air ionization units) which produces the same biological effect in the same time Calculating this ratio for the *individual slides* using the γ ray data of Canti and Spear and averaging we obtain from Expt 1 (average residual mitosis 81 per cent) $\gamma/N = 22\ 5 \pm 2$ and from Expt 2 (average residual mitosis 54 per cent) $\gamma/N = 11\ 5 \pm 1$, where the probable errors refer to relative values of γ/N According to rough estimates, a ratio of 11 5 corresponds to the production of about the same number of ions per unit volume of tissue by neutrons and by

Probable errors are estimated from the control data

γ rays This large value arises, of course, from the fact that neutron energy, by contrast with γ ray energy, is absorbed to a very much greater extent in material rich in hydrogen than in air

We can find no explanation for the large difference between the two experimental values of γ/N other than that the *shape* of the mitosis dose curve is not the same for neutrons and γ rays This is evident from the figure in which mitosis is plotted against dose for the individual slides The full curve shows Canti and Spear s results for γ radiation at comparable intensity, from which it is seen that if the neutron curve were of the same shape as the γ ray curve none of the doses delivered in Expt 1 should have produced any diminution in mitosis, whereas in fact five out of six slides showed marked reduction in mitosis, the average reduction being 19 ± 6 per cent So far as we are aware, this is the first occasion on which a difference between the mode of action of neutrons and γ rays has been reported

The neutron points appear to define an approximately exponential curve If this is interpreted as implying that mitosis is inhibited by the passage of a single proton through a specially vulnerable region, the diameter of this region can be estimated at about 3 μ Furthermore because the number of ion pairs per unit volume required to reduce mitosis to 50 per cent is approximately the same for neutrons and for γ rays it follows that provided approximately 1 500 ions are produced within this volume, it is immaterial whether the ions are produced along a straight track or at random That is the biological effect is not the result of the direct ionization by the proton or by secondary electrons of a group of molecules which are indispensable for the performance of mitosis

Obviously many more measurements are necessary to establish the exact shape of the neutron mitosis dose curve, but as we cannot continue the experiment for six months owing to the absence of one member (F G S), we wish to direct attention to the important conclusions which would follow if our provisional estimates are substantiated The effect of neutrons on the mitosis of bean root cells is being investigated at the Mount Vernon Hospital, in collaboration with Dr J C Mottram

We gratefully acknowledge the financial assistance of the British Empire Cancer Campaign towards the construction of the neutron generator

Structure of the Crystals of Tomato Bushy Stunt Virus Preparations

WE have examined by X ray methods crystals of the protein material prepared by F C Bawden and N W Pirie[1] from tomato plants suffering from bushy stunt disease The crystals were in the form of isotropic rhombic dodecahedra of average diameter of only 0 01 mm Consequently, no attempt was made to take single crystal photographs Instead, powder photographs were taken of a suspension of the crystals in their mother liquor With a monochromatic beam of copper $K\alpha$ radiation at 40 cm plate distance and long exposure, two lines were observed of spacings 279 A and 160 A respectively The ratio of these spacings is $\sqrt{3}$ 1, corresponding to the (110) and (112) spacings of a body centred cubic lattice of side 394 A This would correspond to a particle diameter of 340 A or a radius of 17 mμ Although the (200) reflection and higher order reflections are not observed the attribution of a body centred cell is probable as it accords with the dodecahedral habit by Fedorov s law

The density of the crystals in solution was determined as 1 286, the wet molecular weight is therefore assuming two particles per cell 24 000 000 On drying and rewetting the crystals can be observed to shrink and swell reversibly The amount of shrinkage measured under the microscope was 80 per cent of the wet dimensions An X ray photograph of a specimen dried over phosphorus pentoxide showed a cell of side 318 A, giving almost exactly the same degree of shrinkage This is we believe the first time that the shrinkage of a crystal on drying has been shown to be the same as the change in the lattice dimensions measured by X rays If the density of 1 35 computed by A S McFarlane and R A Kekwick[2] is assumed to be that of the dry crystals, this would give a molecular weight of 12 800 000 This is considerably higher than the value of 8 800 000 found by them by the centrifuge method The discrepancy may be due to some of the water in the crystal being held zeolitically and lost without further shrinkage To obtain their molecular weight the density of the dry crystals would have to be 1 12 and the wet crystals would contain 63 per cent of water

Transformation of α- and β-forms of 3 6-Anhydro-methyl-Galactosides

THE transformation into α and β forms in equilibrium is the usual result of the digestion with methyl alcoholic hydrogen chloride of either an α or β methylglycoside This change is generally attributed to the initial hydrolysis to the free sugar followed by a mutarotation and the regeneration of the two forms of the methylglycoside

We have recently encountered an example of a substance which does not appear to conform to this interpretation of the isomeric change This substance is 2 4 dimethyl 3 6 anhydro α methyl *d* galactopyranoside, a liquid showing $[\alpha]_D + 73°$ in water and $+99°$ in ether It was prepared by methylation of 3 6 anhydro α methyl *d* galactopyranoside which was obtained by alkaline treatment of 6 tosyl α methylgalactopyranoside The anhydro compound is mentioned also by several other workers[1,2,3] We have found that the liquid dimethyl 3 . 6-anhydro-α-methyl-*d*-galactopyranoside changes, by a brief contact with air containing a trace of hydrogen chloride, to the corresponding crystalline β-form, namely, 2 : 4-dimethyl 3 : 6-anhydro-β-methyl-*d*-galactopyranoside (m p 82°, $[\alpha]_D$ − 77° in water, − 87° in chloroform, − 81° in methyl alcohol) Both forms appear, by ebullioscopic methods, to be monomeric, and this is confirmed for the β-form by X-ray examination.

The same isomeric change from α- to β-form was effected by the addition of a drop of a solution of hydrogen chloride in ethyl alcohol or in ether The velocity of this change is apparent from the fact that with gaseous hydrogen chloride or hydrogen bromide the syrupy α-form appears to pass instantaneously into the crystalline β-form, although the solid mass of the product still contains some of the α-form Inasmuch as there is no loss of methyl from the glycosidic group during these transformations, it is clear that the mechanism does not admit of a stage which passes through the free sugar Moreover, we have prepared the same crystalline substance, namely, 2 . 4-dimethyl 3 : 6-anhydro-β-methyl-*d*-galactopyranoside by following the procedure observed for the α-form, except that we started from β-methylgalactopyranoside It is evident, therefore, that the transformation product derived from the α-form is the true β-form When either the α- or the β-form is treated with methyl-alcoholic hydrogen chloride (2 per cent), at room temperature or at boiling point, polarimetric observations show the rapid establishment of equilibrium of the two forms, and fission, if any, of the 3 · 6-anhydro-ring does not occur to an appreciable extent The presence of the 2 . 4-dimethyl residues seems to stabilize the 3 : 6-anhydro-ring in the presence of acid reagents. The corresponding glucose derivative, 3 : 6-anhydromethylglucopyranoside, does not display with acid reagents instability of the anhydro-ring

Detailed examination of 3 6-anhydro-ring forms has recently assumed a new importance inasmuch as an enantiomorph in the *l*-galactose series has been isolated from a study of the hydrolytic products of agar-agar[3] [4]. Recognition of 2 . 4-dimethyl sugars in the form of their methylglycosides has become a live problem for the reason that we have required these sugars in order to identify the components having 1 : 3- and 1 . 6-glycosidic links which, in the course of our work during the past five years, have been found to occur in the polysaccharide derived from gum arabic Both the α- and β-forms of 2 4-dimethyl 3 : 6-anhydro-methyl-*d*-galactopyranoside are rapidly hydrolysed by dilute acids From the β-form, 2 · 4-dimethyl 3 . 6-anhydro-galactose, m p 112°, was isolated, and this gives the anilide, m p. 123°, and also, by oxidation, the corresponding 2 · 4-dimethyl 3 . 6-anhydro-galactonic acid and its amide, m.p 151°.

3 : 6-Anhydro-*l*-galactose in Agar

IN continuation of our former communication[1] we are now able to confirm that the substance (*X*) derived from agar is a derivative of 3 : 6-anhydro-*l*-galactose as recently advanced by Hands and Peat[2]. 3 : 6-Anhydro-β-methyl-*d*-galactoside, m p. 118°, $[\alpha]_D^{20°} = -113°$ in water has now been synthesized from the crystalline triacetyl 6-*p*-toluenesulphonyl α-*d*-galactosyl-1-bromide ($[\alpha]_D = +157°$) of Ohle and Thiel[3] by treatment with silver carbonate and methyl alcohol followed by deacylation with sodium hydroxide Methylation of this substance yielded quantitatively crystalline 2 . 4-dimethyl 3 . 6-anhydro-β-methyl-*d*-galactoside, m p 82°, $[\alpha]_D^{20°} = -77°$ in water, − 86° in chloroform, which is undoubtedly the enantiomorph of (*X*), since the properties are the same but the sign of the rotation is reversed (mixed m p 65°) We have obtained further confirmation of this point by the preparation of the anilides of the dimethyl anhydro sugars, 2 : 4-dimethyl 3 : 6-anhydro-*d*-galactose anilide having m p 118°, whilst the corresponding derivative from agar had m.p 117° strongly depressed on admixture with the *d*-anilide Furthermore, the properties and stability of the lactones produced on oxidation are in agreement with these findings, so that the substance (*X*) must be regarded as 2 : 4-dimethyl 3 : 6-anhydro-β-methyl-*l*-galactoside

The preparation of 2 : 4-dimethyl 3 : 6-anhydro-α-methyl-*d*-galactoside was described in our former letter[1] and isolated as an oil, $[\alpha]_D = +87°$ in chloroform, and both this oil and the crystalline substance synthesized above reach the same equilibrium ($[\alpha]_D^{18°} = +22°$) in cold *N*-sulphuric acid. It has also been found that this oily 2 : 4-dimethyl 3 : 6-anhydro-α-methyl-*d*-galactoside is very sensitive to traces of acid ; contact with cold methyl-alcoholic hydrogen chloride causes a remarkably rapid fall in optical rotation and the crystalline β-form can then be readily isolated.

"Methyl Epiglucosamine" and 2-Amino α-Methylaltroside

DURING recent years, a series of papers from this laboratory have shown that derivatives of glucose may be converted smoothly into derivatives of altrose, galactose and gulose by means of optical inversion within the molecule[1]. In each case the key substance to such a conversion has been an anhydro-compound of the ethylene oxide type in which the ring is broken under the influence of alkali. For example, 2 : 3-anhydro 4 : 6-benzylidene α-methylalloside or 2 : 3-anhydro 4 : 6-benzylidene α-methylmannoside, in our experience, invariably yield derivatives of altrose when treated with alcoholic caustic potash or sodium methoxide solution.

We are now able to report that an analogous series of reactions may be carried out with derivatives of galactose, and that various crystalline derivatives of idose have thus been obtained (Robertson and Tetlow, unpublished result).

As a natural consequence of this work, we extended our researches to the action of ammonia on 2 3 anhydro 4 6 benzylidene α methylmannoside and 2 3-anhydro 4 6 benzylidene α methylalloside The former, on treatment with ammonia gives a quantitative yield of 3 *amino* 4 6 *benzylidene* α *methyl altroside*, m p 188°, $[\alpha]_D$ + 88 9° in chloroform (c = 0 517) When the benzylidene residue is removed from the above substance by means of 1 per cent hydrochloric acid, 3 *amino* α *methylaltroside hydrochloride* is obtained in 76 per cent yield The substance has m p 209° with decomposition $[\alpha]_D$ − 149° in water (c = 1 028) and is identical with the methyl epiglucosamine hydrochloride prepared by Fischer, Bergmann and Schotte[2] who record m p 210–211° with decomposition, and $[\alpha]_D$ − 147° in water Fischer s methyl epiglucosamine has since been proved to be 3 amino α methylaltroside by Freudenberg, Burkhart and Braun[3]

In analogous fashion, 2 3 anhydro 4 6 benzylidene α methylalloside gives a quantitative yield of 2 *amino* 4 6 *benzylidene* α *methylaltroside* m p 168 $[\alpha]_D$ + 104 7 in chloroform (c 1 346) The above was in turn converted into 2 *amino* α *methylaltroside* m p 193°, $[\alpha]_D$ + 107° in chloroform (c 1 109) in 70 per cent yield The position assigned to the amino group in the above case has not yet been definitely proved, but from analogy with the action of alcoholic caustic potash and sodium methoxide solution on 2 3 anhydro 4 6 benzylidene α methylalloside there can be little doubt that the amino group is in position 2

Full details of the above transformations will be published shortly

A New Synthesis of Aromatic Arsenic Compounds

IN the course of a systematic study of reactions between aryl diazonium chlorides and chemical elements, it has been found that aromatic arsenic compounds may be prepared by warming a diazonium chloride under acetone with arsenic powder and chalk With benzene diazonium chloride there is obtained a water soluble product from which tri phenylarsine sulphide has been obtained by precipitation with hydrogen sulphide

The reaction with arsenic is therefore analogous to that with antimony[1], which yielded triarylstibine dichlorides and other aromatic antimonials However, when antimony powder is used, the reaction sets in at 0°, but with arsenic powder there is no reaction in the cold There is a similar difference in degree of reactivity with the elements tellurium and selenium[2], which follow antimony and arsenic in the Periodic Table

The reaction with bismuth powder has also been investigated, but, although the bismuth is attacked when the mixture is heated, aromatic bismuthines do not seem to be formed They may, however, be unstable under the conditions of the reaction

Attention has already been directed to the theoretical significance of these reactions[3], and of the reactions with metals such as mercury and silver which may be attacked by free chlorine atoms but would not be affected if the decomposition of the aryl diazonium chloride took either a molecular or an ionic course A still more striking example of the reactivity of the chlorine has now been found gold powder is also attacked by benzene diazonium chloride under acetone kept neutral with chalk and auric chloride is formed in considerable quantities

In contrast it is rather curious that thallium metal seems to be inert for aromatic thallium compounds can easily be prepared

The scope of this new synthesis of aromatic arsenicals is under investigation in these laboratories

Alimentary Exudative Diathesis

DURING the work on K avitaminosis in chicks it is often observed that in some animals large amounts of transparent fluid accumulate for example, in the subcutaneous connective tissue It has now been possible to produce this symptom systematically by using a diet from which the protein has been very thoroughly extracted by alcohol

The accumulations of fluid may be found in all parts of the body but most frequently on the breast and abdomen They are located in the subcutaneous connective tissue or under the skin and in some cases under the fasciæ of muscles Intra peritoneal accumulation is rare

The fluid has the same composition as blood plasma and it often clots when being removed by a pipette In some cases the coagulation has already taken place *in vivo*

Simultaneously with the accumulation of fluid hyperæmia slight hæmorrhage and accumulation of leucocytes occur in connective tissue chiefly in fat tissue under the skin in mesenteric fat or in fat tissue on the serosa of the gizzard A similar condition may also but less frequently be seen in muscle tissue Other tissue has not been observed to be affected The changes resemble a sterile inflammation It has not been possible to propagate any micro organism from the inflamed tissue or from the fluid

The fluid is supposed to originate by exudation from such inflamed tissue in which the capillary wall is rendered abnormally permeable The degree of permeability is such that the plasma may escape while the erythrocytes are only passing through to a limited extent

When chicks weighing 100–130 gm are fed the basal diet, 50–80 per cent of them will show the symptom after 6–30 days The exudates often disappear in about a week, even if the food is not changed, and some of the animals get several attacks during the experiment

Addition of hesperidin together with ascorbic acid to the diet does not prevent the symptom, and it is therefore not likely that the disease is due to deficiency in Szent Györgyi's vitamin P

Neither is it likely that the disease is due to lack of vitamin K, because it has been observed in chicks receiving 0 1 per cent of petrol ether extract of alfalfa in addition to the basal diet. Such a diet contains 20–30 units of vitamin K per gm, an amount which secures normal blood clotting and prevents the 'ordinary' hæmorrhage of K-avitaminosis 40 per cent of dried yeast in the diet gives no protection.

The resemblance of the symptom to an allergic reaction might suggest that the protein had been rendered toxic by the extraction process, for example, by being altered in such a way that a trace is absorbed without being broken down by the digestive enzymes

However, certain observations make it probable that the exudative diathesis is a deficiency disease. Thus the addition of 5 per cent dried alfalfa or 0·5 per cent petrol ether extract or alcohol extract of alfalfa afforded a very material reduction of the percentage of the animals showing the symptom, while 1 5 per cent aqueous alfalfa extract or 0 5 per cent alfalfa ash gave no protection

These and other observations suggest that the disease is prevented by a specific petrol ether- and alcohol-soluble factor occurring in dried alfalfa, but that this material is no powerful source It is therefore proposed to attempt to find a richer source of the protective factor and to concentrate and differentiate it in the usual way

Trimethylamine Formation in Relation to the Viable Bacterial Population of Spoiling Fish Muscle

Suwa[1] and Poller and Linneweh[2] found that the trimethylamine oxide occurring in the muscle of certain sea fishes is reduced to the corresponding volatile amine during its spoilage by bacteria Recently, Beatty[3] has shown that it is fairly certain that at least 94 per cent of the trimethylamine found in decomposing cod fish muscle arises from the trimethylamine oxide present in this tissue, and not from the other possible precursors Sterile fish muscle[4] and muscle press juice[5] do not reduce the oxide

These, and similar observations made by other investigators, have led to the suggestion that the simple determination of the amount of trimethylamine in sea fish muscle might prove a convenient and accurate chemical test by which its stage of decomposition could be accurately judged[5,6,7], and attempts have been made to compare the viable bacterial counts (or the logarithms of these counts) with the amount of trimethylamine in cod fish muscle press juice[5] or in spoiling haddock muscle[7]

Recent work at this station[8] has shown that, while there is undoubtedly an increase in trimethylamine as the viable bacterial population of lightly smoked sea fish fillets increases, there is by no means a constant relationship between these two values. It seemed possible that not all bacteria occurring in spoiling fish muscle are capable of reducing trimethylamine oxide, and that the discrepancy noted above might well be due to an unequal distribution of the reducing and non-reducing organisms in different samples of fish

In order to investigate this possibility, thirty micro-organisms (15 micrococci, 4 flavobacteria, 6 achromobacteria and 5 yeasts) were isolated at random from fresh halibut and red cod muscle, and from smoked fillets of halibut, red cod and grey cod. Only three of these organisms (2 species of micrococci and 1 achromobacter) formed trimethylamine when grown in dilute aqueous halibut muscle extract sterilized by filtration, or when washed suspensions of their cells were incubated anærobically in Thunberg tubes in the presence of halibut muscle juice, with or without added trimethylamine oxide, at pH 7·0 for 16 hours at 25° C. Under the last-named conditions, the reduction of the oxide by the three cultures capable of effecting its reduction was found to be linear and practically quantitative, suggesting the presence of a specific dehydrogenase enzyme (or enzymes) catalysing the reaction By inoculation of aseptically excised cod fish muscle with trimethylamine-forming and non-trimethylamine-forming species of *Micrococcus*, samples of fish with either high or negligible quantities of trimethylamine, but with high bacterial counts in both instances, have been obtained

From these results, it would seem unlikely that the trimethylamine content alone will prove to be a satisfactory criterion of the degree of bacterial contamination of sea fish muscle, unless the population of trimethylamine-forming to non-trimethylamine-forming bacteria proves to be fairly constant in all cases As yet the full mechanism of the bacterial reduction of trimethylamine oxide to trimethylamine remains to be determined, though recent work by Watson[9] suggests that the lactic or pyruvic dehydrogenase systems are capable of catalysing this reaction

A Correlation between the Chemical Constituents and Morphological Structure of certain *Thesium* Species

A CHEMICAL examination of *Thesium virgatum* has been carried out, and two characteristic constituents of the plant tissues have been isolated—a phlobatannin, and an amorphous substance which yields glucose and a steam-volatile oil on hydrolysis These constituents are readily detected in the plant material by a test tube reaction, the phlobatannin with mineral acids yielding a red phlobaphene, and the glycosidic material the free essential oil.

Three of the four sections of the *Thesium* genus mentioned in the "Flora Capensis" are represented in the Cape Peninsula In general, these sections are well defined; but the boundaries between them are not absolute. In an attempt to follow the gradation from group to group chemically, the above qualitative test has been applied to the vegetative portions of a number of *Thesium* species. Arranging the species roughly in the order of evolutionary development as given in the Flora Capensis , the following results were obtained

Section I Imberbia, comprising the species *crassifolium corymbuligerium, ericæfolium, nigromontanum commutatum, virgatum, strictum* All those contained the essential oil glycoside and the phlobatannin Section II Barbata, comprising the species *paniculatum euphrasioides, cuspidatum, acuminatum scabrum pubescens, capitatum* Only *paniculatum* contained the essential oil glycoside, but all except *scabrum, pubescens* and *capitatum* contained phlobatannin Section IV Annulata comprising the species *funale aggregatum, spicatum*, none of which contained either substance.

Although complete seasonal variations have not yet been studied, there seems to be a definite correlation between the structure of the *Thesium* flower and the chemical constituents of the plant In Section I, we have the open type of flower, and with progression to the closed type there is gradual disappearance of the essential oil glycoside and phlobatannin through intermediate types such as *T cuspidatum* and *T euphrasioides* which contain phlobatannin alone

A more detailed account of an examination of the essential oil derived from the glycosidic extract from *T virgatum* will be published elsewhere

Double Ovaries in Some Chinese Birds of Prey

IT is generally believed that, in the normal condition, there persists only a single gonad the left ovary in female birds But bilateral ovaries are not uncommon in hawks and some species of other birds The finding of such paired ovaries in European and American birds, and even in African birds has already been recorded So far as I know however very little has been recorded on the bilateral development of ovaries in Oriental birds The following is a list of birds of prey which were collected in the Western Hills, near Peiping (Peking) China and examined by me in October last It may be of interest to students of embryology and comparative anatomy as well as to those who are engaged in the study of birds

Name of Species	No of females examined	No of ovaries
Circus cyaneus cyaneus (Linn)	13	2
Accipiter nisus nisosimilis (Tickell)	2	2
Buteo hemilasius (Temminck and Schlegel)	2	1
Buteo burmanicus burmanicus Hume	2	1
Aquila clanga fulvescens Gray	1	2
Milvus lineatus lineatus (Gray)	1	1
Cerchneis tinnunculus japonicus (Tichurst)	–	1

Of the seven species examined, three species only possess two ovaries, and the remaining four species have only a single ovary

There was no exception in species with paired gonads. Of the thirteen specimens of hen harrier (*Circus cyaneus cyaneus*) examined, all had two ovaries This is also true in the case of the Asiatic sparrow hawk (*Accipiter nisus nisosimilis*) and great spotted eagle (*Aquila clanga fulvescens*)

The materials thus studied were secured during the autumn migration, so that the gonads are not well developed All the eggs are more or less uniform in size, and generally speaking, they are rather small

Effect of Collisions on the Intensities of Nebular Lines

MENZEL[1] has recently stated that There appears to be a widespread misconception concerning the effect of electron collisions on the intensities of forbidden lines In the conventional treatment to which the above statement objects the intensity is given by the formula

$$I = \frac{MA_{21}h\nu}{A_{21}+b_{21}} = \frac{Mh\nu}{1+b_{21}/A_{21}} \qquad (1)$$

where M is the number of atoms excited to the upper state per unit of time A_{21} is the probability of spontaneous emission and b_{21} is the probability of removal from the upper state by collision with electrons atoms molecules etc b_{21} in general increases with the density of these particles and is proportional to the density if the composition and velocity distribution are not altered In this case I remains approximately at the value $Mh\nu$ as long as the density is so low that $b_{21} < A_{21}$ When $b_{21} \gg A_{21}$ however $I = MA_{21}h\nu/b_{21}$ that is I falls off inversely as the density if M the rate of excitation of atoms excited to the upper state, is held constant

Menzel considers there is a fallacy in holding the rate of excitation M constant and proposes the use of the formula for I

$$I = N_1\frac{\omega_2}{\omega_1}e^{-h\nu/kT}\left(\frac{1}{1+A_{21}/b_{21}}\right)A_{21}h\nu \qquad (2)$$

By the use of this formula, Menzel postulates that the rate of excitation M of atoms to the upper state is proportional to the electron density With this assumption the intensity increases with the density at densities that are so low that $b_{21} \lesssim A_{21}$ and asymptotically approaches a constant value at higher densities where $b_{21} \gg A_{21}$ Thus as Menzel states I reaches a maximum when the electron density is high

Formula (2) gives the intensity for the case in which both the excitation and de excitation of N_1 atoms is caused by impacts with an electron gas having a Maxwellian velocity distribution corresponding to a temperature T The formula is not sufficient to discuss the conditions under which thermodynamical equilibrium is reached, since the effects of absorption and induced emission are neglected If they are included, it can easily be seen that, for any finite value of the electron density and the transition probability, the bracketed factor in (2) becomes unity only when the radiation density has the value prescribed by Planck s law for the temperature T Only the Boltzmann factor appears then in (2) This, of course, is merely an example of the well known fact that in complete thermodynamic equilibrium the density of radiation at any wave length is a function of temperature alone and is independent of the probability of spontaneous emission of any line that happens to fall at the wave length, and of the electron density The formula does not apply to any laboratory case since it neglects the effect of de-excitation by atoms, molecules, walls of discharge tubes, etc., which play a major part in laboratory sources. Even in astronomical sources its applicability is very limited, since it requires that the energy available for excitation must increase in a prescribed way as the density is increased

Comparing the density of radiation given by the mechanism postulated by (2) with that of complete thermodynamic equilibrium, it is evident that at low electron densities the permitted (A_{21} large) and forbidden (A_{21} small) lines depart equally from the equilibrium case. At high electron densities, however, de-excitation by collision causes the forbidden lines to depart much farther from the equilibrium case than the permitted lines.

Which of these treatments, M constant or M proportional to density, one uses is largely a matter of personal preference, since neither can lay claim to any uniqueness in describing either astronomical or laboratory phenomena Indeed equally strong claims can be made for considering the intensity coming from unit volume, in which case the number of atoms capable of being excited (N_1 in 2) also increases with the density M then becomes roughly proportional to the square of the density, and an even greater increase of I with the density is obtained than that given by (2)

The important facts which hold true in all of these cases are:

(1) At low densities where de-excitation by collision is negligible, the number of quanta emitted is practically equal to the number of atoms excited regardless of whether the lines are permitted or forbidden Because of the lower excitation potential of the forbidden lines, they become under these conditions the true resonance lines of the atoms or ions concerned. The forbidden lines therefore take a very major role since a large part of the available energy is transferred to them

(2) At high densities the excitation of the forbidden lines remains large. Because, however, of the very high probability of de-excitation by collision compared to the probability of spontaneous emission, only a negligible fraction of the atoms excited succeeds in emitting forbidden lines. Under these conditions, therefore, practically all of the available energy appears in the permitted lines.

Photochemistry of Ammonia

THE mechanism of the photochemical decomposition of ammonia has been the subject of considerable discussion lately[1], from which it would appear that the nature of the reaction is almost completely elucidated. The experiments to be mentioned below were designed to settle the few remaining uncertain points regarding the reaction. In point of fact, however, they have opened the results to a new interpretation.

The relevant experimental evidence, discussed in the references cited above, may be summarized thus. From the diffuse nature of the absorption spectrum and the absence of fluorescence, it was concluded that each molecule on absorbing a quantum dissociated into NH_2 and H. The low quantum yield—for example, 0·3 at 20° C. and 100 mm. pressure—was interpreted as due to a back reaction, which was supported by the fact that atomic hydrogen inhibited the reaction Using para hydrogen to measure the stationary concentration of atomic hydrogen, it was found that this concentration was much smaller than that calculated on the assumption that H atoms disappear by the reactions $H + H + X \rightarrow H_2 + X$ and $H + NH_2 + X \rightarrow NH_3 + X$, where X is a third body This anomaly was explained by assuming that NH_2 radicals combine to form hydrazine, which in turn rapidly reacts with atomic hydrogen, thereby maintaining a low stationary atom concentration.

In order to compute the magnitude of this latter process, the effect has been measured of hydrazine on the stationary atomic hydrogen concentration (estimated by para hydrogen conversion) produced by photo-excited mercury atoms The results showed that the low concentration is not due to hydrazine, for the pressure of hydrazine required to account for the low concentration of hydrogen atoms could not possibly be formed during the course of a normal ammonia experiment

This point was made doubly sure in the following way If hydrazine is responsible for the low concentration, then ammonia *undergoing photo-dissociation* should also inhibit the para hydrogen conversion photo-sensitized by mercury atoms A mixture of ammonia and para hydrogen was therefore exposed first to a mercury resonance lamp and then simultaneously to the lamp and to a zinc spark which dissociated the ammonia There was no appreciable inhibition of para conversion when the ammonia was being dissociated, even though conditions were such that inhibition of ammonia decomposition by atomic hydrogen could be detected

The conclusions to be drawn from these experiments are that the low hydrogen atom concentration is not due to the presence of hydrazine, which substance plays no significant part in the photo-chemistry of ammonia, except under special conditions, and that the secondary reactions only involve $H + H \rightarrow H_2$, $NH_2 + NH_2 \rightarrow 2H_2 + N_2$ and $H + NH_2 \rightarrow NH_3$

Another series of experiments gave the probable clue to the dilemma Using the same intensity of radiation for exciting mercury atoms and for dissociating ammonia, it was observed that the ratio of the rates of para hydrogen conversion is very nearly equal to that expected if only one quarter of the ammonia molecules absorbing light yield the products NH_2 and H

These experiments therefore suggest that only a fraction (given approximately by the quantum yield) of the ammonia molecules undergo primary dissociation to H and NH_2, which react in the fashion mentioned above. The remainder lose their energy by chemically ineffective processes.

Fluorescence of Solids

THE following observations may be of interest in view of the present interest in problems of fluorescence of solids Anthracene (I) in the solid state fluoresces blue with a high efficiency, the absorption band lying at wave lengths shorter than 3800 A Solid naphthacene (II) is yellow in colour and fluoresces very faintly, and solid pentacene (III) is dark bluish and does not fluoresce appreciably In dilute solid solution in anthracene, however, the latter hydrocarbons fluoresce vividly, the former greenish yellow and the latter red

I

II

III

The chief point of interest is that this fluorescence is stimulated by light absorbed by the anthracene, while the blue anthracene fluorescence is almost entirely suppressed These phenomena closely resemble those observed with a typical inorganic fluorescent solid such as zinc sulphide, the emission of which is completely changed by minute additions of copper, etc

It seems one must suppose, that an electron free to move is liberated by absorption of light within the anthracene crystal, and that the positively charged anthracene molecule quickly regains an electron (without emission) by an exchange through the crystal from a distant naphthacene or pentacene molecule The latter molecule, now minus an electron emits its characteristic fluorescence when a free electron returns to it Since the crystal structure of anthracene is well understood it is possible that these phenomena are capable of theoretical treatment

Points from Foregoing Letters

Dr F G Spear Dr L H Gray and Dr J Read report that the relation between the dose and the percentage residual mitosis in *in vitro* cultures of chick embryo fibroblasts after irradiation with D D neutrons is not the same as the sigmoid relation found for γ radiation but is more nearly exponential An exponential relation would be anticipated in the case of neutron irradiation if inhibition of mitosis resulted from the production of about 1 500 ion pairs in a volume of about 3 μ in diameter

X ray study of crystals obtained from tomato bushy stunt virus preparations indicate according to Prof J D Bernal I Fankuchen and D P Riley a particle size of 340 A diameter and a molecular weight of 24 million, for the wet particle of density 1 286 If the density of 1 35 computed by McFarlane and Kekwick is assumed to be that of the dry crystals, it would give for these a molecular weight of 12 8 million, a substantially larger figure than the value of 8 8 millions derived from experiments with the ultracentrifuge

The almost instantaneous change of the syrupy alpha form into the crystalline beta form of the 2 4 dimethyl 3 6 anhydro methyl *d* galactopyranoside in presence of traces of gaseous hydrochloric acid indicates according to Prof W N Haworth J Jackson and Dr F Smith, that the usual mechanism assumed for such transformation namely initial hydrolysis to the free sugar followed by a mutarotation and the regeneration of the two forms of the methylglycoside, does not apply in this case

Dr E G V Percival and I A Forbes confirm that the substance recently isolated from agar is a derivative of 3 6 anhydro *l* galactose They have synthesized its enantiomorph 2 4 dimethyl 3 6 anhydro β methyl-*d* galactoside, which has the same properties but opposite optical rotation

Various crystalline derivatives of idose have been prepared from galactose derivatives by Dr G J Robertson, W H Myers and W E Tetlow by employing an anhydro compound of the ethylene oxide type in which the ring is broken under the influence of alkali They have further prepared 2 amino α methyl altroside and 3 amino α methylaltroside hydrochloride the latter identical with methyl epiglucosamine hydrochloride

Dr W A Waters reports that aromatic arsenic compounds are formed when arsenic powder is warmed with an aryl diazonium chloride under acetone containing chalk Under the same conditions gold is also attacked and yields auric chloride but thallium seems to be inert

Chicken fed upon a diet in which the protein has been very thoroughly extracted by alcohol may develop in the connective tissues large accumulations of transparent fluid of the same composition as the blood plasma Dr H Dam and J Glavind consider that this is the effect of a deficiency disease

It is stated by Dr H L A Tarr that only certain and probably a small proportion of the micro organisms which are commonly associated with decomposing sea fish muscle are able to reduce the trimethylamine oxide occurring therein to trimethylamine This fact probably accounts for the finding that there does not always appear to be a close correlation between the viable bacteria count and amount of trimethylamine in this medium

P C de Kock and Prof W S Rapson find that in various species of the South African genus *Thesium* the presence or absence of the easily identifiable chemical constituents phlobatannin and/or glycosidic material, corresponds to the grouping of those species according to the structure of their flowers and other morphological characters

Prof I S Bowen and Dr R Minkowski suggest that Menzel s recent discussion of the effect of collisions on the intensities of nebular lines is based on a special case, in which the apparent increase in intensity of forbidden lines with density is a result of the assumption that the rate of excitation increases with the density They emphasize that, while forbidden lines take a major role at low densities, de excitation by collisions prevents them from emitting an appreciable fraction of the available energy at high densities

Research Items

Jades from Central America

A NUMBER of the jades bequeathed to the British Museum by the late Mr T W Gann are figured and described by Mr T A Joyce in the *British Museum Quarterly* 12 4 1938 This collection of Central American carvings in jadeite and basalt is said to be one of the finest ever acquired over a number of years by a single individual The sites from which they were obtained are unfortunately not defined with accuracy but they obviously come from the Central Maya area and in the main from British Honduras They illustrate the extraordinary facility with which the early inhabitants of Central America ignorant of the use of iron could carve hard stone The finest piece a jadeite plaque represents a seated chief in full regalia with an attendant in the style which is associated with Copan and recalls the seated figures represented on a lintel from that site now in the British Museum It is clear that the plaque has been trimmed possibly owing to an accidental breakage in early times Ornaments of this class were regarded as heirlooms and much treasured by later generations owing to the fact that jadeite seems to have become exceedingly rare A basalt mask exhibiting a high degree of skill in modelling was evidently inlaid with other materials to represent eyes and teeth but as in most other examples the inlay has disappeared Incised lines on cheeks and chin probably represent designs painted on the face Some of the pendants representing a human head enclosed in the jaws of a monster are symbolical of the earth which swallows the sun every evening There are no glyphs to give a clue to the dating of the pieces but evidently they antedate considerably the discovery of America An eccentric flint from the collection is described as the most remarkable example of stone flaking technique which has yet come from Central America

Studies in Alcohol

W W JETTEN (*Amer J Med Sci* 196 475 487 1938) carried out two series of observations The first which was concerned with the diagnosis of acute alcoholic intoxication by a correlation of clinical and chemical findings was made on 1 159 consecutive persons admitted to hospital with a diagnosis of acute alcoholism In 1,150 cases blood was obtained for analysis and in 381 the urine was also examined The results were as follows Alcohol was found in the blood of 1 000 cases and in all the 381 cases in which the urine was examined Of the 1 000 cases with alcohol in the blood 779 (77 9 per cent) were found in the concentration groups of 0 15 to 0 30 per cent alcohol inclusive and of the 381 cases in which the urine was examined 266 (70 per cent) showed a concentration of 0 20 to 0 35 per cent alcohol inclusive Clinical intoxication was found in the blood series in approximately 10 per cent of the cases with a concentration of 0 05 per cent alcohol in 18 per cent at 0 10 per cent alcohol, in 47 per cent at 0 15 per cent alcohol , in 83 per cent at 0 20 per cent alcohol , in 90 per cent at 0 25 per cent alcohol , in 95 per cent at 0 30 per cent alcohol and in 100 per cent in a concentration group of 0 45 per cent alcohol The second group of observations consisted in the determination of the alcohol content of the blood at regular intervals following ingestion of 1, 1 25 1 5 and 2 c c of alcohol per kgm of body weight in twenty non alcoholic individuals that is occasional drinkers or total abstainers Jetten found that acute clinical intoxication occurred in 50 per cent of the cases in which the alcohol concentration in the blood ranged from 0 075 to 0 125 per cent in 57 per cent in concentrations from 0 125 to 0 175 per cent and in 100 per cent in concentrations from 0 175 to 0 225 per cent alcohol The incidence of acute clinical intoxication in these non alcoholic individuals at low alcoholic concentrations was much higher than the incidence at similar concentrations in a larger group of chronic alcoholics

Conjugal Tuberculosis

H COUETOUX (*Thèse de Paris* No 387 1938) has made a study at two dispensaries in Nantes of 816 married couples of whom one at least was tuberculous and found that in 112 (13 72 per cent) the other partner was also affected In the adult population of Nantes calculation of probabilities showed that if there were no question of contagion between husband and wife the rate of tuberculous infection among couples would be 1 69 per cent Comparison of these two figures shows that the first member of the married couple to contract tuberculosis is responsible for infection of the second in 12 03 per cent of the couples in which tuberculosis is present Conjugal contagion therefore is the most important factor in the causation of tuberculosis in the second member of a married couple

Eggs of the Komodo Lizard

IN the Sourabaya Botanical and Zoological Gardens in the Dutch East Indies are four specimens of the giant lizard *Varanus komodœnsis* two of which have been there since 1927 and two since 1935 In July 4 1937 individuals were seen in copulation and by August 13 it was discovered that the female which had been placed in an enclosure with abundance of humus had laid two eggs which turned out to be addled (*Treubia* 16 365 August 1938) Later, a nest of eggs was found in the heap of humus , one egg was extracted and found to weigh 136 grams but the others did not hatch and when the nest was opened in January 1938, only 14 desiccated parchment like egg shells were revealed This excavation however revealed a second nest with 10 eggs One of these was examined at the time and contained a living embryo which had not become immersed in the mass of light yellow yolk The remainder left to develop were found five weeks later to be shrivelled but six contained embryos in various stages of development the largest measuring 27 cm from snout to tip of tail The authors E L Tänzer and Jhr W C van Heurn, consider that the embryos died at an early stage of development, and that the cause of death was some deficiency in the humus environment It is to be hoped that future results will be more successful, for the development of a skull so curious as that of the Komodo lizard is a matter of great interest

Brackish-water Fauna of Orkney

THE lochs of Stenness and Harray present an interesting biological problem, for while they are connected with each other and, by way of Stenness, open into the sea, they present very different aspects of brackish water conditions. Both receive fresh water streams, but the former is partly tidal and its fauna and flora have a predominantly brackish character throughout an area which at the time of examination by Dr. Edith A. T. Nicol showed salinities varying from 9 to 26·8 parts per thousand (*Proc. Roy. Soc. Edinburgh*, 58, 181; 1938). On the other hand the Loch of Harray receives a contribution of sea water only at spring tides, and as a consequence is almost fresh (salinity 0·6–4·3 parts per thousand) and possesses a fauna and flora almost wholly composed of freshwater species. The two lochs are the only Scottish localities for the mollusc *Neritina fluviatiles*, and the dwarfing effect of brackish conditions is seen in the miniature size of this species and of *Mya arenaria*. *Hydrobia jenkinsi*, present in both lochs, appears to be a recent immigrant.

Sheep Population of South Australia

THE number of sheep present in South Australia has been recorded yearly since the foundation of the Province in 1836. Dr. J. Davidson has analysed these records and compared the data with the Verhulst-Pearl logistic curve expressing the course of the growth of a natural population (*Trans. Roy. Soc. S. Australia*, 62, 141; 1938). The progress of sheep numbers during the past hundred years, while showing for the first forty years a rapid and steady increase which coincided with the theoretical growth of a population, began to exhibit marked fluctuations from the normal curve so soon as the limit of density was approached. Saturation density of the sheep population which a natural pasture can carry is determined in the main by the feeding value of the pasture and the regrowth of plants eaten by the sheep. When the density exceeds this value the balance is upset and the carrying capacity of the area will decline. Recovery of numbers depends upon the degree of overgrazing and the power of the pasture to recover. In the arid climate of South Australia recovery is mainly dependent upon rainfall, and may be considerably delayed.

Role of Fructosans in Carbohydrate Metabolism

IN a recent study of the interrelationship of sucrose, glucose and fructose (including fructosans) in the barley plant (Archbold, H. K., *Ann. Bot.*, N.S., 2, 183, 403; 1938), attention is once more focused on the question of interconversion of these sugars in stems and leaves. The methods of sugar determination are reviewed in the first paper, and the results presented in the second. The observation that, while the concentration of reducing sugars decreases from apex to base in the stem, that of fructosan and of sucrose rises, entirely supports the view that fructosans are secondary in origin, in spite of the fact that they are here found in leaves; and that they arise from reducing sugars and not from sucrose. Any condition which limits the demand for soluble sugars (for example, removal of ears, nitrogen deficiency, etc.) causes an increased accumulation of fructosan in the leaves, where under normal conditions it is present only in small amounts. It is shown that in leaves no conversion of fructose to glucose is necessary to account for polysaccharide production, provided that fructose is the sole source of carbon for respiration, and largely for protein synthesis. In stems, however, such a conversion does seem necessary. On the other hand, the formation of fructose from temporarily immobilized sugar seems to necessitate conversion of glucose to fructose, a process which may be reversed when sugars are again in demand.

Morphology of *Sorghum* Species

A STUDY of the internode and sheath lengths of *Sorghum* species by Rangaswami Ayyangar and his co-workers has shown that, in general, the longer the species is in reaching maturity, the taller the plants and the greater the number of internodes (*Proc. Ind. Acad. Sci.*, 7, 1938). On the basis of these measurements, they divide the *Sorghum* species into three groups; in group 1, including the early species, the internode length shows a steady increase from the base of the plant to the peduncle; in group 2, the medium species as regards maturity, the internode length increases up to a peak, then falls before increasing again to the peduncle; whilst in group 3, the late species, the internode length rises to two peaks before finally rising to the peduncle. Thus groups 2 and 3 show a unimodal and bimodal distribution of internode lengths respectively. The internodes are apparently measured from ground level; for greater exactitude, it would have been useful to indicate the position of the first internode measured relative to the internodes produced by the shoot above the coleoptile. The sheath lengths give the same general distribution as internode lengths, but to a less marked extent. The tillers do not necessarily show the same internode distribution as the main axis; in some bimodal species, the tillers, with their shorter growing period, have a unimodal distribution. In breeding, short stems, early maturity, coupled with unimodal distribution, behave as simple dominants to tall stems, late maturity and a bimodal distribution of internode lengths.

Mould Fungi of the Punjab

H. CHAUDHURI has recently published a detailed annotated list of moulds of the Punjab (*Proc. Ind. Acad. Sci.*, Sect. B, 8, No. 2, Aug. 1938). Sixteen species of the genus *Penicillium* are described, and with the collaboration of M. Umar, 31 species of *Aspergillus* are further considered. Cultural and microscopical characters are given in detail for many of the important species, whilst references to further work are cited for all. The mould flora of the Punjab contains some indigenous elements, but many of the species described are widely distributed. Species of *Aspergillus* and *Penicillium* which occur in India, but have not so far been recorded in the Punjab, are included in the papers, thus making them, in effect, part of a mould flora of India.

Plant Diseases of Greece

THE *Verticillium* wilt of cotton is distributed over wide regions where the host can grow, but the advent of this disease to Greece is somewhat puzzling. J. A. Sarejanni discusses the question in a paper entitled "La Verticilliose du Coton en Grece" (*Ann. Inst. Phytopathologique*, Benaki, 2nd year, 2nd fascicule, 79–85; 1936). Native Greek cotton is immune to attack by the fungus *Verticillium alboatrum*, but several American varieties were introduced a few years ago. These were quickly attacked by the wilt fungus, and after a survey of possible sources of infection, it is concluded that spores of the organism were either carried upon the fibres surrounding the seed, or were present in the water of irrigation. The latter method, though implying wind transmission of spores over considerable distances, appears to be the more likely, as the cotton seed was disinfected against *Bacterium malvacearum*, which treatment should also kill the spores of *V. alboatrum*. The same author also announces, in subsequent notes, the discovery of *Septoriella oleicola*, a newly described parasite of the olive, and *Microdiplodia capsici*, a new species parasitic on pimento.

Recent Earthquakes recorded at Hamburg

DR. E. TAMS reports that earthquakes have been recorded recently at Hamburg as follows: (1) Nov. 5d. 8h. 55m. 34s. *P* compressional epicentral distance 9,300 km. (2) 5d. 11h. 2m. 24s. *P* compressional epicentral distance 9,300 km. (3) 6d. 9h. 6m. 0s. epicentral distance 9,000 km. (4) 6d. 27h. 50m. 57s. *P* compressional at epicentral distance of 9,000 km. (5) 9d. 9h. 28m. 11s. *P* dilatational epicentral distance 9,100 km. All the times are in G.C.T. These confirm the readings from Kew and Stuttgart given previously and probably refer to an epicentre or epicentres under the Pacific Ocean to the east of Japan.

Acetylcholine Hydrolysis

CONTINUING their work on the kinetics of choline esterase *in vivo*, Clark and Raventós (*Quart. J. Exp. Physiol.*, **28**, 155 and 177; 1938) have compared the rate of hydrolysis of acetylcholine by strips of frog's auricle with the rate of recovery of the heart from stimulation of the vagus nerve. It is suggested that a single stimulus to the nerve releases around each heart cell some 20,000 molecules of acetylcholine, most of which is destroyed by hydrolysis. The hydrolytic process is a relatively slow process, 5–10 sec. being required to reduce the concentration of the acetylcholine liberated to half. The contracture evoked in the skeletal muscle of the frog by application of acetylcholine, similarly, is a long-lasting phenomenon, and the authors consequently doubt the existence in muscle of an enzymic system capable of destroying, within a few milliseconds, the acetylcholine liberated at the endings of a motor nerve.

Flavour and Aroma of Butter

CONTROL of the physical condition of butter is more or less a mechanical function, and large differences in texture are rarely encountered. Flavour and aroma, on the other hand, are determined by a complex of biological, biochemical and chemical reactions and in consequence may vary widely. E. G. Pont has recently discussed some of these problems (*J. Australian Inst. Agri. Sci.*, **4**, No. 3, 131). Generally speaking, butters may be divided into two groups, one being full flavoured, acid and prepared by a starter containing bacteria, the other being mild, slightly acid or even alkaline, for which no starter is required. The former is largely produced in Denmark and many other Continental countries, whereas the latter is manufactured almost entirely in Australia and New Zealand. Fullness of flavour, however, appears to be directly dependent on the diacetyl content of the butter, brought about by the complex fermentation processes induced by the starter. Unfortunately, the series of auto-oxidative reactions do not cease at the desired point, with the result that starter butter has not nearly such good keeping quality in cold storage as the non-starter type. The chief problem, therefore, is to find some means of improving the flavour without reducing the keeping quality. Since diacetyl itself, in the concentrations found in butter, does not actively promote deterioration, there is no fundamental reason why the flavour of the mild type of butter could not be intensified without affecting its other desirable qualities. There are, however, considerable technical and other difficulties in the way, but in view of the fact that on the English market (which absorbs the bulk of the Australian butter) a product with a full flavour always commands the better price, the point is considered worthy of further attention.

Hydration of Vitamin B_1

THE water of crystallization of vitamin B_1 (which is deliquescent) has been variously given as one half, one, or approximately one, molecule of water per molecule of vitamin. W. A. Bastedo, N. R. Trenner and T. J. Webb (*J. Amer. Chem. Soc.*, **60**, 2303; 1938) have determined this magnitude by different methods. They find that the results of dissociation pressure measurements are liable to lack of reproducibly owing to minor details in the preparation of the vitamin, such as methods of removing solvent, etc. Standardized procedures were adopted, but it was found that slight variations in the aqueous pressures to which the samples were exposed gave rise to appreciably variable water contents of the vitamin, indicating that the problem was not one of an ordinary system of hydrates. The degree of hydration corresponded with about 0·4 per cent of water at 1 mm. pressure of vapour and varied continuously to 5·2 per cent at 19 mm. At the vapour pressure of the saturated solution, 20·9 mm., the degree of hydration corresponds approximately to one molecule of water of crystallization per molecule of vitamin.

Paths of Ions in the Cyclotron

IN the cyclotron, particles are introduced near the centre of a magnetic field and are accelerated by a periodic electric field applied between two semicircular electrodes. The particles describe closed circuits in time with the alternations of the field, so that they are accelerated at each revolution and the size of their orbits continually increases. If the velocities are so high that the relativity value of the momentum differs appreciably from *mv*, the time of description of a circuit in a uniform field will increase with increasing velocity and the particles will get out of phase with the electric alternations unless the magnetic field increases radially. It has been shown by Bethe and Rose that a radially increasing field exercises a defocusing action on the ions, causing them to diverge on either side of the median plane. This effect sets a limit to the velocities usefully obtainable with the cyclotron. L. H. Thomas now shows (*Phys. Rev.*, **54**, 580; 1938) that a variation of the field with polar angle may introduce a compensating focusing effect. The required variation is of the order v/c, and the variations considered in the paper are a function of the radius and have period $\pi/2$ in angle. It is shown that the resulting orbits for the particles are stable, and that the focusing obtained is not upset by the presence of the electric field. The Bethe-Rose defocusing limitation on the performance of the cyclotron can therefore be removed in principle.

Molecular Films*

THE forces between molecules of organic liquids of non ionic type are ordinarily of such short range that they act only when the molecules are in contact The magnitude of the force depends mainly upon the area and the nature of, the two contacting molecular surfaces This principle of independent surface action has been a useful guide in the development of theories of surface tension phenomena and should be equally valuable for theories of vapour pressures and solubilities It leads directly to the concept of molecules having hydrophobic and hydrophilic parts which spread as oriented monolayers on a water surface

Such monolayers can have the properties of two dimensional gases, liquids or solids A type of film called a duplex film, having no three dimensional analogue, has two interfaces (an upper and a lower) which are separated by a thin three dimensional layer (the interstratum)

Expanded films such as monolayers of myristic acid on acidulated water are duplex films in which the interstratum is a hydrocarbon liquid The lower interface contains all the hydrophilic groups These, because of thermal agitation constitute a two dimensional gas that exerts a surface pressure causing the expansion of the film

Many proteins, although very soluble in water form remarkably insoluble monolayers which are duplex films The interstratum consists of polypeptide chains which form loose loops attached at intervals to the upper interface by hydrophobic groups These give to the upper interface the properties of a two dimensional gas When the monolayer is compressed some of the hydrophobic groups are driven from the upper interface into the interstratum The irreversible formation of the monolayers indicates that the globular proteins have an entirely different structure and gives support to the cyclol theory

The viscosities and elasticities of monolayers furnish information regarding the cross linkages between the chains

Stearic acid spread on water containing traces of barium salts gives monolayers which can be deposited by a dipping process upon solid plates By successive dips any number of layers up to 3 000 can be built up Optical measurements involving interference of light reflected from the top and bottom surfaces, give accurately the thickness of the film

Single monolayers of various substances, deposited upon barium stearate multilayers of critical thickness (about ¼ wave length) are readily visible to the naked eye because of the change of colour With monochromatic light the thickness of the monolayer can be measured to within about 2A

The barium stearate multilayers are both hydrophobic and oleophobic (non wettable by oil) Dipping into dilute solutions of thorium nitrate causes an overturning of the outside layer of molecules making the surface polar and hydrophilic Such conditioned surfaces can absorb many organic substances from solution giving observable increases of thickness This technique serves as a valuable tool in biological investigations

Free stearic acid in barium stearate multilayers can be dissolved out by dipping the film into benzene containing 1 per cent alcohol, leaving a skeleton of unchanged thickness but of refractive index which may be as low as 1 2 The application of a drop of oil fills the pores of the skeleton without wetting the surface and restores the original colour Films of many substances may be deposited upon skeleton films and the permeability of the deposited films to liquids or vapours can thus be measured optically

* Substance of the Pilgrim Trust Lecture delivered by Dr I Langmuir For Mem R S before the Royal Society on December 8

A Primitive Philosophy of Life*

IT has been rather the fashion of recent years to make too light of what is known as the comparative method in anthropology, used with such effect by Sir Edward Tylor and perfected by Sir James Frazer So much of the work Frazer has done in that field is now taken for granted, that we are perhaps too prone to forget that but for the comparative work done by him much of the intensive investigation into particular areas which is now possible would scarcely have begun to take place In the present lecture, a hypothesis is put forward in regard to certain conceptions on which Sir James has had much to tell us—conceptions of life

That conception of life which forms the subject of the lecture was first thrust on Prof Hutton s attention when investigating the head hunting practices of the Naga tribes of Assam The Karen apparently regard the soul as leaving the body and proceeding to the underworld where eventually it becomes a vaporous substance in a bladder or egg, which bursts, and the contents spread over the fields, fertilizing the developing flower of the rice plant and other herbs of the field This seems to embody a conception of life as a material finite substance—a vaporous matter, limited in form and extent, and on the possession of which the propagation and renewal of life depends It is to be noticed that this condensation of the life substance does not take place immediately after death, but the shade of the deceased continues to exist in a land of shades as a sort of separable soul, before the pupating process, which precedes the next manifestation of the psyche as a sort of fertilizer of vegetation Clearly the belief of the Karens is not rudimentary but has been the subject of speculation and elaboration.

---

* A Primitive Philosophy of Life By Prof J H Hutton (The Frazer Lecture 1938) Pp 24 (Oxford Clarendon Press London University Press 1938) 2s net

This idea of the Karens does not stand alone, but has many parallels, particularly in the Indonesian area. The notion of dew as embodying life seems to be widespread, and was not unfamiliar in Great Britain, for example, in the seventeenth century. One of the most meticulous and detailed beliefs about life-material, or 'soul-substance', is recorded among the Kai of what was formerly German New Guinea. Life-material is there identified with the shadow, the reflection and the personal name, and appears to reside in every part of the body, saliva, excreta, the glance of the eye and even the voice. This idea is not foreign to civilized ideas, for it appears in Plato's "Timæus", and is said to be found in the Taoist philosophy of China, while in the Vedanta philosophy of Hinduism, the body is the exterior of a series of sheaths encasing the soul, of which the interior less material sheaths accompany it on its migrations.

Soul material is particularly strong in certain parts of the body, particularly the head. In San Cristoval, one soul emerges from the head after death, a round stone or fossil being used as a receptacle, in which it is placed among the family gods, or, it may be, in the fertilizing waters of a river. The other part of the soul similarly goes into a sacred stone of a baetylic nature, just as the soul in so many Naga tribes enters the wooden statue on the grave, or the memorial stone erected in the rice fields. A third possible destination for the San Cristoval souls is the mandible of the deceased. Hence the mandible of a dead chief is preserved to bring luck in hunting, or to remind them of the duty of blood revenge. The importance of the lower jaw is widespread in Indonesia, and extends to Polynesia, while in West Africa the possession of the mandible gives power over the ghost.

These beliefs in the selective location of the soul-substance in the head, and its relation to fertility, are basic in the practice of head-hunting. The Kwotto seem to state specifically that the enemy head is abstracted in order to transfer to the decapitator, or rather to his community, the virility and power of the slain, and so to build up a sort of virility-power reserve, to be drawn on as the community requires.

In many instances the life material is in the blood; and Sir James Frazer mentions many instances wherein the blood of the killed is partaken of by the killer, as well as carefully avoided, because it contains the life of the dead animal. The liver, the heart, the brain, or the eye are regarded as seats of life by various races. In parts of Papua a man will choose to eat particular parts of the body to reinforce some weakness of his own; while elsewhere people stand under the platform of the deceased to absorb his qualities by anointing themselves with the putrescent fat. Cannibalism, as an act of mourning, may also arise from this same soul-substance notion, as in Australia survivors are urged to eat portions of their dead, so as not to disturb the camp with their mourning.

That life material is regarded as present in grain is indicated by the abhorrence with which the code of Manu regards the act of pounding or grinding it, while in Indonesia plants are regarded as having soul-substance similar to that of man. Many tribes plant a coconut at the birth of a child, when the soul substance of the child is bound to the tree as it grows up. Similarly in Africa, there are stories of the transference of a soul to a plantain tree by means of the placenta planted at its foot, and in India of the fertilization—pollination as it were—of women from the flower of jasmine, or by the petals of the rose tree growing from the tomb of some long-buried saint.

Human sacrifice is clearly traceable in many cases to this same belief in life as a finite substance to be transferred from one person to another, or to vegetation and livestock. Human sacrifice, it has been pointed out, seems to be particularly closely associated with agriculture. It is possible that the association between the souls of dead ancestors and the crops is to be traced to some practice of collecting wild grass seeds and leaving them by the dead as a provision for the future, and the observation of their germination and growth. It has been suggested that the practice of agriculture may have started in this way. It is therefore not inconceivable that the desire to provide for a crop of food grains may have sometimes led to the slaughter of an individual to afford a good grave.

Another aspect of the idea of life as something concrete and finite is in its separability from the body. Hence it must be conceived in some sort of form, and we find it commonly as bee, butterfly, firefly or beetle. It seems clear then that from this conception may arise a philosophy of the soul, conceived in zoomorphic or anthropomorphic shape, while its situation in various parts of the body gives rise to the idea of a multiplicity of souls. From this the way is open to the development of every form of animism, polytheism, or monotheism, to say nothing of a conception of metempsychosis and a future life. Again, from this source are likely to develop theories of nagualism and lycanthropy, at any rate of the kind found in Assam and West Africa; also the idea that the collective soul of the herd may be specially associated with a single individual, as in Indonesia one animal is the leader, or a *Ficus* tree in a grove is considered the chief, who takes care that the soul substance of the other trees does not vanish. So the leader of a community could be the special receptacle of the communal life material, and totemism, so often associated with the external soul, would then be traceable to the same idea. It is possible that ideas about incest, so difficult to account for, may be derived from the same idea, for exogamy is necessary to amass fertility and life from outside the community; while for kings, incestuous marriage was enjoined, whether in order to keep the tribal life pure, or as Sir James Frazer suggests, to maintain hereditary right to rule, which has been vested in the female line.

A first stage in abstraction leads to the idea of life as a force or power, *mana*, then, perhaps inevitably, to taboo, while one aspect of the soul substance doctrine tends directly to sympathetic magic, as action on hair, nails, spittle, etc., affects the whole, of which it formed a part.

Question arises how did this idea originate. It seems probable that limitations of language have played a part in determining ideas as to life and soul. Primitive language is very rich in concrete terms, but poor in abstract. No doubt the lack of any terms other than concrete ones, representing a similarly restricted mental imagery, has been largely responsible for the idea of life as a concrete finite element and, therefore, for the idea of soul substance.

National Parks

AT a meeting of the Linnean Society held on December 8, the objects of national parks were discussed The immediate cause of the discussion was a letter from Prof J B Cleland, chairman of the Commissioners of the National Park at Belair, South Australia, who asked for "an authoritative definition of a National Park" and an expression of opinion as to how far facilities for sport and recreation should be allowed to replace the original flora and fauna, especially when the Park is near a large city

Prof T G B Osborn, a former commissioner, gave an account, illustrated by lantern slides, of the Park at Belair It is an area of 2,000 acres in the hills to the south west of Adelaide, about eight miles by road from the city Its history as a park dates from 1891, but the area has been preserved in a semi wild state since shortly after the foundation of the Colony in 1837 Formerly known as the 'Government Farm', it served as a depot for horses of the Police and Survey Departments The western end is relatively level, with open eucalypt forest (red gums, manna gums and peppermint) and grassy undergrowth This is the part which has been most influenced by grazing of horses and clearings for sports grounds From this area, which lies at about 850 ft altitude, two narrow, steep sided valleys run into the eastern part, which in one corner reaches 16,000 ft The valley bottoms have been largely cleared of timber, though magnificent specimens of the original gums are left Exotic trees have been planted among them, and the growth of grass encouraged Here again, sport facilities and picnic facilities have been provided Most of the steep valley sides and surrounding hills are relatively unaltered and have a covering of stringy bark or pink gum trees with shrubby undergrowth Some 350 species of indigenous flowering plants and ferns, including about 50 species of terrestrial orchids, have been recorded

An area of seasonal swamp is of special interest as a habitat of the rare lycopod, *Phylloglossum*, and a terrestrial *Isoetes* A measure of the interference with the flora is seen in the 150 species of alien plants naturalized in the Park The indigenous mammalian fauna is probably extinct, but many interesting reptilian species remain Eighty one species of birds have been recorded Like other parts of the Mount Lofty Ranges, the Park is liable to damage from fires during the dry season The indigenous vegetation recovers rapidly after burning, but frequent forest fires open the way to invasion by alien species Grazing by horses helps to keep the grass short, and so reduces the danger of fires during the dry season The Commissioners have not a large grant for maintenance, so they welcome the fees from depasturing horses A considerable addition to revenue is obtained from the hire of sports grounds, tennis courts, and pavilions for picnics

Sir Peter Chalmers Mitchell, speaking on behalf of the Society for the Preservation of the Fauna of the Empire, defined a national park as an area under public control, with unalterable boundaries, in which wild animal and plant life is preserved, and hunting or collecting only allowed under licence He agreed that there is need to modify the definition to meet the case of smaller areas near towns, for it is unreasonable to expect that an area so situated should be left exclusively for naturalists

Dr Julian Huxley pointed out that this definition was meant primarily for Africa As a member of the Standing Committee for National Parks of the Council for the Preservation of Rural England, he emphasized that a national park in Great Britain should be an extensive district of beautiful landscape left in traditional usage Whilst in Africa the preservation of flora and fauna might be the chief object, in England possibilities for recreation, walking and camping in unspoilt countryside must take precedence In his opinion, the Park at Belair in South Australia is too small to fulfil the functions of a national park, but it should be possible to restrict games to certain areas, and to establish sanctuaries in the wilder parts The ideal of a national park for England embracing an extensive district (50–200 square miles) of wilder countryside, was developed by Mr John Dower of the Committee for National Parks The aim would be to preserve the beauty of landscape, allow access to the people and afford general protection of wild life

Dr G Herbert Smith, speaking for the Society for the Promotion of Nature Reserves, said that, small though the Park at Belair is, its use for recreation and æsthetic enjoyment is not necessarily incompatible with protection of flora and fauna

Prof F E Weiss urged the importance of localizing sporting facilities and motor traffic and of maintaining strict reserves within the park for plants of special scientific interest Mr C A Gardner pointed out that one such reserve exists near W Albany, Western Australia, for the preservation of *Cephalotus*, the endemic pitcher plant He emphasized the difficulty of conserving the Australian flora, owing to the fact that it is readily modified by recurrent fires and human access Mr H I Burkill reported an unsuccessful attempt to conserve an area of natural jungle in the Botanic Gardens, Singapore

The inevitability of change was stressed by Dr W T Calman, who pointed out that Nature is dynamic, not static, and that, unless the traditional occupations of the countryside are maintained, the flora and fauna of any reserve in Britain will alter in a few years

Summing up, Dr J Ramsbottom said that the term 'Nation's Park', first used in America in 1842, was intended to mean an area of country left in its 'pristine state'

Replying to the criticism of the inadequate area of the National Park, Belair, Prof Osborn said that South Australia has also a flora and fauna reserve of about 200 square miles at the western end of Kangaroo Island The vegetation and animals of this differ from those of the Mount Lofty Ranges; hence the importance of the small reserve at Belair

Count Kaspar Sternberg, 1761-1838

BORN at Prague on January 6, 1761, Kaspar Sternberg was destined for the Church, and to that end studied theology at Freising and Rome When scarcely twenty-two years of age, he obtained an appointment at Regensburg and gave promise of rapid advancement. Turning his attention, however, to natural science, he began a thorough study of botany in connexion with certain forestry duties allotted to him. He collected and cultivated wild plants and acquired an extensive scientific library In 1810 he published his first monograph, "Revisio Saxifragarum"

In the same year, following the death of his older brother, Sternberg returned to Bohemia, taking his herbarium and library with him From this time onwards he lived alternately in Prague and at his country seat, Březina Castle near Radnice in West Bohemia, maintaining a keen interest in science and supporting its extension and application to local industries He began the agitation for a national museum and became its first president when it was founded in 1818, a post he retained until his death He appointed Palacký as secretary of the National Museum Society, K. B Presl as curator of the natural history collections and later (1836) A J Corda to take charge of the zoological section, whilst Presl was left with the botanical part Sternberg gave his own herbarium and mineral collections to the Museum and also impoverished himself in the purchase of the collections of others to make it as representative as possible. Thus he bought the 15,000 specimens collected by the Bohemian explorer Thaddeus Haenke, and engaged Presl and F M Opiz to classify and describe them, financing their "Reliquiæ Haenkeanæ", which appeared in two sumptuous volumes in 1825 and 1835

At his castle near Radnice, Sternberg amassed a wonderful library, which has passed into the possession of the Bohemian National Museum, and he laid out botanical gardens, including hot-houses for tropical plants The coal deposits of Bohemia were attracting attention at this time and Count Sternberg investigated the formation of coal and described many fossil remains of plants in his "Flora der Vorwelt" (1820-38) which he wrote with the assistance of the Presls and Corda, and which remains a phytopalæontological classic. It was not his first work in this field, for he had already communicated papers to French and German journals on the analogies between fossil and living plants.

Sternberg's interest in the application of science to industry is shown in his "Outline of the History of Mining and Mining Laws in the Kingdom of Bohemia". This monumental work appeared in two parts in 1836 and 1838, and the frontispiece to the first depicts Wenceslas II handing a document of mining rights to miners in 1300, whilst at the end is a map of Bohemia in 1500 showing the centres of gold-, silver- and other mining activities. In the preface he urged the necessity for scientific and technical education as a means of checking wasteful methods in working the mines

Most of Sternberg's works were in German, though he supported what Czech publications there were and he encouraged the printing of text-books and treatises in that language His last public function was to preside at the medical congress at Prague in 1837, on which occasion he advocated the greater application of science in the study of medicine His memory is perpetuated by the name sternbergite assigned to the mineral, an argentiferous pyrites, discovered by Haidinger in 1826

Count Sternberg died at Radnice on December 20, 1838, after a full and useful life.

Air Conditioning in Deep Mines

AT a joint meeting of the Institution of Mechanical Engineers and the Institution of Chemical Engineers held on May 17, a paper entitled "Engineering Problems associated with the Improvement of Temperature and Humidity Conditions of the Atmosphere in Mines at Great Depths" was presented by Dr. J H. Dobson and Dr. W. J. Walker. In it were raised points of world-wide importance in connexion with mining operations which are carried on where wet bulb temperatures of mine atmospheric air approach 90° F. and approximate to normal blood temperatures. The task of the engineer is to produce satisfactory conditions for underground workers in these extremely difficult conditions, and the authors explained the complexity of the problem and gave a brief account of the research which has been devoted to it.

In describing the conditions to be dealt with, the considerable progress made in modifying them and the trend of future developments, the Witwatersrand goldfields were cited as an object lesson by the authors, who presented the subject in broad outlines with the view of stimulating interest in this work and encouraging suggestions towards a solution of the intricacies involved in it. The present working levels at these mines are from 6,000 to 8,000 feet, and Rand mining engineers hold that depths of 12,000 feet are within economic possibilities Owing to the nature of the dust, silicosis has to be guarded against and the wet system of mining is employed. This means that there must be copious supplies of water at the drills, at all working points and wherever dust may occur. This condition, taken in conjunction with the high virgin rock temperatures in restricted spaces with a limited circulation of air, points to the fundamental nature of the problem. To present an idea of the magnitude of the heat inflow, the authors estimate, in relation to a mine at a depth of 6,000 feet from which the monthly output is 150,000 tons of rock, that, from all sources, 70,000,000 B.Th.U. per hour may be expected Of this total a large percentage has to be extracted in order to adapt the underground atmospheric conditions to the health and physical efficiency of the workers

Three methods in operation were described At the Robinson Deep Mine, a surface refrigeration plant is used which deals with 407,000 cubic feet of air per minute, cooling it from 65°/60° F wet bulb temperature to 38°/33° F the cooled air being sent down the downcast shaft to a depth of 7,500 feet Underground refrigeration is adopted at the East Rand Proprietary Mine and the plant treats more than 8,000 tons of air per day, cooling it from 81° to 72° As a contrast to these systems, dehumidified compressed air is used at various mines of the Anglo American Corporation by employing it at every possible machine underground This eliminates one source of heat in the use of electric motors, and from the practical point of view offers a much simpler system at the hot spots than any of the others Devaporization of the air is effected by over compression It is first compressed to 90 lb /in ^{2} abs and then taken to an over compressor where it is raised to 130 lb /in ^{2} abs It next passes through a cooler, the first water separator, the heat exchanger where it is further cooled and a second water separator from which it goes to the expansion turbine Then after passing through a third water separator and the heat exchanger it goes to the compressed air pipes in the downcast shaft

As the wet method of mining is responsible for a substantial portion of the problem presented, the authors also discussed the relative advantages which would accrue from the adoption of drier methods and dealt with the concomitant problem of the prevention of dust

Preservation of Antiquities of South Africa

WITH the view of safeguarding the evidence of antiquity in South Africa, the Minister of the Interior of the Union of South Africa has published orders prohibiting the removal or export of monuments, relics, or antiques without the written consent of the Commission for the Preservation of the Natural and Historical Monuments, Relics and Antiques (Notices No 1571 and No 1572, *Gazette of the Government of the Union of South Africa*, Sept 20, 1938, No 2569, pp 955 958) The orders are made under the provisions of Section 10 of the Natural and Historical Monuments, Reliques and Antiques Act, 1934, as amended by Section 4 of the Natural Monuments Amendment Act, 1937 The antiquities covered are specifically stated to be drawings, paintings, and petroglyphs of the Bushmen, or other aboriginals, or peoples inhabiting South Africa prior to the arrival of the Europeans, implements or ornaments known or commonly believed to have been used by them, and any anthropological or archæological contents of the graves, caves, rock shelters, middens or shell mounds, and any vertebrate fossil Further, the orders cover any objects that have been proclaimed, or are capable of proclamation, as antique

While the Commission thus entrusted with the responsibility of deciding to whom permits shall be accorded under the orders, is most anxious to encourage the exploration of the rich archæological and palæontological fields of the Union of South Africa, and welcomes research by all who are properly equipped, it is determined to do everything in its power to ensure proper investigation and to put an end to such reckless exploitation—often unwitting—as has been all too common in the part With this object the orders now published embody by laws which lay down regulations upon which the consent of the Commission to the excavation or removal of relics is made dependent

These regulations prescribe the terms of the application, which must define the character of the antiquities and their exact location with a locality sketch of the area, and require that after removal the Commission shall be furnished with a description of the objects removed, a statement of their destination, and when the investigation is archæological, a complete set of plans and stratigraphical records Further, the excavator may not dispose of any object without the written consent of the Commission by whom is also reserved the right to retain in South Africa a representative collection of the excavator s finds While the right of scientific ownership is recognized, this may lapse if suitable publication does not follow within such time as the Commission may approve

In order to ensure the proper character and technique of the excavation not only must the application to investigate set out the applicant s credentials, but *also access to the excavation is reserved to the Commission* or its representatives, uncivilized labour must be properly supervised, all material must be sieved through a prescribed size of mesh and photographs of material *in situ*, and of sections of stratified deposits must be submitted with notes to the Commission as soon as possible Finally, not only must a witness section be left intact, but also not more than one half of any known area of a site shall be demolished, removed or excavated without the specific authority of the Commission

The regulations, though drastic, are such as no archæologist could fail to approve It is eminently reasonable that the South African authorities should seek to protect their antiquities from the fate by which other countries too often have suffered, owing to the removal from its place of origin of evidence of value, sometimes unique, of past cultural achievement Even more important is it, especially in a country so sparsely populated and so difficult for supervision, as South Africa, to secure that antiquities are not wantonly despoiled, either through ignorance or through the indiscriminate greed of the curio hunter, but that when they must be made the subject of investigation in the interests of science, their evidence should be made available for the advancement of learning by examination under supervision in accordance with an approved scientific technique and by fully qualified and responsible investigators The provision that part of any excavated site, unless otherwise determined, must be left undisturbed, is especially commendable

Science News a Century Ago

The English Agricultural Society

THE first general meeting of the English Agricultural Society since its formation took place on December 18, 1838, Earl Spencer being in the chair The committee, it was stated, had agreed to publish a quarterly journal of its proceedings and this would contain prize essays. It was desirous of enlisting all the talent it could for the discussion of subjects of deep interest to the practical farmer An award for that year was being given to the Rev. W. Pearse, of Winkfield, Berkshire, for an essay on the cheapest and simplest process for analysing soils. The essays sent in on the origin and progress of the black caterpillar, the present state of agricultural mechanics and the improvement of implements had not come up to the required standard One prize to be given at the Oxford meeting in July 1839 would be for an essay in the cultivation of the soil for cattle and breeding of stock. A veterinary college had long been established in London, and the committee had represented that great advantages would accrue if the College, instead of confining its attention to horses, would inquire into the diseases of cattle, sheep and pigs A favourable reply had been received from the College by the committee

Naval Architects in the Royal Dockyards

UNDER the heading "The Admiralty and the Members of the School of Naval Architecture", *The Times* on December 21, 1838, published a contribution from a correspondent referring to the dissatisfaction among the naval architects who had been trained in the School at the lack of recognition they received The School, which was the first of its kind in Great Britain, was in existence from 1811 until 1832, having been founded as a result of the findings of Lord Barham's Commission of 1806 Those who entered the School had been induced to do so by promises held out by the Government that after proper examinations they would be eligible for the positions of foremen, assistant master shipwrights and master shipwrights in the dockyards An Order in Council of January 30, 1816, had stated that the object of the School was to introduce a better and more skilful description of shipwright officers into H.M Service. Those who qualified were under a bond of £600 to remain in the public service for at least ten years after the completion of their apprenticeship Official countenance, however, was uniformly withheld from members of the School, and out of the last twelve appointments superior to that of foreman, said the writer, only one had been conferred on a past student

The history of the School and the careers of those who passed through it were dealt with by the late Sir A. W. Johns in articles in *Engineering* of March 12 and 26 and April 9, 1926

Technical Education at King's College, London

IN its "Weekly Gossip" column, the *Athenæum* of December 22, 1838, said: "Having so frequently advocated the cause of an improved system of education . . . it is with no little interest that we have watched those demonstrations which have been of late made in London, Durham, Dublin and elsewhere, in favour of methods of elementary instruction having for their basis the great principles of manufacturing and commercial science, and systems proposing to themselves the practical development of these, and their application to the processes of the commercial and manufacturing arts . . . and we are pleased to hear that the Council of King's College, in addition to the well-organised system of instruction to which we lately alluded, have recently added a teacher in Mineralogy; and yet further to determine the practical direction of their course, have at a recent meeting, assigned fees for the formation of one, if not two, additional professorships, of an exclusively practical nature, having for their object the development of the *Economy* of the mechanical arts, and the *Composition* of machinery An arrangement has also been made, as we are informed, by which students who have attained a certain stage of their progress will be secured admission to various manufactories and public works carried on in the neighbourhood of the metropolis."

Discovery of Roman Skeletons

THE *Gentleman's Magazine* of December 1838 contains the following information: "Some interesting discoveries have been recently made at Shooter's Hill, near Pangbourne, Berks, on the line of the Great Western Railway. Several human skeletons, in a high state of preservation, have been disinterned, together with small sepulchral urns, of rude workmanship, but elegant and classical devices, and upwards of 40 Roman coins, of gold, silver and brass of reigns of Domitian, Constantine, Julian the Apostate, Constantius, Gracianus, Licinius or Lupicinius the Pro-Praetor (who was invested with regal authority), and several others Spear-heads, battle-axes and spears of British and Roman manufacture were also found; and some of the graves contained considerable masses of charcoal, without bones The bones are well preserved, having laid in dry gravel, about 4 feet from the surface, immediately over laying the chalk; and one of the skulls appears heavier and more consolidated than is natural"

University Events

DUBLIN.—On December 8, the honorary degree of D.Sc. of Trinity College was conferred on Dr R Lloyd Præger, formerly librarian of the National Library of Ireland, and Prof. E. S. Goodrich, professor of zoology and comparative anatomy in the University of Oxford.

DURHAM—Dr. F A. Paneth, reader in atomic chemistry in the University of London, has been appointed professor of chemistry in the Durham Division, vacant by the appointment of Prof Irvine Masson to be Vice-Chancellor of the University of Sheffield.

LONDON.—Mr. E. R. J. Hussey has been appointed as a third Heath Clerk lecturer for 1938-39.

SHEFFIELD.—The following resignations have been recently received: Dr. Arthur Pool, from his post of lecturer in mental diseases; Mr. A. W. Fawcett, from his post of lecturer in surgical pathology; Mr H. E. Collins, from his post of lecturer in mining.

A D Peacock and **Ann R Sanderson** The cytology of the thelytokously parthenogenetic saw fly *Thrinax macula* Kl The fern living saw fly, *Thrinax macula* Kl in the laboratory at least, reproduces solely by females All male, or predominantly all male broods occasionally appear under parthenogenesis but the males so far appear to be reproductively useless The female somatic and germ tissue constitution is 14 that of the male spermatogonium and spermatocyte counts 7 Autoregulation of chromosome number in the parthenogenetic female producing egg shows only one maturation division non reductional and the formation of only one polar nucleus

Mary H Latham Some Eocene Ostracoda from North West India The collections of Eocene Ostracoda described in this paper were made by Lieut Colonel L M Davies and by Mr Pinfold of the Attock Oil Company The specimens are of particular interest and importance owing to the fact that very few fossil Entomostraca had previously been found in India Both Bairdiidæ and Cytheridæ are especially abundant in beds of Upper Ranikot age in the Punjab and Attock districts It therefore becomes evident that those beds were of a predominantly estuarine facies During the later Palæocene and the Lower and Middle Eocene times Ostracoda became exceedingly rare and small probably owing to the extension of marine conditions

W Peddie Establishment of the trichromatic theory of colour vision The various points on which misunderstanding arose regarding the essential implications of the trichromatic theory were reviewed Inessential postulates were frequently looked upon as fundamental although they were only introduced for purposes of ready description Again postulates introduced only as being the most simple to be retained only so long as no occasion for expansion arose were taken as necessary The latest of these was the postulate regarding the magnitudes of the component colour vectors which has been amended by Schroedinger Three independent stimuli are now universely recognized as sufficient So three sensations follow logically and trichromasy is established

B N Desai P M Barve and **Y S Paranjpe** Importance of dialysis in the study of colloids (5) Colloidal gold (6) Colloidal vanadium pentoxide The cataphoretic velocity of the particles in gold and vanadium pentoxide hydrosols and their tendency to aggregate in the presence of electrolytes are markedly dependent upon the extent to which the sols are dialysed Hence certain apparent anomalies may be attributed to disregard of the influence of dialysis The behaviour of the sols on dialysis and dilution shows that the properties of such systems are not related in the simple fashion frequently postulated In particular, it would appear that the stability does not depend directly upon the magnitude of the particle charge

Ian Sandeman Molecular spectra of the hydrogen isotopes (1) Application of the rotating vibrator model to the states of D_2 Measurements of some of the band systems of deuterium in the visible part of the spectrum are now available from the work of G H Dieke and his collaborators Difficulties raised by the practical application of the theoretical work of the late J L Dunham to the spectrum of the neutral molecule of deuterium are discussed and the constants of two of the molecular states are calculated and compared with those for the corresponding states of the neutral hydrogen molecule It is shown that the potential functions of the two isotopes differ considerably and that the equilibrium internuclear distance is greater for hydrogen than for deuterium at least in one of the states considered The results of the analysis are sufficiently consistent to indicate that in states of the type considered the rotating-vibrator model provides an accurate means of spectral analysis and opens up new avenues for investigation

G N Watson The computation of the error function

T M MacRobert Solution in multiple series of a type of generalized hypergeometric equation Those generalized hypergeometric equations which are of the same type as the ordinary hypergeometric equation have solutions in terms of generalized hypergeometric functions in the domains of the origin and of *infinity* This is also the case for the ordinary hypergeometric equation in the domain of the unit point, but it is not true there for the generalized equations In this paper solutions for these equations in the domain of the unit point are obtained in the form of multiple series

An African Bureau

THE African Survey for which Lord Hailey has been responsible derives no small share of its value from the comprehensive way in which it brings together in readily accessible form information that previously was extremely scattered and difficult to collect On this ground alone, apart from its critical suggestions, the Survey is of immense value to all those concerned with African problems whether in the administrative or economic sphere, in scientific work or in philanthropic or missionary enterprise

The very magnitude of the survey made however with its masses of data, emphasizes the point so strongly stressed in the Survey, that, in contrast with India, where information on such subjects is usually readily accessible, it is very difficult to obtain information on matters which are essential to an understanding of conditions in Africa This difficulty is experienced fairly widely, though to an extent differing in various fields, and being perhaps more conspicuous in regard to political, economic or social developments than in the scientific field Here, of course, the bulletins issued by the Imperial Agricultural Bureaux and the periodicals and reports issued by the medical and other research institutions in Great Britain circulate full information on the progress of scientific investigations in a wide field

Even these publications, however, do not usually distinguish the matters which specially concern Africa and are scarcely to be found collected in any one institution This difficulty is much greater in the other fields The Institut Colonial International issues from Brussels publications which are a valuable source for the documentation of the legislative and similar proceedings of colonial Governments and its periodical sessions have yielded a useful series of discussions on different problems in administration There are also a number of journals devoted exclusively to social, linguistic and similar studies of Africa such as *Africa* the journal of the Royal African Society, or *Congo* and certain journals are published locally in the African colonies In addition to this periodical literature, there is a growing mass of general literature on Africa as well as of studies of special problems Those sources of information are all, however, very scattered, and sometimes, as in certain French and Portuguese territories, are difficult of access The compilation of a comprehensive bibliography, let alone the examination of source material on many African problems is apt to be extremely laborious and expensive

None of the available sources of information on Africa is open to the public All are circumscribed by other purposes and in none of them are African problems considered as the major interest Moreover, the difficulty of obtaining material is frequently accompanied by difficulty in judging its real bearing or value Where, as in Europe or the Dominions, public measures are fully discussed in the Press or in a representative legislature the observer is able to consider facts or statistics in relation to the policy which gives them their significance This advantage is seldom enjoyed by observers of African colonial administrations, where policy is frequently decided in proceedings which are not made available to the public

As regards the applied sciences, as already indicated, a wealth of material is available to the student in the scientific periodicals which the various abstract periodicals of the Imperial

Bureaux assist in rendering available. Here the difficulty lies rather in providing means by which the non-technical inquirer or the administrator can inform himself of the value of the work which is being discussed and its bearing on the practical problems with which he may have to deal The success of a modern Colonial administration depends largely on the use which it makes of its technical departments, and accordingly any agency which keeps the administrator in touch with the contributions made by science to the solution of his problems is of value

These are the reasons which led to the second main recommendation of the Survey—the provision of some effective means for making knowledge of Africa more accessible, not only to the public but also to those interested in the special study of African questions. To this end is advised the institution of an African Bureau, preferably situated in London, and designed on lines which would make it not only a source of information on practically every aspect of activity in Africa, but also a convenient body to maintain close contact with institutions and voluntary organizations in Great Britain and other countries interested in African development The Bureau should be constituted so as to be capable of providing guidance to those who seek to pursue a special study in any subject of interest in Africa, or of placing them in touch with those who are competent to do so.

The scheme contemplates the appointment of a director who should himself have some experience of the requirements of social or scientific investigation He should have as assistants, three specialists, acquainted with African conditions, and with knowledge, respectively, of scientific, economic and social (including administrative) subjects They would publish periodically a survey of contributions to the knowledge of Africa and of events which affect workers in any branch of study. Their main contribution would not be the result of any original study; they would be dealing with information, much of which would be recorded in some form or another elsewhere.

In regard to the assembling of material, a nucleus already exists in the offices of the African Research Survey, consisting of the more important Government reports and a library of important books on Africa. This material, as well as a large number of leaflets and memoranda specially prepared for the Survey, is already classified and filed under appropriate headings, and some of it would be difficult to obtain elsewhere.

Experience must decide how far the Bureau should proceed in assembling a library of literature on African subjects. Particularly in regard to the earlier publications, it may prove unnecessary to duplicate in the library of the Bureau some of the material on Africa already to be found in the libraries of the Colonial Office, South Africa House, the Royal African Society and the Royal Empire Society. It would indeed be of advantage to avoid amassing material unlikely to be used by those concerned with the present-day development of Africa Equally, of course, this material will frequently require supplementing on the foreign side, and it will also be essential, in regard to scientific and technical subjects, that the staff of the Bureau should acquire a working knowledge of the information available in the libraries of the different scientific institutions and of the additions which scientific research is making to it

On this side of the work of the Bureau, an organization such as the Association of Special Libraries and Information Bureaux may well be able to render signal service in the initial stages Some of the most important aspects of the work of the Bureau will, however, be the establishment of contacts, particularly with such institutions in Great Britain as the International Institute of African Languages and Culture or the Royal African Society It may even be possible to establish a common library and to group these three particular institutions in the same building Overseas contacts, however, are equally important, whether with the "Bureau Internationale de Renseignments" of the Institut Colonial International of Brussels or with official and non-official circles responsible for developments in the Union of South Africa, for example

The Survey estimates that the proposal for an African Bureau involves an initial expenditure of about £10,000 a year, including the renting of suitable accommodation, though this expenditure would probably increase as the work developed While it is hoped that the Bureau would receive full support from the British Government, the desirability of control by a non-official body which would be in a position to seek assistance also from Colonial Governments and from other sources is emphasized. The scheme visualizes control by a managing committee, including representatives nominated by the Colonial Office, the Union of South Africa and Southern Rhodesia, the International Institute of African Languages and the Royal African Society. If the proposal is adopted, this committee might well be extended by co-option or otherwise, to include representatives from different branches of science, the International Missionary Council and the like.

The organization of a clearing house of information on these lines should directly assist the application on a much greater scale of existing scientific knowledge in the service of African needs and the solution of African problems at what the Survey describes as the most critical and formative period of African history. Equally it should stimulate further research, particularly the more comprehensive study of the factors determining the nature of its social development, and a more scientific approach to the problems of health and material well-being to which the physical characteristics of the natives of Africa have given rise.

On both these grounds the project claims the interest and support of all scientific workers, and particularly at a time when constructive development on such lines may well hold the key to the solution of the more threatening aspect of the problem of Colonies themselves.

The Science of Slang

A Dictionary of Slang and Unconventional English

Slang, including the Language of the Underworld, Colloquialisms and Catch-phrases, Solecisms and Catachreses, Nicknames, Vulgarisms and such Americanisms as have been naturalized. By Eric Partridge. Second edition, revised and enlarged. Pp. xviii + 1051. (London: George Routledge and Sons, Ltd., 1938.) 42s. net.

A DICTIONARY of slang may at first sight seem to have no special message for readers of NATURE, but it is impossible to turn over the pages of Mr. Partridge's monumental work without realizing how many important and perplexing problems, philological, psychological and social, are raised in the pages of this dictionary. The book provides data that will be eagerly seized on by the students of many sciences.

What is slang? We have somewhere to set a term to definition, and it may be assumed that everyone knows what is meant by standard English. Making this rather large assumption, we know also that there are deviations from the standard which are not to be classed as dialect—deviations which consist in substitutes, generally undignified, sometimes humorous, and sometimes coarse, "for those modes of expression which are employed by persons who value themselves on propriety of speech". Such substitutes are, for the most part, *slang*, and the reasons for their introduction make as difficult a scientific problem as do the philological problems involved in the derivation of the words themselves.

Over and above this, there are jargons developed by groups which desire their speech to remain cryptic—such jargons have been invented by schoolboys, by vagrants, by professional thieves, and not infrequently have in their make-up a considerable element of humour. The desire to use words or phrases which, without being cryptic or necessarily more exact in technical meaning, shall be different (and usually humorously different) from those usually employed gives rise to the slang of certain trades and professions. A massive contribution to Mr. Partridge's dictionary accrues from terms which in some instances, originally standard English, have for reasons not always apparent become coarsened and colloquial and are certainly not used to-day by that class which prides itself on propriety and refinement in speech. Many such expressions possess a Rabelaisian humour and outspokenness which is something of a saving grace; many are frankly coarse *ab initio* and have never appeared in standard English. In dealing with this last-named class of unpleasant terms, Mr. Partridge is at pains to assure us that his method has been to handle them "as briefly, as astringently, as aseptically as was consistent with clarity and adequacy". He is, in short, in this matter, a consistent disciple of his great predecessor, Captain Grose. None of these categories has been neglected by Mr. Partridge. Johnson could say, speaking of the technical terms of various arts and crafts:

> "I could not visit caverns to learn the miner's language, nor take a voyage to perfect my skill in the dialect of navigation, nor visit the warehouses of merchants and shops of artificers to gain the names of wares, tools and operations, of which no mention is found in books; what favourable accident or easy inquiry brought within my reach, has not been neglected; but it had been a hopeless labour to glean up words by courting living information, and contesting with the sullenness of one, and the roughness of another."

Mr Partridge, more fortunate in the accessibility of his sources than was Johnson, has covered a very wide field. His dictionary is enriched, not only with many and varied examples of military, naval and sporting slang, but also with the jargon of the printing and other trades

Of the varieties of slang and of cant which go to make up the dictionary, some possess much greater interest and freshness than others, great interest, for example, is attached to the *back slang* so prevalent in the coster class during the nineteenth century—a jargon in which the constituent words were produced by pronouncing the more important words in a phrase *backwards*. A skilled exponent of the art could reverse a word rapidly in a most remarkable fashion, and would not have a moment's hesitation in giving, say, "summa-toppopy" as the back slang for "hippopotamus", sometimes making the interpretation more difficult by giving the word a humorous twist "like a tol-de-rol, sir, at the end of a chorus". Back slang has given at least one word to colloquial English. "Kool the silop", the cant phrase for "look (out for) the police", obviously provides a well-known and still extant term for 'policeman'

Rhyming slang, which has had a considerable vogue among Thespians and others, offers some curious problems to the psychologist. It is not an easy matter to place the mentality which—apart from the desire to produce a cryptic mode of speech—finds pleasure in such unmeaning rhyming substitutions as "German flutes" for "boots", "Rory o'More" for "door" and the like.

Mr. Partridge carries his learning lightly, so lightly, indeed, as to refer to Browning's famous unintentional misuse of a vulgarism as "the literary world's worst brick" It is remarkable that he should omit any notice of a similar mischance at the first night of the performance of Tennyson's "Promise of May". Mr Pett Ridge recalls the incident in a volume of reminiscences of London in the 'eighties and 'nineties

It is difficult to avoid superlatives in describing Mr. Partridge's massive contribution to lexicography—he has, single-handed, accomplished a feat of scholarship which it seems almost impertinent to criticize We find, in this dictionary, at a rough estimate, some forty thousand entries of slang, colloquialisms, solecisms, nicknames, cant and vulgarisms, accompanied, where possible, with etymological notes, dictionary definitions, indications of the period in which a term was commonly in use, indications showing whether it is obsolete or obsolescent, and symbols such as +1847, meaning "in significant first use then, but still extant" and −1847, meaning "known to exist then, and presumably used some years earlier". In these matters uniformity of practice is of considerable importance, and it does seem rather unfortunate that, in the use of the negative sign, Mr. Partridge should not have subscribed to the usage of the Oxford Dictionary in which "the latest limit of an obsolete word or sense is shown by means of the year preceded by a dash, as −1759"

It would convey a completely erroneous impression were one to devote a disproportionate amount of space to the few omissions and inaccuracies which have caught the eye of the reviewer, but there are one or two points which Mr Partridge may see fit to consider when a third edition of the dictionary is contemplated

The entry "gas and gaiters" carries the definition "nonsense; . . . exaggerated rubbish; from *ca* 1928" Is it possible that Mr. Partridge has forgotten the existence of the old gentleman in small-clothes and of his advances to Mrs Nickleby? "My love, my life, my bride, my peerless beauty! She is come at last—at last—and all is gas and gaiters!" Equally surprising, too, is it to find a "modest quencher" defined as a "small drink" and dated *ca* 1860. The immortal phrase is Mr Richard Swiveller's, and the modest quencher is anything but modest Even if Dickens is dated nowadays, that generation has lost much which has never repeated and relished:

"I go. Untaught and feeble is my pen,
But on one statement I may safely venture
That few of our most highly gifted men
Have more appreciation of the trencher
I go. One pound of British beef, and then
What Mr. Swiveller called a 'modest quencher',
That, home-returning, I may 'soothly say'
'Fate cannot touch me; I have dined to-day'"

Turning to less literary slang, we find the dictionary defining "fixed bayonets" as a brand of Bermuda rum and dating the term as late nineteenth-early twentieth century. This may very well be, but the late Nathaniel Gubbins, who had an intimate knowledge of mid-nineteenth century Indian military slang, had no doubts about it The term then referred to an awe-provoking dish of chicken stewed in rum.

In dating the phrase "I don't think" as 1837 and in giving a reference to Pickwick, Mr. Partridge follows the lead of the O.E.D. I find, however, that the phrase "You're a nice man, I don't think" occurs in Moncrieff's operatic extravaganza "Tom and Jerry", a dramatization of Pierce Egan's "Life in London", which was staged in November 1821. It would seem, then, that we can antedate the account given for the first appearance of this phrase by some fifteen or sixteen years.

References to music hall and other songs are very often helpful in dating a catch phrase and might be recorded more often than they are By Jingo', 'twiggy vous', 'not for Joseph' and Jim Crow' are relevant instances

The article *s v* non me' elucidates the phrase by a reference to Queen Caroline s trial whereat the Italian witnesses said *non mi ricordo* (I don't remember) to every important question' The reports of the trial put this phrase constantly on the lips of one witness only Theodore Majocci who was flustered by Brougham s cross examination The point is a minute one, but dictionaries and dictionary makers specialize in such matters

The editor's learned note on all my eye and Betty Martin" might well be enriched by de Morgan s adaptation of the phrase (' all ocular and Elizabethan) the delightful military slang of guessing stick ' for slide rule is overlooked and Mr Justice Hawkins appears under a novel title and name as Judge Sir Frederic Hawkins

These are however trivialities , and no one can use extensively Mr Partridge's work without feeling that it is in the ranks of the great books It naturally owes much to its predecessors but much has been added and many errors corrected Its genial scholarship classes it with Grose It supplants Farmer and Henley and the philologist, psychologist and sociologist will find in it an inexhaustible quarry of raw material

ALAN FERGUSON

A Catalogue of the Steroids

The Chemistry of the Sterids
By Harry Sobotka Pp xiii+634 (London Baillière, Tindall and Cox 1938) 38*s*

THE effort directed towards steroid chemistry in all its guises since, and as a consequence of, the introduction of the Rosenheim King formula in 1932, has led to a rapid multiplication of the steroids, so much so that there are now described in the literature nearly five thousand interrelated derivatives of *cyclo* pentenophenanthrene The main purpose of 'The Chemistry of the Sterids is to present a systematic classification of the more important of these derivatives recorded before January 1 1937 together with their physical constants and references to the original literature The classification is extremely successful, for by the introduction of an ingenious system of arrangement based upon the number of ethenoid linkages, hydroxyl, carbonyl and carboxyl groups the matter has been rendered easily accessible In presenting this catalogue the author has considerably lightened the task of approach to the steroid literature

The catalogue occupies nearly five hundred pages, the first part of the book (161 pages) being devoted to a descriptive account of steroid chemistry The early chapters deal with history methods and results of structural investigation A very welcome chapter is concerned with choleic acids and other molecular compounds of steroids Another on steric considerations has the unavoidable disadvantage, common to reviews of rapidly moving and incomplete fields of endeavour, that several important memoirs have appeared since the manuscript was completed A chapter on physical properties gives a summary of crystallographic data and a table of ultra violet absorption spectra It is rather unfortunate that in this table only the maxima and not the corresponding intensities are quoted The book concludes with a collection of some four hundred formulæ which serves as a companion to the catalogue and to the text and to which reference is freely made in both Various errors which have been detected in proof reading have not been adjusted in the diagrams but are carefully recorded in the legends

The general impression gained by a perusal of this text is that a task characterized by its multiplicity of detail has been faithfully accomplished that here is a text which will be welcomed by those directly concerned with steroid chemistry and will supplement the recognized catalogue of organic chemistry

The book has given birth to the word sterid', which in the opinion of the reviewer is ill advised to say the least According to the author, it is meant to comprise sterols and steroids, *i e*, sterol like substances " The word 'steroid' introduced by Callow and Young has been defined as a generic name for the group of compounds comprising the sterols, bile acids, heart poisons saponins, and sex hormones", and though this definition requires modification, the usefulness of the term was immediately recognized and adopted by most investigators The term 'steroids' includes the sterols, so we greet 'sterid' coldly as befits '*jargonese*' all this apart, 'sterid' is devoid of the euphony of steroid'

The Newer Human Morphology

Les Types humains

Par Eugene Schreider Première Partie Les Types somatiques raciaux morphologiques constitutionnels Pp 104 + 8 plates 20 francs Deuxième Partie Les Types psychologiques tempéraments caractères types d orientation générale de l esprit types psychanalytiques types réflexologiques types psychosociologiques Pp 79 18 francs Troisième Partie Les Types somatopsychiques variétés neurovégétatives constitutions somatopsychiques biotypes et variétés endocrinologiques types criminels Pp 105 + 5 plates 20 francs (Actualités scientifiques et industrielles 495 496 and 497 Biologie du travail et biotypologie 3 4 and 5) (Paris Hermann et Cie 1937)

THE study of the diversities of mankind is passing through a transition time in which each worker probably sees only a part of the change that is going on and can but bear honest witness to what he sees Measurements of populations leading to calculations of means and standard deviations and complicated by the creation of various coefficients have proved disappointing and at times have led to obviously incorrect results regarding relationships besides obscuring the biological fact that persons diverse in many ways appear in a population generation after generation through direct inheritance Descriptions on the other hand by means of reference to abstract types sometimes the creation of statisticians rather than the results of biological observation have also proved themselves to be misleading Yet the diversities noted by Retzius Blumenbach and others who have followed them obviously have meaning—long heads of various kinds short heads also of various types with facial diversities and so on in each case remain important—and even if such characters as skin colour have a different kind of biological history they must obviously enter into descriptive schemes

For the moment it seems wise on one hand to try to see what groups of characters often occur together in individuals and to study the distribution of such groups of characters but it is likely that diverse groups of characters are but the outward and visible indications of deep internal diversities whether what are called constitutional or what are thought to be endocrinological Many attempts have therefore been made to describe constitutional varieties of mankind and critical reviews of many of these attempts are the main contents of this work after a brief and not very interestingly compiled review of race classifications has been given

Special attention is given to the classification of the French school of constitutionalists led by Sigaud and especially MacAuliffe These observers seem satisfied with simple Lamarckian interpretations of the phenomenon of adaptation which is to them as to many others who do not quite share their point of view the most important fact in biology Their classification of types however does not really depend upon these interpretations It divides the French male population into respiratory digestive muscular and cerebral types covering respectively about 30 per cent (chiefly in the mountain areas) 14 (especially in Lorraine Normandy and French Flanders) 47 and a variable number from 7 to 25 per cent but it is recognized that vast numbers cannot be put completely in one or other group In each group there are eugenetic persons in whom the predominance of one or another of the systems is only moderate there are others called irregular persons in whom that predominance is exaggerated

Face and body are supposed to be linked and the face is said to have an upper or cerebral an intermediate or respiratory and a mandibular or digestive zone The athletic type apparently has a moderate development of all three One cannot but suggest such difficulties as that many distinguished intellectuals are far from approaching the definition given by MacAuliffe of the cerebral type A revised version of Kretschmer s classification divides constitutions into *leptosome* with height and length (vertical structures) developed more than breadth (horizontal structures) *athletic* with more balanced development and *pyenic* types emphasizing breadth rather then height Kretschmer s *asthenic* types are exaggerated leptosome forms and the term displastic is used for persons with markedly exaggerated characters Kretschmer gathers temperamental differences around the terms cyclothyme and schizothyme The first the extroverts of Jung are commonest among pyenic types according to Gourewitch and Ozeretzki The second the introverts of Jung are commonest among leptosome types but are found also among the athletic types few of whom are found among the cyclothymes

It is evident that MacAuliffe s digestive type and Kretschmer s pyenic cyclothyme have a good deal in common as have the muscular and athletic types of the respective authors but for the present the schemes of classification remain quite separate The attempts of the Italian authors

Viola and Pende to define constitutional types by measurement are discussed in detail and there is a considerable bibliography

These little books are thus a useful guide to several new attempts to understand the diversities of mankind the more useful perhaps because the author keeps his own preferences in the background The new morphology is trying to penetrate into the depths of causation and to find linkages including linkages between physical and psychical It suffers as work on human diversities has always suffered from the well nigh impossibility of establishing genetic sequences that can be adequately demonstrated It also needs to be more careful than have been the racialists not to try to classify by subdividing in such a way as necessarily to find a niche for each individual of the sample under consideration Further it needs to remember that these types are perhaps really growth tendencies and that their distinguishing features may not be purely and fully heritable Typology in mankind is a subject on which satisfying conclusions are notoriously difficult to reach more difficult than ever since race prejudice involving cruel treatment of Jews and others has spread so widely

French Colonial Petroleum Resources

Les ressources minérales de la France d outremer 5 Le pétrole (Publications du Bureau d études géologiques et minières coloniales) Pp iii +263 (Paris Société d Éditions géographiques maritimes et coloniales 1937) 45 francs

DURING the last few years the Bureau d Études géologiques et Minières coloniales has published four bulletins on French colonial mineral resources These concern coal iron zinc and lead and phosphates respectively Now a fifth and final bulletin of the series on petroleum is available The introductory chapter to this bulletin contains a description of petroleum deposits in general with special reference to geological conditions necessary for their accumulation migration and distribution This is followed by a concise exposition of present day methods of exploration to enable the reader to appreciate what has already been accomplished in this direction in French Colonies also what still remains to be done

Tectonically Morocco has proved very difficult from the point of view of exploration Nevertheless in spite of interruptions due to frequent warfare and other misadventures much progress has already been made and an extensive programme of research is being followed Existence of important petroleum deposits has not yet been proved in Tunis and Algeria but numerous surface seepages point to deep lying pools and there is certainly justification for continuing systematic exploration of this vast tract of unproved territory The geology of French equatorial Africa is as simple as that of North Africa is difficult but unfortunately the equatorial forest is an ever present obstacle against which prospectors must battle Exploratory work must therefore necessarily be slow Nevertheless great strides have been made during the last four years and it is considered worth while combating physical difficulties if there is any chance of substantial petroleum deposits being discovered

Madagascar is geologically different from any French African possessions and cannot therefore be grouped with them Petroleum exploration in the island is however so comparatively new a venture that there are few actual results to report All that can be said at present is that a programme of exploration has been drawn up which is being followed with great pertinacity

In Syria no systematic search was made for petroleum until well after the Great War and even then it was only because of its proximity to Iraq that its potential importance was appreciated In fact no real programme of investigation was adopted until 1933 Although Iraq does not belong to France it plays an important part in supplying France with liquid fuels and for this reason together with its proximity to Syria its position is reviewed in conjunction with Colonial resources proper

As a conclusion to this bulletin a chapter is devoted to France s present economic position in the world petroleum market interesting details being given of consumption and imports

A bulletin of this description is bound by its very nature rapidly to become out of date Accordingly so that its usefulness may be extended the Chronique des Mines Coloniales has undertaken to supply statistics and details of geological investigations from time to time as research and mining proceed Further a series of short articles is to be published by the same authority as occasion arises describing the position in the mining industry of each of the countries under French rule In this way it is hoped to direct attention not only to results already achieved in French Colonies but also to possibilities of future development of natural mineral resources

Hints to Travellers

Eleventh edition. Vol. 2. Organization and Equipment, Scientific Observation, Health, Sickness and Injury Edited by the Secretary with the help of many Travellers. Pp. xv+472 (London Royal Geographical Society, 1938) 14*s*

THE new edition of this second volume of "Hints to Travellers" is to all intents a new book. Former editions treated of little besides medical and surgical care and hints on the scope and methods of scientific inquiry These matters are not neglected and the sections dealing with them have been recast In addition, however, there are thirteen chapters on organization, clothing, equipment, food transport, etc, in fact on every aspect of the fitting out and management of an exploring party This is perhaps the most valuable part of the book, for it embodies the experience of many different travellers of recent years.

Polar travel looms large, but then, as the editor says, it marks a present trend in exploration, and so must command attention Moreover, it is in polar travel that the technique has changed most in recent years There are many extracts from the writings of recent travellers which may appear to occupy much space in a book the bulk of which must be kept within small dimensions for the sake of the traveller. On the other hand, these extracts have been carefully chosen, and each stresses some matter of importance even if it is a detail easily overlooked. Food and food values receive much attention, and photography has a long section. even the narrative volume of the expedition, written on its return, is not ignored

The volume is valuable in every chapter, an indispensable handbook for any traveller off the beaten track and an expression of the care and critical judgment of its editor

Railways To-day

By J. W Williamson. (The Pageant of Progress Series.) Pp 160+23 plates. (London, New York and Toronto. Oxford University Press, 1938.) 3*s*. 6*d*. net.

MR. J W WILLIAMSON will be known to many men of science as the former secretary of the British Scientific Instrument Research Association He has a facile pen and also hobbies, one of which is the study of railways and their working. The opening chapter in the book under notice touches on conditions of transport in Great Britain during the sixteenth century, the development of roads in later years and eventually of the 'rail way', from which the modern railway arose early in the nineteenth century Succeeding chapters discuss individual aspects of railway transport, such as the track, the locomotive, building and repairing rolling stock, signalling, operating traffic, traffic control, and so on, with a concluding chapter on electric traction The book is well illustrated with plates and explanatory diagrams. To the mechanically minded boy, and also to those of his elders who still regard the railway as something more than a necessary means of transport, it will be of absorbing interest.

The Nature of Man:

Studies in Optimistic Philosophy By Prof. Élie Metchnikoff. The English translation edited by Sir P Chalmers Mitchell Revised and brought up to date by C. M Beadnell Pp xviii+210. (London · Watts and Co., 1938) 5*s*. net.

WE welcome the new edition of this lively and attractive work, of which the first translation appeared thirty-five years ago (see NATURE, **70**, 394, 1904). The book has been ably revised by Rear-Admiral C M Beadnell, who in addition to several footnotes has added appendixes dealing with artificial insemination, blood transfusion, ages at marriage, illegitimate births in different countries, suicide, infant mortality and other matters. The work begins with a historical sketch showing that while natural philosophers in all ages have sought the foundation of morality in human nature itself and have held human nature to be good, many religious doctrines, especially Buddhism and Christianity, have depreciated the body as compared with the soul.

In the following chapters the harmonies and disharmonies first among beings inferior to man and then in the human race are discussed, special attention being paid to the disharmonies in the organization of the digestive and reproductive systems, as exemplified by the presence of rudimentary organs and disharmonies before and after marriage The part played by science in combating disease is then considered, and the final chapters are devoted to the scientific study of old age and death, which the author maintains will probably bring about great modifications in the course of the last period of life

Human Powers and Their Relations

By K W Monsarrat Pp xvi+289 (Liverpool University Press of Liverpool, London · Hodder and Stoughton, Ltd, 1938) 10*s* 6*d*. net

THIS book offers an excellent example of constructive thinking in theoretical and practical philosophy The problem of knowledge forms its central theme, and is taken as the basis of a more rational organization of human relations. Knowing is conceived as a process which produces and presents reports or ideas The proper use of ideas leads to the conception of the world in terms of power, and not in terms of matter. The classical dualism between power and matter should not be referred to the world as such, but to a duality in the relations of the process of knowing.

Applied to social problems, these views involve the consideration of the world as composed of diverse power-items which compensate each other without fusion in assemblies or associations: the human being is thus conceived as an example of influence-assembly, which retains his freedom and individuality. Society is the combination of human beings according to the same metaphysical process. The interest of these views, as we understand them, is to be found in the conception of an idealist philosophy which preserves the relative independence of the individual. In contrast with the misguided application of idealism by totalitarian States, the vision implied in this book will be found both useful and refreshing. T. G.

Archaic Vertebrates and Evolutionary Principles

By Prof J Graham Kerr, F R S , M P

RECENT attendance at the discussions of the Institut International d Embryologie and of the British Association (Section D) has impressed on me the desirability of offering—more especially to the younger generation of researchers in zoological science—a short statement of personal experience emphasizing certain general considerations which are in my opinion useful as affording guidance along profitable lines of investigation and at the same time warning against dangerous pitfalls I have been in my time responsible for a considerable number of new facts and theories relating on one hand to the evolutionary history of vertebrates and on the other to the general theory of evolution I will not burden this note with bibliographical details but refer anyone interested to my text books on Vertebrate Embryology (Macmillan 1919) and Evolution ’ (Macmillan 1926)

I may say that in my research work I have owed much to the foundations on which I was able to build—a sound training in mathematics and physics experience of fossil collecting among the carboniferous rocks of central Scotland and a *quite unusual training in field natural history* when living among the primitive Natokoi Indians of the Gran Chaco Indications of my early interest in field natural history will be found in my various communications printed in the *Ibis* during the nineties of last century I allude to this preliminary training for it may perhaps be taken as explaining at least in part my somewhat unfashionable attitude towards the branches of science I have mentioned—an attitude sometimes disrespectful towards the mathematical treatment of complicated biological phenomena which have not been subjected to the preliminary analysis into simple components essential to make them amenable to mathematical treatment a somewhat critical attitude towards pronouncements of palæontologists based upon the inadequate foundations provided by a study of skeletal structures in ignorance of ‘soft parts’, and finally an attitude of what may have seemed over emphasis of the need in all evolutionary speculation of paying due regard to each one of the three factors (1) structure (which alone provides actual *records* of evolutionary history), (2) function and (3) natural environment

The Cambridge school of zoology, in which I received my later training, was then at an important stage of its evolution the old school of natural history having sprouted out into a luxuriant new growth of laboratory activity under the stimulus of Balfour and Foster Regrettably but unavoidably the two great branches of laboratory activity diverged as they grew that of physiology on one hand with Foster Gaskell Langley Sherrington and the rest and that of morphology on the other with Balfour and his successor Sedgwick and a galaxy of colleagues of the highest distinction The splendid zoological laboratory of to day—an imposing memorial to the tenure of office of Prof Stanley Gardiner—represents what in its early days was called as it actually was the morphological laboratory

The remarkable Tripos course in zoology in those days in addition to providing a vast amount of knowledge regarding the comparative anatomy and embryology of the main groups of the animal kingdom exercised naturally a strong directive influence on those who passed through it In my own case this directive influence was affected by the recognition of two important weaknesses in the school of morphology (1) the tendency to concentrate attention *on preserved specimens* to the neglect of physiological and environmental conditioning factors and (2) the fact that the body of observations out of which the edifice of morphological theory had been built had been gathered not from such animals as from their admittedly archaic character might be expected to yield reliable information regarding earlier evolutionary stages, but from such as happened to be easily accessible to the investigator From this latter consideration came the determination to concentrate my life work in research upon archaic animals in spite of the technical obstacles in the way As my immediate interest lay in the problem of the evolution of land vertebrates or tetrapods it was to this problem that I proceeded to devote my attention

Of the various types of tetrapod actually surviving at the present day and therefore available for morphological study apart from mere osteology the most archaic seemed undoubtedly to be the urodele amphibian Of the evolutionary stages antecedent to the tetrapods or land vertebrates on the other hand, the most archaic surviving representatives seemed undoubtedly to be the sharks, the crossopterygian ganoids, and the lung fish The lampreys and hagfish I left on one side as liable to mislead owing to their adaptation to abnormal semi-parasitic habits. As regards my own research work, I determined to concentrate upon the crossopterygians and lungfish, not because I regarded them as more primitive than the selachians, but simply because our ignorance of them—particularly of their ontogeny—was more profound. The programme which I set myself, was the investigation of the three genera *Polypterus*, *Lepidosiren* and *Protopterus*—the embryology of which in particular was then entirely unknown—in order to see to what extent they supported or contradicted the accepted canons of vertebrate morphology. I need not refer here to the carrying out of that programme or to the tragic loss to science which it involved in the premature death of that splendid naturalist John Samuel Budgett, who had taken over the *Polypterus* part of the programme.

The study of these archaic vertebrates proved a fascinating task as it provided solutions to many puzzling problems of vertebrate morphology. To take, for example, one organ system alone—the blood system

Why does the headward end of the embryonic heart in the tetrapod assume that spiral twist which results in the common pulmonary artery of the adult amniote having a diagonal position, running forwards from right to left, across the root of the systemic aorta ?

What is the explanation of the reduction of the fifth aortic arch in the Amniota ?

Why did the main stream of blood from the hinder parts of the body in the Amniota come to be carried forward by a new vessel, the posterior vena cava, in place of the original posterior cardinal veins ?

Such are examples of morphological puzzles which found their solution in the developmental phenomena of *Lepidosiren*.

Incidentally, these investigations convinced me that real progress in the advancement of evolutionary theory is to be made through the careful investigation of particular organ systems rather than by speculation regarding the ancestral origin of particular taxonomic groups. They have also provided useful warnings as to pitfalls in the way of the morphological investigator, the non-recognition of which has frequently helped to inflict undeserved discredit on morphological science as a whole.

One of these is, strangely, forgetfulness of the elementary fact that all scientific theories are simply working hypotheses, fitting the knowledge of the moment, to be discarded or modified in immediate response to the requirements of new knowledge. The neglect of this principle has made itself conspicuous again and again. An excellent example is concerned with the mode of development of nerve fibres in the Vertebrata. The view I had been taught was that the nerve fibre, already fibrillated, grew out from the central nervous system and joined up secondarily with its end-organ, muscle-fibre or what not. Investigation of embryos of the large-celled *Lepidosiren* demonstrated that this was not the case, and that the appearances which at first sight appeared to support the accepted idea were deceptive. As it is clearly against all probability that the method of nerve development in vertebrates is not fundamentally the same throughout, it might have been expected that the alternative conclusions would have been obvious to all—either that the accepted theory was wrong, or that the observations that contradicted it were erroneous. It might have been anticipated that neurologists would have hastened to check the observations for themselves As a matter of fact, during the twenty years or so before the preparations succumbed to the wear and tear of student demonstrations, only one single neurologist made his appearance to do so—Elliot Smith He duly satisfied himself as to the accuracy of the observations on the motor nerve trunks of *Lepidosiren* and was good enough to check the general principle involved by extending them to a sensory trunk, the olfactory nerve.

While this experience with the nerve trunks of *Lepidosiren* exemplified well the sterilizing influence of dogma in restraining the recognition of awkward new facts, the same investigation of nerve development soon directed attention to another type of pitfall, namely, the tendency to place too implicit reliance upon one particular technique. This was provided by Harrison's basic experiment in which he showed embryonic nerve rudiments growing freely through a culture medium. The careful study of sections of embryos of *Lepidosiren* showed no reason to doubt the accuracy of Harrison's results so far as mere observation went, but on the other hand did show that in the actual body of the embryo the nerve trunk, instead of terminating in a free end, was already in continuity, as a simple protoplasmic bridge, with its end-organ, in this case a muscle cell, at an extremely early stage in development when the myotome had not yet begun to recede from the spinal cord ; and that accordingly reliance upon the experimental method without applying the check of different technique was apt to lead to erroneous conclusions.

This need of checking by the use of different technical methods, frequently impressed itself during the study of sections of embryos, when it was found necessary to check the evidence of paraffin sections by celloidin or conversely.

Still another and a peculiarly prevalent source of error lies in the tendency to base broad evolutionary generalizations upon the inadequate base provided by the knowledge of only a single organ-system. This is illustrated in particularly flagrant manner by conclusions based on knowledge of the skeletal system. The study of histogenesis in *Lepidosiren* was instructive in emphasizing the curiously vague way in which skeletal stiffening gradually spreads through the embryonic connective tissue—in striking contrast with the well-defined units which go to build up, say, the muscular or renal system. It is well also to recall in this connexion the readiness with which skeletal tissue, such as bone, develops secondarily in the living body in response to merely mechanical factors, as is well known to surgeons in the case of the human being. It is indicated that the greatest caution must be exercised in drawing phylogenetic conclusions from skeletal facts

In the critical frame of mind induced by such considerations, it is astonishing to note the frequency with which palæontologists have allowed themselves to base the most far-reaching evolutionary conclusions upon a basis of purely osteological fact. The suggestion that the resemblances in general form of the skull and in the dentition between a Tasmanian wolf and a member of the Canidæ indicate genetic affinity would be recognized as absurd; these striking resemblances are recognized as indicative simply of convergent adaptation to similar modes of life. Yet similar resemblances in skull structure between certain mammals and certain extinct reptiles have been taken as indicating the evolutionary origin of the group Mammalia from such reptilian ancestors. The fact of the matter is, of course, that far more complete knowledge than is at present available—not merely of the skull but of the whole skeleton—would be necessary to identify the ancestor of the Mammalia, and even should this ancestor be in the distant future identified, it will still be impossible in the absence of information as to its organs other than the skeleton—such as, for example, its heart and main blood-vessels and its reproductive arrangements—whether it can safely be regarded as falling within the boundary of the group Reptilia.

Another shortcoming which frequently invalidates the conclusions of the less thoughtful palæontologists is the failure to appreciate physiological considerations. Striking examples are seen in speculations on the phylogeny of cephalopods based entirely on shell structure and ignoring the immensely important flotation effects of the gas in the chambers of the shell.

Equally striking are the efforts still made to bolster up the Balfour theory that the pectoral and pelvic limbs of the vertebrates are persisting and enlarged portions of a once continuous structure along the side of the body. Long ago it was shown that the embryological foundation of this theory was unsound. Later on, it was shown to be not merely unsound but also erroneous. But still it survives, its supporters unmoved by the physiological considerations which make it entirely improbable. One fact alone, that in every vertebrate the muscular system is in its early stage composed of segmentally arranged myotomes, indicates clearly that the primitive mode of movement of the vertebrate was propulsion through a watery medium by waves of lateral flexure passing back from the head region, and a full appreciation of the perfection of this method of propulsion is sufficient to indicate that the evolution of a new type of motor organ in all probability had to do not with swimming but with making use of solid features in the environment to lever the body forwards The detailed investigation of the external gills of *Polypterus*, *Lepidosiren*, *Protopterus* and urodele amphibians has disclosed the existence within the phylum Vertebrata of a type of organ which possesses the full potentiality of giving rise in the course of evolution to a purely motor organ or limb Nevertheless, we find many palæontologists still ignoring such considerations and quite unnecessarily making use of the Balfour theory to provide interpretation for fossil fragments such as those of the ancient shark *Cladoselache*

Another old-fashioned idea which is allowed to persist in spite of its being untenable in the light of modern knowledge is that which derives the lung of land vertebrates from the air-bladder characteristic of teleostean fish. This no doubt seemed a natural enough idea to those whose freedom of vision was effectively blinkered by the general principle that land animals have evolved out of aquatic, and who did not pause to reflect that the teleostean fishes form the terminal twigs of a branch of the Vertebrata showing the highest degree of evolution for a free swimming existence and inseparably linked with this mode of existence.

What we now know, however, of the comparative anatomy and embryology of air-bladder and lung in the archaic vertebrates leaves no escape from the startling conclusion that the air-bladder of the teleostean fish, instead of representing a condition ancestral to that of the typical lung, is to be interpreted in exactly the opposite fashion. The evidence is, in fact, convincing that the air-bladder of the teleost is the modified right lung of an air-breathing ancestor.

I should not conclude this article without again directing attention to the fact that one of these archaic vertebrates, namely, *Lepidosiren*, happens to possess a character in the relatively enormous size of its cellular and particularly nuclear structures which renders it of unusual value for the study of histogenesis and especially gametogenesis. It was a delightful, though distracting, experience to observe for the first time the beautiful mitotic figures of *Lepidosiren* in those days when Cambridge teaching was still sceptical regarding the existence of centrosomes! The value of *Lepidosiren* material for the investigation of cell-detail is well brought out by the beautiful studies on the histogenesis of the blood by Bryce, on microgametogenesis by Agar, and on neurone relations by Ballantyne. The last-mentioned provides a typical case of new facts which, if they are really facts—and that they *are* facts, accurately described, I can personally testify—are shattering to one of the most sacred beliefs, for neurofibrils can be clearly seen to pass across the synaptic junction and plunge down into the cell-body of the next neurone

Various ideas of a more general kind bearing on the principles of evolutionary theory have been inspired by these researches that variability is to be regarded not as a phenomenon by itself but merely as one aspect of the general instability inherent in all living substance, that the selection of variations in a definite direction necessarily involves the selection of the *tendency* to vary in that particular direction, and therefore necessarily results in 'orthogenesis', that the phenomenon of parasyndesis discloses the existence of an attractive force which draws *like* chromatin together, and that this, while explaining the clumping together of like chromatin at successive points in the chromosome, renders unnecessary the assumption that the material basis of heredity consists of discrete and separate units or 'genes'

Finally, I would urge, my prolonged experience in research has served to emphasize a consideration that is too often ignored, namely, that it is not sufficient to be content with making use of newly determined facts simply as arguments for or against already existing theories On the contrary, it is essential that from time to time there should be a stock-taking, in which the body of relevant facts as now known is examined from a detached point of view, and the endeavour made by judicial consideration to arrive at a sound conclusion as to what general formula adequately fits the knowledge of to-day

---

Food Storage and Research

THE report of the Food Investigation Board describes the general activities of the Board and, in summary form, the scientific researches carried out by the members of the food investigation staff, under the general direction of Mr E Barnard, the director of food investigation * References are given to published work, but the special purpose of the report is to record the latest progress in those investigations which have not yet reached the stage at which full publication of the results is feasible

Sir Joseph Barcroft was appointed chairman, on the resignation of Sir Frank Smith Mr Blackman, Prof Hilditch and Sir Thomas Middleton were re-appointed members of the Board Two special reports have been published, the first by R B. Haines, summarizing the more important data relating to the invasion of animal tissues by micro-organisms and their control (Special Report No 45), and the second by C. H. Lea on rancidity in edible fats (Special Report No 46).

Members of the food investigation staff paid visits to South Africa, Germany and the United States and Canada during the year Broadly speaking, the impression which the Board has gained from the report on the American tour is that while Great Britain is in no way behindhand in research on the handling and storage of foodstuffs, the application of science in this field is not so forward here as in the United States There, the active belief of the leading industrialists in the value of research, and their keenness to apply scientific method and knowledge in the food industry were striking, and so was their readiness to spend large sums in developing new processes and in introducing new products to the public.

Reference is made in the report to the recommendation of the committee appointed to review the scope and form of the "Index to the Literature of Food Investigation", that this publication should be continued The Board endorsed this recommendation and decided that the "Index" should cover the whole of the field which lies between the production of foodstuffs on one hand, and nutrition on the other hand, that it should be brought up to date as quickly as possible and should be published quarterly instead of half-yearly. In pursuance of this decision, the "Index" to the literature published in 1937 has now been issued, as vol. 9, Nos. 1–4. It is hoped to complete shortly vol. 7, No. 2 and vol 8, which will deal with the literature published during 1935 and 1936.

From time to time, the Board is asked whether food that has been stored by modern methods, such as cold storage gas storage or canning, is as nutritious as fresh food The question was put to the Medical Research Council who replied that in the present state of knowledge it is impossible to state categorically whether or not stored foods are as nutritious as fresh foods Nor is it feasible to undertake research with the view of answering that question directly since many years of intensive work on large groups of human beings would be necessary Even then there would be little prospect of arriving at a definite decision for with further knowledge of the effects of dietary factors on nutritional processes it would be found necessary to reconsider the results of the early years studies in the light of fresh evidence Nevertheless useful information can be obtained by comparing the chemical composition of stored foods with that of fresh foods and the general conclusion can be accepted that relatively little loss of known constituents occurs in foods stored by modern methods Moreover experiments on animals have shown that satisfactory nutrition can be maintained on diets composed solely of stored foods In fact food of good initial quality stored by the best modern methods is likely to be superior to similar food that though still technically fresh is in reality stale Vitamin C and to a less extent vitamin B_1 however are liable to be destroyed by heating

---

* Report of the Food Investigation Board for the year 1937, (Department of Scientific and Industrial Research) Pp 260+v (London H.M Stationery Office, 1938) 4s net.

The report of the Director of Food Investigation is divided as usual into sections dealing with the different foodstuffs and the engineering problems of food storage Two considerable pieces of work were undertaken for the Herring Industry Board the first dealt with the quality of kippers in relation to the quality of the fresh herrings from which they are made and the second with the freezing and cold storage of herrings The development of rancidity in the fat of herrings during cold storage is due to the action of certain enzymes which are activated by common salt Herrings frozen in brine need careful washing and glazing before storage the possibility of satisfactory freezing in air is being explored

Storage in ice will keep fish fresh for 10 12 days a period which covers some two thirds of the trips made by British trawlers Freezing in brine at −20° C with storage at the same temperature or at −30° C will keep white fish fresh for at least six months lemon soles have been kept in a palatable condition for as long as two years The fishing industry is now seriously considering the commercial possibilities of brine freezing and cold storage It must however be emphasized that the fish should be absolutely fresh when frozen it is of interest, therefore to note that a simple chemical test for freshness, based on the estimation of volatile organic bases appears promising According to the report the dimethylamine content of the fish follows the bacterial curve very closely during spoilage although the absolute amount present is much less than that of the triamine and ammonia (See also NATURE Dec 17 p 1078)

The increase in the hydrogen ion concentration which is essential to the proper keeping of the flesh of animals can only be ensured if an ample reserve of glycogen is present in the muscles at the moment of death The practice of resting animals for at least twenty four hours before slaughter is essential it is also advisable to give a ration of easily absorbed food such as cane sugar or glucose rather than to withhold food completely during this period Struggling on the slaughtering floor should also be reduced to a minimum estimations of lactic acid in the blood of slaughtered animals which have struggled show that an appreciable loss of acid may take place from glycogenolysis in the muscles the acid in the blood will not contribute to the rise in muscle hydrogen ion concentration

About two fifths of the report is devoted to the storage of fruit and vegetables The study of the respiration of the apple has brought to light a new fact of practical importance It appears that in the stage before the attainment of full maturity at which the fruit is often gathered namely just before the onset of the climacteric rise in respiration apples exhibit on exposure to concentrations of carbon dioxide up to 15 per cent a temporary increase in activity which may amount to as much as 100 per cent Hence the possibility of carbon dioxide accumulating to dangerous levels is greater in the period immediately after the fruit has been put into store especially if warm and respiring rapidly than had hitherto been thought possible

Experiments have been carried out on the cooling and storage of fresh strawberries for short periods A temperature of 38° F was satisfactory for 2 3 days storage but 32° F gave more control over fungal rotting and would probably be necessary for longer storage The rate of cooling affected the rate of subsequent deterioration With slow air speeds and a high relative humidity, no perceptible damage occurred in fruit cooled with air at either 23° or 28° F provided the fruit was not allowed to freeze A preliminary experiment on gas storage showed that the growth of fungal rots could be retarded without damage to the fruit by an atmosphere consisting of 10 per cent carbon dioxide 10 per cent oxygen and 80 per cent nitrogen

Other matters which are dealt with in the report are the storage of broccoli the preservation of pears and asparagus by freezing the effect of various methods of manuring the storage properties of apples, the storage of hothouse grapes and the ripening of imported pears and plums

The Nile Flood

By Dr. H. E. Hurst, C.M.G.

THE Nile flood of 1938 has been exceptionally high, and if we consider the Nile at Aswan, it was the highest since that of 1898 or perhaps 1892. Thanks to the protective measures carried out by the Ministry of Public Works, the water was passed through the whole length of Egypt to the sea (1,500 kilometres) without serious damage. Damage was limited to the loss of crops on islands and low lands lying inside the river banks and to infiltration, and this occurs in all years when the flood is fairly high Among the protective measures was the use of the Aswan Reservoir to prevent the river-level passing the danger point, whereby the peak was lowered by about twenty centimetres, and the level of the river reduced during about twenty days.

The flood is produced by rainfall (not snow) on the Abyssinian Plateau, which causes the Blue Nile, Atbara and their tributaries to rise regularly each year beginning usually in May or June and reaching their maximum in August or September. The White Nile contributes, but its variation is much less than that of the Abyssinian tributaries, and it does not reach its maximum until some weeks after the peak on the Main Nile is past. This year the maximum discharge on the Blue Nile was about 730 millions of cubic metres per day on September 2 and on the River Atbara 310 millions of cubic metres per day on August 23, while the maximum on the Main Nile at Wadi Halfa was about 1,020 millions of cubic metres per day and occurred on August 31.

There is no doubt that the present flood is the highest for forty years, but an exact comparison with the high floods of last century is not easy. Previous to the present century there were few measurements of discharge and these were always made with floats, so that we cannot compare directly quantities of water which are the real measures of floods. Current meters were introduced by Sir Henry Lyons at the beginning of the present century. There are, however, records of the level on gauges which have been read regularly for the last seventy years. The difficulty with these is that changes of river bed affect their readings, so that it happens that with two floods of nearly equal maximum height one may appear higher on the first gauge and the other on the second. There is reason to suppose that even the Aswan Gauge at the foot of the first Cataract has changed relatively to other gauges since the Dam was built at the beginning of this century. However, these variations are not as a rule large, and the gauges at some sites give a fair comparison of the heights and volumes of floods.

For more than thirty years there have been gauges on the tributaries of the Nile in the Sudan, the farthest south on the Blue Nile being at Roseires near the Abyssinian frontier, and thus warning of the rise of the river is obtained about ten days before its peak reaches Aswan. A similar warning is received from a gauge station on the Atbara, but the time interval is shorter.

The frequency distribution of floods is interesting. In addition to records of the level at Aswan which cover the last seventy years, there are records from the Roda Nilometer in Cairo which go back, although with large gaps, to A.D. 622, soon after the Arab conquest of Egypt. These records have not the precision of modern observations but are probably as reliable as present-day statistics about less well-defined phenomena such as health and social conditions, and they cover a very long period of the rise and fall of the Nile They have been analysed for periodicities by the late Prof. H. H. Turner, Mr. J. I. Craig and Dr. C. E P. Brooks, and periods varying from 2 to 240 years have been found The period of greatest amplitude so far is one found by Prof Turner of 240 years, with an amplitude of 15 cm for the maxima and 46 cm. for the minima.

RECORDS OF ASWAN GAUGE

Description	1869–1898		1899–1938	
	Height (metres)	Year	Height (metres)	Year
Maximum gauge reading of highest flood	94 15	1878	93 50 (Corrected for effect of reservoir)	1938
Maximum gauge reading of lowest flood	91·40	1877	90 11	1913
Mean flood maximum for period	93 26		92·46	
Number of years with maximum greater than 93·30 m	16		2	
Number of years with maximum less than 91 40 m.	0		2	

The analysis by Dr. Brooks does not extend to periods longer than 76 8 years, but he finds a number of periods of average amplitudes of the order of 10 cm. His best-defined periodicity is that of 76 8 years, with a mean amplitude of 17 cm. The average standard deviation of the flood-levels is 56 cm., which makes apparent the relative smallness of any periodic effects, which although of theoretical interest, are of no use to the forecaster. A glance at the records when plotted on a fairly large scale shows that there is no period which is directly evident to the eye, and that the principal features are the existence of fairly long terms of years when, on the whole, the floods have been high and others when floods have been low. This fact is well illustrated by the Aswan gauge records for the period 1869–1938. By dividing this period into two parts, 1869–1898 and 1899–1938, an example is afforded of a high term of 30 years followed by a low term of 40 years, with the results shown in the preceding table.

The most striking feature of this table is that in the thirty-year high term one year in two was higher than all but one of the succeeding forty-year low term. The important question, which however we cannot answer, is, are we now entering on a term of high floods ?

If flood heights are taken without regard to order, they give a frequency curve of normal form, but owing to the existence of high and low terms of years this frequency curve cannot be applied directly to give, for example, the chance of occurrence of a very high flood like that of 1878 in the next twenty years. Some work has recently been done on problems of this type which it is hoped to publish later

Obituary Notices

Prof. William McDougall, F.R.S.

WILLIAM McDOUGALL, whose death was recently announced, was partly Scottish, partly Saxon; he came partly of industrial and partly of agricultural stock; he was in part scientist and in part philosopher. One side of him was intensely interested in social movements and social activities; another was reserved, contemplative, and, to use his own word "arrogant". He was probably the most widely studied, the most universally known and appreciated of all contemporary psychologists. Yet to the end he regarded himself as an upholder of lost causes, a rebel against current conventions, a voice crying in the wilderness with but few to listen and to pay attention. In 1930, he wrote a brief, charming and frank autobiography ("History of Psychology in Autobiography", edited by Carl Murchison, Clark University Press. Vol. 1, pp. 191–223), and there, if anywhere, the paradoxes of his life and work are clarified and interpreted.

McDougall's life was a varied one. After a private school and a year at Weimar he entered the University of Manchester, and though he was at first deeply attracted by geology, he graduated in 'general science'. In 1889, he won a scholarship at St. John's College, Cambridge. At that time physiology was developing rapidly in Cambridge, and soon McDougall decided to specialise in this direction and to qualify in medicine, not in order to practise, but to fit himself more fully for original research. He took his degree with the highest honours and went to St. Thomas's Hospital, where he worked in the Physiological Laboratory, then under the direction of C. S. Sherrington. His research, partly on muscle contraction and partly on psychophysical problems, brought him a fellowship at St. John's College, but soon after this, in 1899, he joined the Cambridge Expedition to the Torres Straits, where he collaborated with W. H. R. Rivers and C. S. Myers in a comparative experimental study of native sensory reactions. He paid an extended visit to Borneo and saw something of China, Java and India before he returned to Cambridge.

For a day or two McDougall was an elected tutor of St. John's. But suddenly he flung aside one of his principles—"that a man whose chosen business in life was to develop to the utmost his intellectual powers should not marry before forty, if at all"—and married. For some time he combined a honeymoon and science at Göttingen, where he worked with G. E. Müller. Although he was somewhat out of sympathy with Müller himself, it was here that he began his experimental work on colour vision which many still think to be the best work he ever did. Characteristically he opposed Helmholtz, Hering and all his contemporaries who approved of their views. He said that he returned to Thomas Young, but it was a return with many differences. It was probably this work more than anything else which later won him his fellowship of the Royal Society.

Back in England, he taught experimental psychology for a few years at University College, London, and continued his own research on vision, on attention, and on general psychophysical problems He also planned a book on social psychology.

In 1904, McDougall became Wilde reader in mental philosophy at Oxford, and he continued to hold this post until shortly after the Great War. He was, he says, happy enough with the Oxford people—he became in due course a fellow of Corpus Christi—but very restive and discontented with the Oxford atmosphere of those days. When the Great War came, he was for a short time a private in the French Army and for a longer time a major in the British. At the Netley Hospital he had charge of a great many nerve and 'shell shock' cases and became deeply interested in the psychological study of functional disorders of the central nervous system.

During the Oxford period he wrote his "Introduction to Social Psychology", "Body and Mind", "The Pagan Tribes of Borneo" (with Dr. Charles Hose), the small Home University text-book and finally "The Group Mind". The first of these books, he says, dropped like "a stone into a bottomless pit". If so, it has successfully bounced out again, exhausted some twenty-three large editions and vastly influenced very nearly everything that psychologists have written about the subject since.

After the War, McDougall was invited to succeed Münsterberg in the chair of psychology at Harvard. He went to the United States with high hopes, found there very many friends, but was plunged into intense public controversy which persisted to the end of his life. American behaviourism represented for him everything which he most heartily disliked. He attacked it vigorously. He continued his attacks long after the battle had, to all intents, been won. He published book after book, and the motive of them all was the same, to fight all types of 'mechanistic' explanation in every field of science and to do this in the interests of "the art and theory of the internal life of man".

Harvard did not hold him for long. In 1927, he accepted a new chair of psychology at Duke University, North Carolina, and there he remained, latterly with yearly visits to England, until his death. On the whole this suited him the best of all his many dwelling-places The less hurried, more patriarchal atmosphere fitted well with his temperament and helped his work. His philosophical and ethical interests, always strong, became ever more pronounced. As a psychologist his primary concern was to establish a wide teleological point of view, and in so far as his experimental interests persisted, they were confined to a general approval of work on telepathy, clairvoyance and the like, and to his well-known Lamarckian experiment.

McDougall began the Lamarckian work at Harvard and continued it at Duke. He considered the question at issue "the most important question yet formulated by the mind of man and clearly susceptible of solution by experimental procedure"; and he was firmly convinced that his own long-continued work with white rats had achieved a "clear-cut and indisputable proof of the reality of Lamarckian transmission".

A few months before his death McDougall published his last book, "The Riddle of Life". He had set out, an unwearied soldier, upon his old campaign against mechanistic explanation in Nature and in life. He had conducted it with brilliance and with vigour. He was in the grip of a painful and a fatal disease. Only a "marvellous operation" enabled him to complete the work. As he read the proofs of this book it seemed to him that possibly some of his criticisms of physical and biological men of science might appear to be harsh and unsympathetic. So, himself near to death, he paid a last tribute to scientific endeavour. "I am now more than ever sensible of the splendour and achievements of modern science, and grateful to those whose skill and labour and genius have made possible such great benefits as I have received from the hands of my colleagues". He desired only that science should discard all pontifical claims and remain humble and honest in its search for truth. For himself the beginnings of the ultimate truth had been found. He saw in all forms of behaviour "some large unity or community of Nature underlying the separate individual organisms". He believed that, within every society, from insects to man, he could discern a harmony of activities "secured by the direction of some intelligent purpose more comprehensive and powerful than that of any individual member". F. C. BARTLETT.

AN anthropological correspondent writes:

Prof. McDougall, with the late Dr. W. H. R. Rivers, was a pioneer in the application of the methods of scientific psychology to the study of peoples of backward culture in the field, when they were both members of the Cambridge Anthropological Expedition to the Torres Straits under the leadership of Dr A. C. Haddon One outcome of this early interest in primitive mentality was "The Pagan Tribes of Borneo", which Prof McDougall published in 1912 in collaboration with the late Dr (afterwards Sir) Charles Hose. This intimate and detailed study of peoples, who when first known to one of the authors were in the enjoyment of a simple culture barely touched by European influence, is still one of the most highly regarded of ethnological treatises belonging to the early part of this century. A further result of Prof. McDougall's early studies in social anthropology is to be seen in his bent towards the sociological implications of psychological studies, which is apparent throughout his published works, and is especially to be noted in the analyses of world problems, which he has produced in the years since the Great War.

Prof. Georges Urbain

THE death on November 5 of Prof. Georges Urbain, director of the Institut de Chimie, past-president of the French Chemical Society, removes a well-known figure from French scientific life.

Born in Paris on April 12, 1872, son of a professor of chemistry, he studied at the Paris School of Physics and Chemistry and carried out research work under Friedel, Schutzenberger and Jean Perrin, obtaining his doctor's degree for investigations on the rare earths.

After five years of industrial research with the Compagnie générale d'Électricité, Urbain returned to academic life, lecturing at the School of Physics and Chemistry and later at the Faculty of Sciences of the Sorbonne, where he became professor in 1908.

The name of Urbain will always be associated with our knowledge of the rare earths. He showed that a number of so-called pure elements belonging to that series were in fact mixtures of europium, gadolinium, terbium and dysprosium. On the other hand, from ytterbium he separated a new element, lutecium (atomic number 71) and forecast the existence of a further element of atomic number 72 (celtium) which was later identified by Hevesy (haforium.)

In pursuing the difficult investigations connected with the separation of the rare earth elements, Urbain showed great versatility in employing many physical and chemical methods, often necessitating prolonged and tedious work It is estimated that, together with Lacombe, he had carried out some 200,000 fractional crystallizations over a period of fifteen years.

Like preceding investigators, Urbain began by studying the absorption and emission spectra of the rare earths, then went on to the magnetic properties and the phosphorescence in cathode tubes, discovering the law of optimum phosphorescence of binary systems. He also carried out many accurate atomic weight determinations.

In addition to his work on the rare earths, Urbain will be remembered for his contribution to the study of complex inorganic salts, which he considered to form a link between inorganic and organic compounds.

During his career, Urbain filled many important posts. He lectured at the École Centrale and presided over the Experimental Section of the École des Hautes Études. In the Great War he directed the Chemical and Technical Section of the Artillery.

These numerous activities none the less left Urbain time for artistic recreations. Those who attended the banquet in his honour given at the Maison de la Chimie last June were privileged to hear several of his original musical productions

---

WE regret to announce the following deaths .

Prof Edwin H. Hall, emeritus professor of physics in Harvard University, on November 20, aged eighty-three years

Prof. J Šplíchal, professor of inorganic and analytical chemistry in the School of Mines, Příbram, Czechoslovakia, who had only recently completed a lengthy study of the thermal decomposition of the carbonates of calcium, magnesium, iron and manganese, on December 8, aged fifty-three years

---

News and Views

Society for the Protection of Science and Learning

PERHAPS there is no finer testimony to the work undertaken by the Society for the Protection of Science and Learning, the report for 1938 of which was referred to in NATURE of December 17 (p. 1051) than the extent to which it has received the active support during the whole of its five years existence of the university staffs in Great Britain. Not only have individuals and committees in the majority of academic centres lent ready assistance to their exiled colleagues from abroad in the way of advice and vigilance for new openings for them, but also they have contributed financially more than £10,000 towards the funds of the organization which seeks to aid academic refugees. The Society itself has arranged a week of meetings early next term to take place in the great majority of British academic centres, with the view of spreading information concerning the plight and prospects of academic refugees Among those who have agreed to take part in these meetings are included · the Home Secretary, the Archbishop of York, Viscount Samuel, the Marquess of Reading, Sir William Bragg, Sir Henry Dale, Sir Richard Gregory, Sir John Hope Simpson, Sir Norman Angell, Sir Allen Mawer, Sir Bernard Pares, the Hon. Harold Nicolson, Mr. Philip Guedalla, Mr. Walter Adams, Prof. Gilbert Murray, Prof. Winifred Cullis, Prof. John Macmurray, Prof. P. M. S. Blackett, Prof. Lancelot Hogben, Prof. F. A. E. Crew, Miss Rebecca West and the Hon. V. Sackville-West. The Royal Society is giving a special reception to the academic exiles and those who have been working in their interests, in collaboration with the British Academy, on February 7 ; and on February 10 the evening discourse at the Royal Institution is to be given by Prof. Max Born, one of the most distinguished of the refugee men of science.

The Chemical Society

AT a meeting of the Chemical Society held at the Royal Institution on December 15, it was stated that Prof. Robert Robinson, Waynflete professor of chemistry in the University of Oxford, has accepted nomination to the office of president for the period 1939–41, which includes the centenary celebrations of the Society to be held in April 1941. The Longstaff Medal for 1939 has been awarded to Prof. I. M. Heilbron, for his outstanding contributions to the science of chemistry in the field of natural products, especially vitamin A and related natural pigments, the anti-rachitic vitamin D and its precursors, and the constituents of the fish liver oils and of natural resins of the triterpene group. Prof. Heilbron was lecturer in organic chemistry in the Royal Technical College, Glasgow, from 1909 until 1914, and in 1919 became professor of organic chemistry there. In 1920, he proceeded to the University of Liverpool as professor of organic chemistry; in 1933 he held the chair of organic chemistry in the University of Manchester. In 1938, he was appointed professor of organic chemistry at Imperial College, London.

AT the meeting of the Harrison Memorial Prize Selection Committee, consisting of the presidents of the Chemical Society, the Institute of Chemistry, the Society of Chemical Industry, and the Pharmaceutical Society, held on December 14, it was decided that the Harrison Memorial Prize for 1938 should be awarded to Mr. Alexander King. Mr. King received his chemical training at the Imperial College, South Kensington. From 1930 until 1931, he worked in the Physical Chemistry Institute of the University of Munich under Prof. K. Fajans, and from 1931 to the present date has held the post of assistant lecturer at Imperial College. His original investigations on adsorption and on emulsions and other colloid topics form notable contributions to our knowledge of physical chemistry. After a brief statement regarding the establishment of the Faraday lectureship, the president (Prof. F. C. Donnan) introduced Dr. Irving Langmuir, who then delivered the seventeenth Faraday Lecture entitled "Monolayers on Solids". At the conclusion of the lecture he presented the Faraday Medal to Dr. Langmuir.

Life-size Model of a Blue Whale

A MODEL of a 93-ft. Blue whale has just been completed in the Whale Hall of the British Museum (Natural History). It is constructed of plaster of Paris and cement on a wood and wire-netting framework and weighs between six and seven tons The proportions and colour are based on photographs and written descriptions and on very numerous measurements of actual specimens. Features of interest in the model are: the great size of the head, which is nearly a fifth of the total body length; the eye just behind the angle of the mouth, and the very small ear opening a little distance behind the eye; the tapering beautifully stream-lined flippers, and the enormous tail flukes some eighteen feet from tip to tip. The numerous grooves covering the throat and chest are a typical feature of the family Balænopteridæ to which this species belongs. The Blue whale, which grows to 100 ft., is the largest of all living animals and, so far as is known, the largest that has ever existed. At birth it is more than 24 ft. in length, and by its third year of life when it becomes sexually mature it is 74–77 ft. long. Its distribution is world wide, but at the present time the only remaining important area of concentration is in the Antarctic. There it is being hunted by the whalers for the oil obtained from blubber and flesh. During the 1936–37 antarctic whaling season, out of a total of 32,821 whales slaughtered, 14,183 were Blue whales

A Kentish Iron Age Hill-Fort

THE hill-fort at Oldbury, near Ightham, Kent, the excavation of which was described by Mr. J. B. Ward before the Society of Antiquaries of London on December 15, is the largest hill-fort of iron age date in Britain. Its ramparts are some two miles in circumference and enclose a space of 120 acres. Originally, it would appear from the evidence of sections cut in the ramparts, the erection was a place of refuge rather than a permanent settlement. This was at the very beginning of the first century A.D.; but later the gate facing the North Downs was elaborately refortified with stone-revetted fighting platform and outworks. The associated pottery shows that this refortification was carried out in A.D. 43 at the time of the Claudian invasion. Although Oldbury lay off the line of march of the Claudian armies proceeding from East Kent, where they landed, to Colchester, the evidence of the burning of the gates and quantities of sling stones suggest that it was sacked then or soon after. The camp was not again occupied. No Belgic pottery was found in the original fortification, but only in the later works. From this Mr. Ward infers that the original fortifications were erected by another people who had established themselves in the Wealden areas of Kent, Surrey and Sussex, working the local supplies of iron, and that its original purpose must have been to serve as a protection against the inroads of the Belgic tribes, whose headquarters lay north of the Thames The occurrence of Belgic pottery in the later fortifications suggests that by that time the Belgic people had taken possession of the fort.

Mesolithic Dwellings at Farnham, Surrey

EXHIBITS illustrating the culture of the inhabitants of mesolithic pit-dwellings at Farnham, Surrey, are now on view in the Prehistoric Galleries of the British Museum (Bloomsbury). These dwellings, on a site which is the only one of its kind as yet found in Britain, have been excavated by Dr and Mrs Grahame Clark. The results of the excavation, which has occupied two seasons, were described by Dr. Clark at a recent meeting of the Prehistoric Society The site of the settlement, which is the property of the Farnham Urban District Council, consists of a number of irregularly shaped pits, three feet deep in places, which have been scraped out of the gravel of the old Blackwater River. These pits represent the chief habitations of a mesolithic people, who probably spent their summers hunting on the Lower Greensand, when they lived in temporary shelters. Four huts have been excavated. In one pit there was a hearth and near another there were signs of a post, which probably had supported some light framework arranged tent-wise. Generally, however, the roofing seems to have been of the nature of a lean-to. Large numbers of microlithic implements were discovered, with flint axes, scrapers and waste flint cores and flakes. Altogether, between forty and fifty thousand worked flints have been discovered, and fifteen thousand flints cracked by fire have been found. These houses are, as stated, the first of their kind to be found in Britain; and they probably represent the first type of habitation in use in Britain other than the cave. They are considered to date from about 3000 B.C., and support the contention that artificially constructed dwellings are more ancient than has been thought. On the Continent, evidence is accumulating that mesolithic man was nomadic, inhabiting light shelters in the summer, and more or less permanent dwellings, usually of the pit-dwelling type, in the winter. The exhibits now shown in the British Museum are drawn from two of the dwellings excavated, and include a large and representative selection of the implements found

Accessions to the British Museum (Bloomsbury)

INTERESTING additions to the collections of British antiquities of the British Museum (Bloomsbury) were announced at the December meeting of the Trustees. Among these the most important is an iron sword of the second century B.C., with its bronze scabbard mount, which has been lent for temporary exhibition by the Duke of Northumberland. It was found in the River Witham below Lincoln in 1826, probably at the same time as the famous bronze shield of the iron age, which, with its characteristic Celtic ornament combining the use of metal and enamel, has long been one of the Museum's most striking exhibits among British antiquities. The decoration of the scabbard mount is an example of the earliest Celtic art of Britain, and shows the La Tène curvilinear style of ornamentation in the form in which it reached Britain Other accessions, also of great interest, come from a round barrow at Riffley Wood, near King's Lynn, which has been excavated by Mr. I. J. Thatcher and Mr. P. L. K. Schwabe. Among these are a segmented bead and a ring pendant of bluish-green faience, which were associated with nine or ten cremated urn burials of the Middle Bronze Age found on top of the mound. They belong to a class of ornament which has been found in bronze age burials in Britain and on the Continent; and they agree in all respects with examples found at Tell el-Amarna in Egypt, dating from about 1400 B.C. The grave pit of the mound below the level at which the urn burials were found, contained no remains; but the whole of the surface-level below the barrow was covered with pottery fragments, representing hundreds of vessels. These sherds were of beaker pottery of the Early Bronze Age, of the approximate dating of 1800 B.C It seems clear that this was not a habitation site, and the sherds are thought to be either the debris of the floor of the dead man's hut, which was brought here entire, or, perhaps more probably, the result of a ritual, which involved the scattering of a large number of potsherds.

The Iron Industry in South Yorkshire

BEFORE the introduction of mild steel about sixty years ago, engineers had to rely on wrought iron made by the puddling process introduced by Henry Cort in 1783. Among the various brands of wrought iron none was superior to those made in Yorkshire. But long before Cort's time iron was made in Yorkshire, and in a paper entitled "The South Yorkshire Iron Industry 1698–1759", read to the Newcomen Society on December 14, Dr. A. Raistrick gave an account of the operations carried out in the Sheffield–Leeds–Huddersfield area about two hundred years ago. The source of his information was manuscripts discovered a few years ago, and now preserved by the Bradford City Museums and Library Committee, relating to the activities of the various branches of the Spencer family, all Quakers. The documents give accounts of 10 furnaces, 14 forges and 5 slitting mills, and though much of the information relates to the business side of the industry, they embody a considerable amount of technical information about the mining of the iron ore, the construction and working of the furnaces and forges and the production of charcoal. The main group of furnaces was on the outcrop of the Tankersley Ironstone and near streams which were used for driving water-wheels for working the bellows. As in Sussex, a determining factor of the industry was the supply of charcoal, and it was rarely possible for a furnace to be worked for more than half the year. The manuscripts, as Dr. Raistrick said, put a new complexion on the story of the iron industry in the area.

British Coal Utilisation Research Association

ON December 14, the British Coal Utilisation Research Association held its first ordinary general meeting under the presidency of Sir Evan Williams. It was founded in April last, having incorporated the Research Department of the Combustion Appliance Makers Association (Solid Fuel) and with a membership covering all sections of the industries of coal and its appliance manufacturers. Its income from these sources and Government grant is guaranteed at £29,000 for five years. Premises near West Brompton Station have been secured and are being adapted to the purposes of an experimental station. It was stated that fruitful work has already been done in both the domestic and the industrial sections In the former this has been concerned with the open fire, and the use of natural smokeless fuels and smoke reduction. In this connexion it is claimed that success has been achieved in the design of solid fuel cookers to replace in railway restaurant cars those fired with oil gas On the industrial side, the supply and use of solid fuel for small industry, pulverized fuel, and industrial temperature measurement have engaged attention. A special committee has been set up to study the question of producer gas transport and supplement the work already in progress at the Fuel Research Station It has long been a matter of reproach against the coal industry that it has shown complete indifference to the rational and efficient utilization of its commercial product The launching of this Association will remove this reproach, and, as the president said, it will be "the missing member of a team which will work in harmony to bring about a more perfect knowledge of the properties of coal measures and advances in their fuller and better utilization".

Blind Landing System for Royal Air Force Equipment

THE Air Ministry has announced its intention to equip all R.A.F. bombers and reconnaissance aircraft with the Lorenz blind approach system. If experiments during this winter prove this to be successful, the fighter class of aircraft will then also be so equipped. This follows the announcement that forty R.A F. aerodromes would have the radio transmitting apparatus for this system installed, as mentioned in NATURE of November 26 The apparatus to be carried in each machine weighs 50 lb. and costs about £200. Its manipulation demands a certain technique, and pilots need considerable practice before being able to use it in addition to the other movements and observations that are incidental to the operation of landing a modern high-speed aeroplane. A special 'Link' trainer is used for practice in the use of the Lorenz system, upon which approaches and landings can be simulated without leaving the ground. These are to be provided at R.A.F. flying schools, in addition to which each service station will carry one. The training of the personnel will be undertaken by special instructors, who will have already attended courses at the Central Flying School at Upavon, Wilts.

Wedgwood's Portrait Medallions of Men of Science

IN his Friday evening discourse before the Royal Institution on December 16, Dr. John Thomas spoke on "Josiah Wedgwood and his Portraits of Eighteenth Century Men of Science". The great success of three fellows of the Royal Society—Josiah Wedgwood and his two friends Matthew Boulton and James Watt—as industrialists was discussed The successful production of artistic pottery at Etruria and of steam engines at Soho Factory, was only possible because of the persistent application of scientific principles. These 'philosophic' fellow-manufacturers endeavoured to satisfy this craving for scientific knowledge by attaching themselves to (*a*) the Lunar Society in the Midlands and (*b*) the Royal Society of London. Josiah Wedgwood, because of the artistic character of his jasper portrait medallions in the days before photography, established himself practically as the 'official' portrait producer of learned societies. Proof of this is the assembly of more than one hundred portrait medallions in Dr. Thomas's collection. Wedgwood handed the torch of science to his descendants, among whom was the illustrious Charles Darwin, his grandson, of whom Dr. Thomas exhibited a fine plaque by Wedgwood. Thus we, who live in the twentieth century, owe a great debt of gratitude to the 'prince of potters', not only for his scientific outlook, but also for the light which he has shed on his scientific contemporaries, through his inimitable portrait medallions.

Earthquake in Spain

AN earthquake was experienced in Spain on December 13, shaking the whole province of Valencia. The shock, which lasted three seconds, caused some apprehension and damaged buildings, but no casualties are reported. The district concerned is to some extent seismically active, as it borders the well-established Mediterranean region of earthquake activity, though it is not so densely populated with epicentres as is the region of Andalusia and Granada to the south of it. No really great earthquake has been experienced nearer to this region than Lisbon, 475 miles distant. It was from the Lisbon epicentre that the three shocks and several aftershocks occurred on and after November 1, 1755, at 9 h. 40 m. local time. The first lasted seven minutes, destroyed Lisbon and caused remarkable sea-waves in such distant regions as Scotland and Sweden. The second at 10 h. engulfed the Cays Depreda with the people on it and the vessels near it so that none of them were seen again, and altogether upwards of fifty thousand people lost their lives on that occasion.

New Merseyside Nature Society

FOLLOWING an inaugural field-meeting at Freshfield dunes and shore on December 11, a new nature study society for south-west Lancashire and Wirral was launched, as the Merseyside Branch of the British Empire Naturalists' Association, when the following officials were elected for 1939: *Hon. President*, J. W. Nixon (who is the Ribble Valley representative of the B.E.N.A. and honorary secretary of the Blackburn Naturalists' Field Club); *Chairman*, J. C. Miller, of the University of Liverpool; *Hon. Organising Secretary*, Eric Hardy. It was announced that the new Merseyside Naturalists' Association would cover the area between the Ribble and the Dee on a much more modern and active method of general field nature study than was at present available in the area, although it was in no way antagonistic to some ten older natural history societies in the district. Mr. Hardy stated that the Society had been formed by about fifty naturalists and nature-lovers who had given their signatures to the desire for introducing the B.E.N.A. work to Merseyside. It was agreed that in 1939 they report on their area for the national bird survey being carried out by the scientific committee of the British Trust for Ornithology, and for the selected list of trees and insects chosen for national observation by the B E.N.A. headquarters. Arrangements had been made for combination with the branches of the B.E.N.A. for Manchester and West Lancashire (Lytham)

The Parliamentary Science Committee

THE fifth annual meeting of the Parliamentary Science Committee was held at the House of Commons on December 13, under the presidency of Prof J. Graham Kerr. The honorary secretary's report disclosed that the Committee's constituent bodies now number twenty-six, five of which have become affiliated during the past twelve months. Three peers and fourteen Members of Parliament are now associated with the executive, with the result that the Parliamentary activities of the Committee have greatly extended. Interventions in debate on the initiative of the Committee were frequent last session; more than thirty questions were asked in the House of Commons on scientific and technical matters; and during the current session it is hoped that members will be fortunate in the ballot for private members' motions. The Committee has been associated with Parliamentary action on the Thames barrage and the removal of the oil tanker limits on the Thames Negotiations are on foot to establish complete liaison with the new Division for the Social and International Relations of Science of the British Association Two lectures were arranged during the last session at the House of Commons for Members of Parliament. The following were elected officers for 1939 *President*, the Right Hon the Earl of Dudley, *Vice-President*, Sir Arnold Wilson, M.P.; *Chairman*, Mr. S. F. Markham, M.P.; *Vice-Chairman*, Prof B. W. Holman; *Deputy-Chairman*, Mr. Alan E. L Chorlton, M P.; and *Hon. Secretary and Treasurer*, Mr. H. W. J. Stone.

The Cultural Influence of the Cinema

THE League of Nations Advisory Committee on Social Questions has issued a report, based on information collected from the Governments of forty-six countries and from other sources, on "The Recreational Cinema and the Young" (London: Allen and Unwin. Pp. 32. Price 9*d*.). It discusses the frequency of the attendance of young people at cinema theatres, the effects of attendance, juvenile taste in films, protection from unsuitable films, teaching of film appreciation, special performances and special films for juveniles. Of outstanding interest under the two last-mentioned headings are accounts of certain activities of the Governments of the U.S.S.R. Their "Children's Cinemas" are, it is said, equipped on broadly conceived lines as recreational centres. In addition to the theatre itself, they include a large hall for games and musical programmes, a library and reading room, a room for quiet table games, a refreshment counter, and a sort of cinema museum in which are displayed exhibits illustrating the history and technique of cinema production with sets of photographs of the best films and leading cinema personalities. Children are encouraged to amuse themselves, before the performance begins, in the various rooms, especially the large hall, where the programme usually is such as to prepare them for understanding the film about to be shown

APART from the technical staff of these Children's Cinemas, a special staff of teachers is employed in these houses. A special section of the Central Department for Industrial Cinematography employs a regular staff for the making of films for children, the subjects including travel and exploration, animal life, children of the U.S.S.R. and other countries, lives of remarkable persons and works of popular children's authors, among whom are mentioned Mark Twain, Jules Verne, Swift, Kipling and Pushkin. For the guidance of makers of such films certain basic principles have been prescribed, such as: "Any attempt to address children otherwise than in the real language of art, to 'talk down' to the child's intellectual level—i e., any conscious or deliberate simplification—makes the juvenile film stereotyped and false. It should be simple with the simplicity of a real work of art, but not simplified".

Technical Progress and Unemployment

AN Advisory Committee on Management (International Labour Organization) at its meeting on May 2 and 3 studied the practical methods which industrial undertakings could adopt to alleviate the immediate social consequences of the elimination of surplus works or technical equipment and of the rapid and extensive mechanization of production (Geneva: International Labour Organization). The Committee drew up a list of measures which might be taken by organizations obliged to reduce their staff in consequence of progressive mechanization or other industrial changes. These measures are classified into five groups according to whether they are preliminary and designed to postpone or minimize or avoid dismissals as, for example, by reduction of hours or transfer of workers to other services; those intended to systematize inevitable dismissals, taking account of all psychological and moral issues involved; those intended to help workers who are dismissed; measures of adjustment among the remaining staff, and general measures involving co-operation with staff representatives, other undertakings and official or private organizations.

IN regard to the measures for dealing with actual dismissals, the Committee stresses the importance of selecting workers for dismissal on the basis of objective criteria, the information of staff in advance and the careful spreading of dismissals over a period. The Committee also considered a report prepared by the International Labour Office on the use of office machinery and its influence on conditions of work for staff. Various technical means of mitigating the physiological and psychological consequences of the mechanization of office work were suggested by the Committee, which in regard to the general effects, expressed the opinion that a reduction of hours of work in offices would assist in reducing those drawbacks. The Committee also holds that to counteract the occupational consequences of the use of machines, the social guarantees recognized as due to the industrial worker should be granted equally to office employees, especially by a general extension of social legislation and of the system of collective agreements.

The Rockefeller Foundation

THE Rockefeller Foundation in 1937 distributed a total of more than 9,500,000 dollars Fifty-five per cent of the grants were for work in the United States, and among the largest appropriations and authorizations of the year were 420,000 dollars to the China Medical Board for the maintenance of the Peiping Union Medical College; 360,000 dollars to Harvard University for research in industrial hazards; 300,000 dollars to the Yale University School of Medicine for the Department of Psychiatry, 300,000 dollars to the California Institute of Technology for the development of organic chemistry; 275,000 dollars to the National Research Council for research in problems of sex and in biophysics; 250,000 dollars for the general research fund of the Yale University School of Medicine; 240,000 dollars to the Royal Institute of International Affairs for research in international problems; 156,000 dollars for teaching and research in psychiatry at the Harvard Medical School and Massachusetts General Hospital; 150,000 dollars to the National Institute of Economic and Social Research for basic economic research, and 100,000 dollars to the International Institute of Intellectual Co-operation for research in connexion with the International Studies Conference. The annual report of the Foundation includes the president's review with the detailed reports of the secretary, the treasurer and the directors of the International Health Division, the Medical Sciences, the Natural Sciences, the Social Sciences and the Humanities and the vice-president in charge of the programme in China.

IN the natural sciences, the Foundation has given its major support to experimental biology, including research on hormones, nutrition, and enzyme chemistry, while assistance given to organic chemistry has been largely prompted by a desire to develop work on its biological aspects with the view of forwarding the progress of medicine itself in the United States. The president's remarks on the social sciences are of special interest at the moment. Emphasizing the importance of scientific work in this field, he suggests that in it lie the possibilities of ultimate social intelligence. Social progress more and more requires minds trained to function scientifically on social problems, as well as improved facilities for observing, recording and interpreting social phenomena and public recognition of the importance of accessions of knowledge in this field. The appropriations of the Foundation in this field in 1937 were largely for the promotion of research in social security, international relations, and public administration. It is satisfactory to note that although the normal development of the work in China has been rudely interrupted, no project has been discontinued, although six out of the eight major projects have been forced to leave the areas in which their work was being done. Reference has already been made in these columns to the president's comments on the barriers to the work of the Foundation which have been encountered through restrictions on intellectual freedom in certain countries (see Nature May 21, p 939).

The Gas Engine Afloat

In a paper on 'Marine Engineering Problems of To-day' read to the International Conference of Naval Architects and Marine Engineers in June of this year, Mr Sterry B Freeman suggests that the time is now ripe for a reconsideration of the gas engine for ship propulsion. On October 11, Mr J F Gibbons read a paper at the Institution of Marine Engineers on "Gas Engines for Small Craft". The author considers only small vessels like tugs, colliers, coasters and trawlers, using gas producers of ordinary type and the power contemplated lying between 300 and 1,500 h p. Mr A E L Chorlton in 1913 outlined a proposal for a gas steam plant of 5,500 brake horse power suitable for driving a Channel passenger vessel, and took as an example the well known passenger steamer *La Marguerite*. The gas engines in this design were to be arranged athwartship and geared to the paddle shaft. They were assisted in manœuvring by uniflow steam cylinders, the steam being supplied by a waste heat boiler operating on the gas engine exhausts. In the early stages of development there was no competition by the oil engine, as it had not yet been developed. The ordinary type of marine steam reciprocating engine often operated more economically. In those days, the cost of coal was much less than it is now so there was less urge to reduce its consumption. The question now is very different. Apart from the national advantage of having fuel in the country that does not need to be imported, a great deal of experience has been gained in the design of small producers for use on road vehicles. In an article in *Engineering* of November 4, it is stated that if the use of gas engines and producers afloat, instead of being tentatively explored by individuals, had been persevered in by established engineering firms, with only a fraction of the financial backing that has been given to Diesel engines, there is little doubt that by now the technical problems would have been commercially solved.

Does the Mocking-Bird Mock?

The mocking-bird (*Mimus polyglottos*) repeats notes used by other birds, and one case at least has been recorded where it was able to do so by the time of its first winter plumage, that is, before it had had much experience in listening to other birds. A suggestion has been made, therefore, that long racial habit in mimicry may have impressed these notes upon the genetic complex of the species, so that the young individual inherited, rather than learned, the adopted song—an acquired character in fact. On the other hand, there is a possibility that the repetition of notes may be due to parallel ability and adventitious similarity rather than actual and individual mimicry. Another suggestion is made by Loye Miller (*The Condor*, 40, 216, 1938). He interprets the song as a sequence of *motifs*, each *motif* being commonly repeated from three to nine times (making a unit) before a new *motif* is adopted. An ordinary song employs from thirty five to fifty of such units. Now these *motifs* are largely original: rarely do 10 per cent of them resemble the notes of other species of birds, and the resemblances may be fortuitous or mimetic. But the fact that the notes of the California woodpecker or of the shrike are repeated only in places occupied by these birds, suggests some deliberate mimicry. Miller suggests that the mocking bird is not to be regarded as a plagiarist, but as an artist picking up a suitable stave wherever it may be found to weave into its own roundelay.

Improvement of Child Nutrition

An appeal has been circulated by the Children's Minimum Council, 72 Horseferry Road, S W 1, for the improvement of the nutrition of children, and to ensure that no child, by reason of the poverty of its parents, be deprived of at least the minimum of food and other requirements necessary for full health. The Council desires that free milk may be available for all school children, and also midday meals in all schools under local education authorities. Where the expenditure available for food is insufficient, it urges the provision of cheap milk for expectant and nursing mothers and children under school age, and free meals for older children. It is maintained that if the known deficiencies in the national dietary were made good, a revolutionary improvement in the public health would certainly follow. The Council needs an income of at least £1,000 a year for the continuance and expansion of its work, and subscriptions are invited for this purpose.

Journal of the Czech Astronomical Society

With a delay of only one month during the crushing events of last October, the next issue of *Říše Hvězd*, the monthly journal of the Czechoslovakian Astronomical Society, has been published under an editorial entitled Začínáme Znovu—"We start again". In this editorial, Dr Hubert Slouka calls upon all Czech astronomers to unite in working together for the creation of a well-equipped Government observatory, even if only a modest beginning can be made

The need for such an observatory is further intensified by the recent ceding to Hungary of the Astrophysical Observatory of Stara Dala. Astronomers and other men and women of science will unite in wishing a happy outcome to this gallant determination to start anew.

Publications of the Carnegie Institution of Washington

A **catalogue** of its publications has been issued by the Carnegie Institution of Washington giving a classified list of publications in various branches of science, international law and literature. Most of the books marked in the classified section as out of print are to be found in the libraries throughout the world which have been selected as depositories of the publications of the Institution. A list of these depositories will be sent on application, and a few copies of each publication are reserved for sale at prices which are less than the cost of printing. Price lists or classified lists may be obtained on request and special lists of reprints relating to the work of the Geophysical Laboratory, the Nutrition Laboratory, the Department of Terrestrial Magnetism and the Mount Wilson Observatory can also be obtained. The catalogue also includes an index of authors.

Bibliography of Seismology

We have just received vol. 12, No. 18 of this valuable work, and hope that collaborators in many other countries where seismological work is being done will soon come forward. The U.S.S.R., the Balkan States, and South America, to mention only three, and this time even Germany have no representative. It is pleasing to note that Italian papers are represented, and there is a very full list of American publications. It might be suggested that periodical publications of observatories throughout the world be noticed as, in addition to routine readings of seismograms, the more fortunate observatories find time to investigate shocks local to the station. There is a full list of seismological notes from Nature.

Mineralogical Society of America: Roebling Medal

Dr. Waldemar Theodore Schaller, chief mineralogist of the United States Geological Survey, an authority on rare and unusual minerals, has been awarded the Roebling Medal by the Mineralogical Society of America "for meritorious achievement in mineralogy and allied sciences". This Medal, awarded for the first time in 1937, was established in honour of the late Colonel Washington A. Roebling of Trenton, N.J., whose private collection in the field of mineralogy, now forming part of the display at the United States National Museum, contained some 16,000 specimens, many of them very rare, and was one of the most complete in the country. Colonel Roebling's interest in the growth of the Mineralogical Society led him to create an endowment fund to provide a wider scope in mineralogical publication. The medal commemorates his lifelong concern with mineralogy.

Announcements

The following elections to the Paris Academy of Sciences have been announced: Prof. W. J. de Haas, professor of physics in the University of Leyden, to be *correspondant* for the Section of Physics in succession to the late Dr. C.-E. Guillaume; I Holmgren to be *correspondant* for the Section of Medicine and Surgery in succession to the late Prof. I Pavlov; M Paul Wintrebert, professor of comparative anatomy and histology in the Sorbonne, to be a member of the Section of Anatomy and Zoology in succession to the late F. Mesnil.

Dr. Heinrich Ritter von Srbik, professor of history in the University of Vienna, has been nominated president of the Academy of Sciences of Vienna

The German Society for the Study of Colloidal Chemistry has awarded its grand annual Laura Leonard prize to Prof M. Samec of Ljoubljana for his work on the colloidal chemistry of starch.

Dr. Desidor Miskolezy, professor of psychiatry at Szeged, Dr Roman Adelheim, professor of pathological anatomy in the University of Latvia, Riga, and Prof. Charles Spearman, emeritus professor of psychology in the University of London, have been elected members of the German Academy of Natural Science at Halle

Dr H Morley Fletcher is representing the Royal College of Physicians of London at the opening of the Royal Australasian College of Physicians at Sydney He presented on its behalf to the new College an illuminated address and a replica of its silver wand or caduceus given by Caius in 1556.

At a meeting on October 28 of the international committee for instruction and action for the protection of a civilian community in war, which was set up at Luxembourg on July 4, sub-committees were formed to deal with propaganda, diplomacy, military matters, medical treatment, legal questions, civilian defence and protection of women. The next meeting of the international committee will be held at Luxembourg next January.

The Annual General Meeting of the Association of Women Science Teachers will be held in Bedford College for Women, Regent's Park, London, N W.1, on January 4–5. On January 4, Prof. Alan Ferguson will deliver a lecture entitled "Some Notes on Eighteenth Century Physics". On January 5, a discussion on "New Methods of Biology Teaching emphasizing Practical Problems with Living Organisms" will be opened by Mrs. Hatfield. Further information can be obtained from M. W. Sutton, 18c Christchurch Road, London, S.W.2.

Erratum.—In the article on "National Parks" in Nature of December 17, p. 1087, second paragraph, line 18, for "16,000 ft." read "1,600 ft."

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

Notes on points in some of this week's letters appear on p. 1123.

Correspondents are invited to attach similar summaries to their communications

Coherent Modified Scattering of Light

IT has been assumed hitherto that when light is diffused by the particles in a medium with frequencies different from that of the incident light, the radiations from the particles are necessarily incoherent with each other. The following considerations indicate that this need not always be the case, and indeed that coherence is possible and may play a very important part in the scattering of light with altered frequency.

Consider two neighbouring volume elements in a medium and assume that as a result of translatory or rotatory movements of the molecules contained in them, the optical properties of these volume elements vary with time. This variation may be analysed into its Fourier components and we may, for the moment, fix our attention on a component having the frequency ν^*. Under the influence of the incident monochromatic light of frequency ν, each of the volume elements will emit secondary radiations of frequency $\nu \pm \nu^*$. Since the incident light wave at the two volume elements has a definite relation of phase, the scattered radiations would also be partially or completely coherent, provided that the fluctuations of frequency ν^* in the optical properties of the two volume elements are either partly or completely correlated in phase. If such a correlation of phase exists, it must be considered in evaluating the intensity of the modified scattering which is the resultant of the effect of the different volume elements in the medium. It will be readily seen that in general, the resultant intensity would be different in different directions of observation.

If the frequency ν^* be small, the detection of the modulated frequencies, $\nu \pm \nu^*$, would require the use of an interferometer. A correlation of phase of the oscillations in the neighbouring volume elements would necessarily exist, if there are *stationary* waves in the medium covering a wide range of frequencies. In those directions where the phases of the scattered radiations are most nearly in agreement, we should expect the scattered light to show most strongly the modulated frequencies $\nu \pm \nu^*$. An explanation is thus forthcoming of the effects depending on the direction of observation, which have been observed in interferometric studies of light-scattering in fluids and solids.

The point of view here suggested has the merit of bringing the observed changes of frequency under the single general principle governing all such changes, namely, that the frequency of the scattered light is the sum or the difference of the frequency of the material particles and of the radiation frequency. It is thus more general than the well-known theory due to Brillouin,[1] which regards the observed displacements of frequency as Doppler effects arising from *progressive* sound waves in the medium. According to the concepts here outlined, the scattered light should in general exhibit a continuous spectrum with maxima of intensity depending upon the direction of observation rather than discrete frequencies as suggested by Brillouin's theory. The appearance of the component of unmodified frequency also receives an instantaneous explanation as due to the existence of local fluctuations of infinitely low frequencies in the medium. The new point of view also indicates that harmonics of the oscillation frequencies should be observable in favourable cases as frequency shifts in the scattered radiation.

A further application of the idea of coherence to the problem of light-scattering seems to arise in the case of those oscillations in crystals which are classified under the heading 'lattice frequencies'. It would seem difficult to explain the great intensity with which frequency shifts of this class appear in the light-scattering by crystals unless a coherence in phase of the oscillations of the neighbouring lattice units in the solid is assumed to exist. This idea, however, requires further examination, and we are putting it forward in this note with due reserve.

The Sub-Arctic Region as a Molluscan Habitat

THE Mollusca, as an ancient, widely distributed and relatively diversified group of animals, provide favourable material for biogeographical study. The freshwater and terrestrial Mollusca of the Sub-Arctic Region (which may be defined as the territory lying between the fiftieth parallel of north latitude and the Arctic Circle except in north-western Europe and western North America, where the boundaries lie farther north) are of special significance since in that region the effect of progressively more unfavourable conditions of life upon animal distribution can be observed upon a vast scale. The following note, which is based upon original observations[1,2,3,4], may therefore be of interest.

The presence of a relatively small number of species, many of which have a wide geographical range, and are to be found in large numbers of individuals, is the most characteristic feature of the molluscan fauna of the Sub-Arctic Region. Conditions of life for molluscs in this northern region are evidently so severe that the majority of the species which inhabit the southern part of Europe, Asia and North America are unable to survive in the sub-arctic sectors of those continents.

In some instances the molluscs which are found in the Sub-Arctic belong to 'archaic' groups which in former times occupied a more or less predominant position in the molluscan fauna of the world, but have now been superseded over the greater part of the earth's surface by more recently evolved and apparently better adapted forms. The super-family of land snails known as Orthurethra, which includes the families Vallonııdæ and Pupillidæ may serve as an example. This super-family is a group of primitive Basommatophora (Mollusca, Pulmonata) of which the existing members are the scattered descendants of an ancient snail fauna of the world. The few survivors of this group which are still found on the great continental land masses now occupy the poorer habitats and the less-favourable regions, such as the Sub-Arctic, into which many species belonging to the more recently evolved groups of snails have not followed them as yet.

It may be seen to be somewhat remarkable that although the hardy molluscs which are able to survive under sub-arctic conditions have had the ground to themselves, there has been little tendency for them to give rise to new species and varieties which are characteristic of different parts of the territory. Apart from a conceivable direct physical effect of low temperature upon the rate of evolutionary change, the explanation of the very limited degree of speciation in the Sub-Arctic may well lie in the geographical conditions, and particularly in the sameness of the environment over vast tracts in this region. Only a very few types of landscape are found in the Sub-Arctic[3], and in each of them conditions of climate, soil and vegetation are strikingly similar at widely separated points This must surely result in there being only a limited number of food chains available to the animal inhabitants of a given area. Under such conditions it seems to be reasonable to conclude that the opportunities for new species to establish themselves successfully are correspondingly limited as compared with other areas having a more diversified landscape.

There are certain exceptions to the general rule of sameness, and poverty so far as the number of species is concerned. The most notable of these exceptions are to be found in the freshwater families Lymnæidæ and Planorbidæ (Mollusca, Pulmonata), and in the fauna of Lake Baikal. The usual habitat of Lymnæidæ and Planorbidæ is in ponds and lakes. As a result of widespread glaciation within relatively recent times, ponds and lakes are common in many parts of the Sub-Arctic and even a casual examination reveals a wide range of different physical, chemical and biological conditions in them. So far as these particular molluscs are concerned, therefore, the opportunities for diverse modes of life (which probably form the basis of any successful attempt by new species to establish themselves) are quite considerable. The other outstanding exception is the molluscan fauna of Lake Baikal. This is a large body of fresh water situated in Eastern Siberia approximately midway between Calcutta and the mouth of the River Lena. The animal population of this lake is of a highly remarkable character. Approximately ninety per cent of the species of animals, the majority of the genera, and many of the larger groups are strictly confined to this one body of water. Moreover, the fauna is a rich one. The exact number of species of Mollusca which are present is not known[2,5], but it is believed to be large. The explanation of the presence of this highly peculiar and abundant fauna in Lake Baikal probably lies in the uninterrupted biological history of this body of water since Jurassic (?) times, and the great diversity of conditions met with in the Lake. In this latter connexion, the profound depth of the Lake (maximum 1,741 m.) is probably of some significance.

The impression gained from a study of the Sub-Arctic Mollusca, therefore, is that the general character of the fauna has been brought about to a considerable extent by geographical conditions and particularly by the types of habitat available. If there was once more a clear field in the region and comparable biological material found its way into the country, there appears to be a considerable likelihood that although the channels of development might be different, the resulting fauna would be of very much the same character as the one which exists in the region to-day.

Directed Hereditable Variations Conditioned by Euploid Chromosome Alterations in Higher Plants

IN studying a series of eupolyploid plants produced during the last few years[1] and especially those produced recently by colchicine and acenaphthene treatments[2,3,4,5] in Solanaceæ, Compositæ, Gramineæ, etc., I found that eupolyploid chromosome alterations condition a series of hereditary variations Most of them are directed; others are not. Directed hereditable variations in plants which show an increase with the euploid increase of the chromosomes are: (1) amount of nucleolar substances (number of nucleoli, size, or both); (2) volume of the nuclei; (3) amount of cytoplasm per cell; (4) volume of the cell; (5) breadth of the leaves; (6) thickness of the leaves and the weight of unit surface portions of the leaves; (7) size and weight of the ovules; (8) size and weight of the seeds or of the grains; (9) size and weight of the anthers; (10) breadth of the styles and stigmas; (11) breadth of the petals; (12) thickness of the petals; (13) length and breadth of all kinds of trichomes (on the leaves, stems, flowers and seeds); (14) number of the chloroplasts per cell; (15) amount of chlorophyll at unit leaf surface; (16) expression of the green colour of the leaves; (17) expression of the corolla colours, and (18) metabolic (photosynthesis) and katabolic (carbon dioxide) processes per unit leaf surface.

The length of the vegetation period (from planting of the seeds until the beginning of the flowering) increases in almost all plants with doubled chromosome numbers. Most of the latter plants are larger than their 'diploid' forms. This is especially true for plants with relatively small chromosome numbers. But there are also cases when chromosome duplication does not necessarily lead to an increase of the plant size. In a few cases polyploids are smaller than their original diploids (octoploid *Nicotiana Sanderæ*). The length of the flowers (corolla and calyx) and the breadth of the corolla behave in a similar way. All organs of the polyploid plants appear coarser.

The sizes of the fruits and capsules change in different ways. They are chiefly regulated by the number of the seeds. The number of the seeds, that is, the suppression of fertility in autopolyploids, depends greatly on the length of chromosomes and on the degree of polyploidy (chromosome number). Plants with longer chromosomes set much smaller percentages of seeds per capsule in respect to their original forms than plants with shorter chromosomes. When the plants have chromosomes approximately equal in length, those of them that have many more chromosomes (higher polyploidy) set less seeds per capsule. This is true for higher degree of polyploidy. It does not always hold for the members of the polyploid series with smaller chromosome numbers These regularities are of great evolutionary significance.

The contents of various chemical substances are altered in different directions as results of chromosome duplications.

Polyploids have not larger plastids. The latter show great autonomy in respect to the nucleus (chromosomes, genes).

Hereditary variations conditioned by euploid chromosome alterations are of great agricultural value, because we can predict, for most of them, the direction of changes after chromosome doubling. Contrary to this, all hereditary variations conditioned by gene mutations, and structural or aneuploid chromosome alterations, that we can induce at the present time, are not directed.

The realizations of the characters in polyploid plants compared with those of their 'diploids', as described above, are contrary to the mechanistic conception of the nature and behaviour of the organisms.

Genetics of Hybrid Sterility

IT is a remarkable fact that the disturbances connected with genic sterility in hybrids between species (or races) are paralleled within species by similar disturbances caused by single genes. For example, there is an analogy between the asynaptic mutations in several plants and genic asynapsis in hybrids and likewise between the polymitotic mutation in *Zea* and the spermatogenesis in *Drosophila pseudo-obscura* hybrids. Similarly, I have recently found a property analogous to the long-chromosome mutation in *Matthiola* in a grasshopper hybrid, the chromosomes of which also show a sort of 'stickiness' reminding one of the 'sticky' mutation in *Zea*[1]. Dobzhansky has several times directed attention to this parallelism[2], though he does not seem to think it has any deeper genetical significance. In my opinion, there is, however, a possibility of putting the two phenomena on a common basis.

Dobzhansky's admirable work on hybrids between *Drosophila pseudo-obscura A* and *B* has shown that at least eight sterility genes, spread out over the whole set of chromosomes, are present, all of them having like and cumulative effects. We may presumably take for granted that such series of sterility genes are at work in other cases of genic sterility in hybrids as well. Assume that these genes are of the same kind as the sterility genes known to act within species. But instead of having one recessive with a strong effect, we are concerned with a series of recessives with but slight effects. Assume further that they only become effective if a certain, not too small, minimum number is present in a homozygous state. Then, even a moderate mutation pressure will be able to infiltrate a cross-breeding population with mutated genes until the proportion of them at every locus concerned approaches or exceeds 50 per cent. The distribution of mutated loci in any gamete produced in the population, with random mating and absence of linkage, is given by the binomial expansion. Thus the number of mutated loci present in a gamete in a population of moderate size will vary within relatively narrow limits, being usually about half the number of sterility genes in the whole population. Since the mutated genes of two gametes constituting an individual will as a rule be at different loci, individuals homozygous for as many genes as to cause sterility will practically never arise (except on inbreeding) The accumulating evidence as to the occurrence of deleterious recessives in wild populations indeed makes it conceivable that such genes with very slight, but cumulative, effects are widely spread.

The species (or races) engaged in a cross will probably have developed their sterility genes during and after their isolation from each other. Different environments and pure chance will have led, for the most part, to different sets of sterility genes becoming established. At the same time a genetic system making the genes concerned recessive must have arisen (Fisher[3]); these systems, too, must be different, each acting on its own set of genes only.

Consequently, on crossing related species two sets of sterility genes would enter the hybrids. The specific recessive-making systems would break down (*cf.* Harland's work on *Gossypium* hybrids, reviewed by Dobzhansky[2]). The two series of sterility genes, now dominant or semi-dominant, would combine to give the same sterility effect as they would in a homozygous state in a non-hybrid individual.

Occurrence of Burbot in the Estuary of the River Severn

A SYSTEMATIC study has been made during the past year of the fish and invertebrates caught in the kypes or 'fixed engines' secured between tide marks in the upper regions of the Bristol Channel, between Avonmouth and Gloucester. During the spring of 1938, three specimens of the burbot, *Lota vulgaris*, were obtained. Two, measuring 9 cm. and 10·5 cm. long respectively, were caught during February in kypes at Oldbury, and the third, 11·5 cm., during March at Hallen, some eight miles nearer to the sea. These appear to be the first modern records of this fish in the West of England, although it is not uncommon in the rivers which flow into the

North Sea between Durham and East Anglia and is of general distribution in northern and eastern Europe.

It is possible, however, that this fish has been previously observed in the estuary of the Severn. Mr. L. H. Matthews has directed my attention to a list of fishes contained in John Smyth's "Berkeley Manuscripts" written at the end of the sixteenth century. This is a description of the Hundred of Berkeley in the County of Gloucester with an account of its inhabitants, and among the fish listed is the "Eele pout", one of the various English names of this interesting freshwater representative of the Gadidæ.

Effect of Organic Acids on Germination, Growth and Ascorbic Acid Content of Wheat Seedlings

Several observations made on dehydrogenase activity of various seeds have been described by Thunberg[1,2]. These investigations have directed attention to the fact that different seeds show different capacities for the utilization of dehydrogenase substrates.

In the experiments here sketched, an attempt has been made to follow the effect of various aliphatic organic acid substrates of dehydrogenase systems on the germination and growth of wheat seedlings, and also their effect on the ascorbic acid content of the germinated seeds.

The sterilized seeds, pure line Wilhelmina wheat from the National Institute of Agricultural Botany, Cambridge, were germinated on moist filter paper placed in sterilized Petri dishes. Each dish contained thirty seeds. The acids were dissolved in sterile twice distilled water and were stored on ice The technique of these experiments was similar to that already published by Havas[3]. Acids were used in two concentrations, namely, 5/1,000 and 1/10,000, this choice being based upon experience obtained in earlier experiments of a similar nature[4]. The duration of the experiments was twelve days, by which time the food reserves of the seeds were exhausted. The results obtained involved examination of some 1,600 seedlings.

The observations have shown that different acids of the same concentration exert entirely different effects on the growth and germination of the wheat seedlings. At a concentration of 5/1,000, an inhibiting action was observed in each case. Despite the fact that such hydrogen ion concentrations (pH 3·0–4·0) are not optimum for the germination of wheat seedlings, this inhibiting action cannot be due entirely to the acid reaction of the solutions, since if this were the case one would expect that each acid would act similarly. This, however, is not the case. Such acids as citric, lactic and succinic, which are the substrates of the most important dehydrogenase systems, do not inhibit germination or growth completely even at a concentration of 5/1,000. The inhibition is only of the order of 60–70 per cent at a concentration of 5/1,000, whilst fumaric, malonic, oxalic and pyruvic acids exert a completely inhibitory effect on germination at this concentration. This action is all the more interesting because, according to Fodor's investigations[5], wheat-germ extract produced the longest decoloration time with citric, lactic and succinic acids as substrates. Furthermore, glycerophosphoric acid solution at the same concentration (pH 6·8) caused only a 35 per cent inhibition of growth. At 1/10,000 concentration, no difference was detected between the experimental seedlings and the controls

Estimation of the ascorbic acid content of the seedlings at the end of the twelfth day showed that whilst seedlings treated with 1/10,000 solution did not give greater values than the controls, those treated with 5/1,000 solutions gave 40–50 per cent increase in ascorbic acid content Johnson and Zilva[6] described several plants and fruits containing ascorbic oxidase with an optimum pH 5·0–7·0 It might be supposed that germinating and growing wheat seedlings contain an ascorbic oxidase which is inhibited in consequence of acid treatment This, however, cannot be so, since experiments have shown not only that ascorbic acid added to the wheat-germ extract of pH 6·8–7·7 is not oxidized more rapidly than the control, but even a protection against oxidation is observable. An ascorbic acid synthesis from the three substrates seems also unlikely, on account of an insignificant increase of ascorbic acid found in the case of 1/10,000 concentration. It seems likely that a disturbance of some regulatory mechanism of the ascorbic acid formation is responsible for the increased ascorbic acid content in the abovementioned cases. Monoiodoacetic acid has been tried to see whether this supposed regulatory mechanism is connected with the carbohydrate metabolism of the wheat-germ. Monoiodoacetic acid is highly toxic for the growth of the seedlings; even in a concentration of 1/10,000 it produces 55 per cent inhibition. However, it has no influence on the ascorbic acid content of the shoots.

Summing up the various observations made in the course of the present work, it was found that certain aliphatic acids are capable of influencing the growth, *germination and ascorbic acid production of the wheat* seedling. The divergent action of various acids and their connexion with the ascorbic acid increase of the germinating wheat seedlings obviously points to a complicated relationship between them and an ascorbic acid controlling system.

Details of the experimental results will be published elsewhere.

Glycolysis in Barley

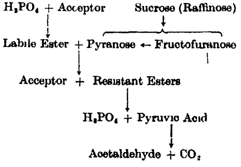
The sugars commonly present in barley tissues are the usual plant trio, sucrose, glucose and fructose. Their relation with the plant's respiration has been the subject of much investigation; the following scheme is based on evidence collected in my laboratory over several years.

Sucrose is always unstable in the tissues, and a high concentration can only be maintained by rapid synthesis; when this ceases, disappearance is rapid both in young seedlings[1] and mature leaves[2]. The breakdown of the sucrose is by hydrolysis yielding α β-glucopyranose and fructofuranose The fructofuranose reverts rapidly to α β fructopyranose but in the presence of cell catalysts is decomposed more rapidly than the pyranose Acetone preparations of young tissues will decompose fructofuranose arising in the hydrolysis of sucrose or inulin but will not attack either glucopyranose or fructopyranose The system is probably a zymase since it is active both in the absence and presence of oxygen and is not extracted by water There is an inverse relation between the rate of hydrolysis and the amount of sugar broken down, some component of the zymase being readily saturated

It seems sometimes to be supposed that the breakdown of fructofuranose would be incompatible with the occurrence of a phosphorylation cycle but this is not necessary in theory nor probable in fact The breakdown of pyranose which is suppressed by the acetone treatment certainly occurs in the living tissues The disappearance of sucrose from starving leaves is associated with a temporary accumulation of glucopyranose which is not enough to account for half the sucrose loss Fructose does not accumulate and the glucopyranose is soon broken down In germinating seedlings sucrose together with raffinose also a fructofuranoside is extensively consumed and during starvation hexose accumulation is again equivalent to less than half the loss of sucrose

Mr S E Arney and I have obtained evidence that these breakdowns are associated with phosphorylation The conflicting results of earlier work were probably due to the facts that young tissues always contain a large amount of free inorganic phosphate and that esterification is limited by the capacity of some acceptor Seedling tissues have been found to contain small quantities of a phosphate carrier which loses phosphate by hydrolysis at a rate similar to that of adenylpyrophosphate More stable esters are also invariably present and probably include hexosephosphates Under extreme starvation the rate of carbon dioxide production becomes proportional to phosphate supply With excess of free phosphate the respiration rate is still proportional in certain states to the concentration of phosphoric esters During starvation the esters more resistant to hydrolysis disappear faster than the labile carrier

The evidence at our disposal leads me to suppose that the following outline reactions are likely to occur during glycolysis



Phosphorylation and the decomposition of sucrose go on simultaneously The preferential decomposition of the fructofuranose may be due to its easier phosphorylation or to some entirely non phosphorylatory mechanism which is of little effect with pyranoses We cannot at present decide between these alternatives Whichever happens seems to be accompanied by the phosphorylation of pyranose some of which may be derived from reversion of the furanose itself

Pyruvic acid does not accumulate in any barley tissues we have examined but is very readily broken down by acetone and other dead preparations, as well as by the tissues themselves when alive Acetaldehyde is formed and carbon dioxide given off[2] These reactions will occur in the presence of atmospheric oxygen but we must reserve judgement as to their occurrence or suppression in the presence of respiratory oxidations

Details of these investigations will be published in a series of papers in the *New Phytologist*

Coagulation by Shearing and by Freezing

IN an attempt to find out how the most available silkworm (larva of *Bombyx mori*) makes the insoluble fibroin strands of its silk from the stiff water soluble fibroinogen paste which forms the cores of the contents of its silk depots two of the observations made have so much general interest that I send a brief account of them in the hope that others will either contribute to their explanation or direct attention to corresponding phenomena in other cases

(1) When the isolated fibroinogen paste is sheared by squashing it firmly between two flat plates of glass (or mica or Perspex) an irregularly striated semi opaque doubly refractive membrane is formed which is insoluble even in $N/10$ sodium hydrate solution and is far too thick to consist of hypothetical membranes coagulated by adsorption and rubbed off the surfaces of the plates

(2) After a not too dilute aqueous solution of the paste has been frozen solid by immersion in ice salt mixture at −13° to −17° C for a quarter of an hour and then allowed to thaw most of the fibroinogen is found to have undergone irreversible coagulation Certain salts (for example, 0 9 per cent sodium chloride) prevent this change

This coagulation by freezing might conceivably be either a special case of coagulation by shearing or a coagulation by electrolytes, since the protein and any other solutes would become steadily more concentrated as ice crystals increased, and growing ice crystals would shear the protein paste eventually produced If it is a coagulation by shearing, both observations would find a common explanation, and the one I would tentatively suggest is that, during the shearing contiguous fibroinogen molecules would be strained and distorted, and possibly activated and that while being thrust past their neighbours or rolled over them potentially mutually reactive hydrophil groups would be given opportunities to unite with each other, groups which in the unsheared paste would not be strained and would be kept apart by hydratation shells The fact that fibroinogen in aqueous solution is thermostable is in no way inconsistent with this suggestion

As bearing on coagulation by freezing, I should add that fibroinogen in aqueous solution, although thermostable, is nevertheless eminently surface coagulable, that is, like egg albumin, fibrinogen and certain other proteins[1] when adsorbed from aqueous or aqueous saline solution at interfaces with any gas or with various neutral oils, it promptly forms a coagulated surface membrane which can be dragged off as a thread, if traction is exerted on it while it is being formed and is still sufficiently plastic

This surface coagulability makes it necessary to state that the coagulation by freezing is far too massive to be explicable as coagulation solely at the surface of frozen out gas bubbles Further when *solutions of egg albumin are frozen coagulation is* limited to the surfaces of the frozen out gas bubbles

I had expected to find that coagulation by surface influence was responsible for the conversion into fibroin, but observation (1) and others an account of which will it is hoped appear shortly have led to the conclusion that absorptional coagulation proper has nothing to do with it and that the conversion is brought about either entirely or almost entirely by the shearing to which the paste is subjected in the silk channels

Added in proof, Dec 3 I now find that Foà[2] investigating spontaneously coagulable aqueous extracts of finely divided silk depots solutions which would contain much besides fibroinogen observed that freezing accelerated their *coagulation* and also that fairly thick layers of coagulated protein (doubtless surface coagulated W R) collected on solids dragged repeatedly from their free surfaces From this latter fact he inferred that the coagulation of depot content into the fibroin of silk was brought about by traction

Œstrogenic Activity of Anol, a Highly Active Phenol Isolated from the By-Products

IN a previous communication[1] it was suggested that the œstrogenic activity of crude specimens of anol and of the mother liquor from these preparations may be due to the presence of a polymer possessing an extremely high degree of potency The active substance has been isolated by the following procedure

Anethole was demethylated by heating in an autoclave with potassium hydroxide and alcohol The phenolic products were completely re methylated and from the mixture of methyl ethers anethole together with some *p* methoxy *n* propyl benzene was removed by steam distillation The residual thick oil was distilled at 0 15–0 2 mm when almost half passed over between 160° and 170° C and produced œstrus in rats with doses of 2 mgm This oil fraction was oxidized by treatment with finely powdered potassium permanganate in ice cold acetone and the products separated into anisic acid (i) α (*p* methoxy phenyl) *n* propyl methyl ketone (ii) and a saturated oil (iii) The production of (i) and (ii) demonstrates the presence among the products of demethylation of the di anol already described by us[2]

The saturated oil gradually deposited a small amount of a crystalline substance which, after purification, melted at 144° C and gave on analysis C, 80 7, H, 8 8, CH_3O, 20 1 per cent ($C_{20}H_{26}O_2$ requires C 80 5 H 8 8 CH_3O 20 8 per cent) When this substance was demethylated the resulting phenol melted at 184–185° C and gave on analysis C 79 9 H 8 2 per cent ($C_{18}H_{22}O_2$ requires C 80 0, H 8 2 per cent)

The phenol produced full œstrus response in all rats when administered in doses of 0 2 γ Doses of 0 15 γ gave 60 per cent and doses of 0 1 γ gave 20 per cent response

The substance proved to be identical with the 4 4 dihydroxy γ δ diphenyl *n* hexane produced by hydrogenation in presence of palladium of 4 4 dihydroxy γ δ diphenyl β δ hexadiene[3] or of 4 4′ dihydroxy α β diethyl stilbene[4] although in poor yield from the latter

A full account of the synthetic work on these substances is now being prepared and will shortly be submitted for publication in collaboration with Mr L Golberg and Prof R Robinson

Trimethylamine in Menstruous Women

HAVAS's recent communication in these columns[1] on the suggestive hormonal properties of trimethyl amine recalls the fact that it was so long ago as 1902 that Michin[2] first directed attention to the presence of trimethylamine in the vaginal secretion of women Michin carried out his investigations on Russian women Briefly his findings were as follows

The percentage of trimethylamine in normal women varied between 0 07 and 0 72 with a mean of 0 33 In women with various genito urinary disorders the range was 0 00 0 64 per cent

Cases with metastatic tumours were associated with a significant increase in the amount of trimethyl amine, more benign tumours with a less appreciable increase In *primiparæ* the average amount was 0 30 and in secundiparæ 0 29 During parturition the amount is between 0 1 and 0 86 per cent with a mean of 0 31 In four out of nine women at the climacterium no trimethylamine was found and in five others it was more or less reduced In post menopausal women trimethylamine was altogether absent Trimethylamine was found to be very bactericidal and in a solution of 1 15 000 completely inhibited the growth of most bacteria and reduced the activity of others

It is of interest here to note that in 1927 Klaus[3] obtained trimethylamine from the menstrual discharge and in 1930 Lanczos[4] found that a preparation of frog's gastrocnemius muscle loses excitability when either the nerve or the muscle is treated with dilute solutions of trimethylamine She also found that the same effect is obtained when these structures are held by a menstruous woman for 10 15 minutes This suggests that trimethylamine may be excreted through the skin during menstruation and that the deleterious effects which the contact of menstruous women are said to exert upon such things as hams, preserves, bread, wine, and flowers, may be attributable to the action of this substance. Experiments which I have had under way for some time lend strong support to this suggestion

Temperature Influence on the Pressure Broadening of Spectral Lines

THE classical theories of pressure broadening of spectral lines given by Lorentz[1] and by Weisskopf[2] lead to the following intensity distribution in an absorption line.

$$K_\omega = \text{Const.}\ \frac{\gamma}{(\omega-\omega_0)^2}, \qquad (1)$$

subject to the condition $\omega \gg \gamma/2$. Here $\gamma/2$ is the number of collisions per second of the absorbing atoms with the perturbing ones, K_ω the absorption coefficient for frequency ω, and ω_0 the frequency corresponding to the centre of the line. If the concentrations of absorbing and perturbing atoms are constant, Lorentz's theory predicts $\gamma \sim \sqrt{T}$, where T is the absolute temperature of the gas Taking into account Weisskopf's relation between impact diameter and relative speed of colliding atoms, we find $\gamma \sim T^{3/10}$. Under special conditions, relation (1) follows as a limiting distribution from the wave-mechanical theory given by one of us[3,4]. In this theory, the width of spectral lines does not depend directly upon the number of collisions per second, although it does depend upon the kinetic energy of colliding atoms and upon the shape of potential curves.

So far as we know, Orthmann[5] was the only one who investigated the dependence of line broadening upon temperature at constant concentration of absorbing mercury atoms as well as of perturbing hydrogen molecules. His results agreed with the theory of Lorentz. We have investigated the broadening of the Hg absorption line 2537 A. caused by helium at the concentration of $8{\cdot}8 \times 10^{14}$ mercury atoms and $1{\cdot}24 \times 10^{19}$ helium atoms per c.c. The gases were contained in a silica tube 150 cm. long. The absorption spectra were photographed by means of a Hilger quartz spectrograph (dispersion 1·6 A./mm.). As is well known, the lines broadened by the presence of light gases show a symmetrical intensity distribution similar to that given by the relation (1). It is usually thought now, that in this case the broadening is due mostly to the so-called collision damping effect, which depends upon the temperature; the role of statistical effect, which does not depend upon temperature, should be negligible. The use of a mercury-helium mixture enabled us to vary the gas temperature within very wide limits without changing the atom concentration.

It is well known that the total quantity A of light absorbed from a continuous background (as well as the surface limited by the curve in the accompanying graph) by a line with intensity distribution given by (1) is, *caeteris paribus*, proportional to the square root of the line width:

$$A \sim \gamma^{1/2} \qquad (2)$$

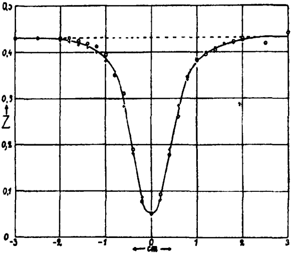
when the absorbing layer is sufficiently thick. Lorentz's theory leads in that case to

$$A \sim T^{1/4}; \qquad (3)$$

whereas that of Weisskopf leads to

$$A \sim T^{3/20}. \qquad (4)$$

We think that our measurements were sufficiently precise to show the effects predicted by the relations (3) and (4). The accompanying graph shows an absorption curve obtained from absorption photographs taken at 398° K. (crosses) and at 1198° K. (circles); the blackenings of continuous background given by the hydrogen discharge tube were reduced to constant intensity. The curves for both these temperatures are seen to be identical within the limits of experimental error (for the lower temperature the surface limited by the curve is about 4 per cent greater than the surface limited by the curve corresponding to the higher temperature; but this difference lies within the limits of experimental error). This result indicates that the broadening of the Hg absorption line 2537 A. caused by helium does not depend appreciably upon the temperature.



HG ABSORPTION LINE 2537 A. BROADENED BY HELIUM. BLACKENING OF PHOTOGRAPHIC PLATE AS FUNCTION OF DISTANCE FROM CENTRE OF LINE. + ABSORPTION SPECTRUM AT 398° K., ○ ABSORPTION SPECTRUM AT 1195° K.· 1 CM. CORRESPONDS TO 0 23 A.

Similar researches upon the influence of other gases upon the mercury line 2537 A. will be undertaken shortly.

Humidity in the British Isles

IN an article in NATURE of August 20, p. 365, "Humidity in the British Isles", it was stated, referring to Stacey's figures: "It is difficult, however, to draw any useful conclusions from charts and averages based on observations at 9 h., an epoch at which relative humidity is normally in process of descending from the early morning maximum to the afternoon minimum".

I would like to suggest that, on the contrary, readings taken at 9 h. can provide very useful conclusions, because the humidity at that hour approximates very closely to the average over the 24 hours.

In connexion with the moisture content attained by wooden articles in use, this Laboratory wished to arrive at the simplest way of measuring the average hygrometric conditions prevailing, and to that end I had observations of temperature and humidity taken every three hours over a period of years in several types of environment

In so far as outdoor shade conditions are concerned, it was found that the readings taken at 9 a.m. were nearer to the average over the twenty-four hours than any other single reading. For example, the average difference between them was less than 2 per cent humidity, and the maximum difference 6 per cent, throughout the period April 1934–December 1935. For many purposes this is sufficiently accurate. When an unheated shed such as a timber store was under consideration, it was found that the readings taken at midnight were within 1 per cent humidity of the average. In a heated room such as a museum or other public building, where the number of persons normally present is small relative to the size of the room, the readings taken at 11 h or noon were within 1 per cent humidity of the average during the heating season October–March

The above figures indicate, I think, that for purposes where close accuracy is not essential, it is not necessary to go to the expense of obtaining recording apparatus or the trouble of making frequent readings, and data such as those compiled by Stacey can be usefully applied.

It is not denied that observations made at 7 h., 13 h and 18 h do cover a wider sphere of usefulness, but the 9 h. observations appear to approximate more closely to the daily average humidity than even the average of the three observations mentioned above At Kew in 1935, the average daily humidity (0–24 h) was 77 per cent, and at 7 h, 13 h and 18 h it was 84, 66 and 70 per cent respectively (average 73 per cent)

Points from Foregoing Letters

AN explanation of the effects observed in interferometric studies of light scattering in fluids and solids is given by Sir C. V. Raman and Dr. C. S. Venkateswaran. They put forward the principle that the frequency of the scattered light is the sum or the difference of the frequency of the material particles and of the radiation frequency. The scattered light should in general exhibit a continuous spectrum with maxima of intensity depending upon the direction of observation, rather than discrete frequencies as suggested by Brillouin's theory.

A. Mozley points out that the molluscs in the Sub-Arctic Region belong to archaic groups which in former times were predominant over the whole world; also that, with the exception of those of Lake Baikal, they show a lower tendency for new species formation. He ascribes this, apart from the possible effect of lower temperature, to the sameness of the environment over vast tracks in the Sub-Arctic Region.

Prof. D. Kostoff gives a list of the characters which change when the number of chromosomes in the nucleus of certain plants has become multiplied through polyploidy. These include the volume of the cells, thickness and breadth of leaves, size and weight of ovules, seeds and anthers. He points out that while the nature of the changes brought about by mutation are unpredictable, the direction of hereditary variations conditioned by euploid chromosome alterations can be predicted and are therefore of great agricultural value.

A hypothesis is offered by H. Klingstedt with the view of putting on a common genetical basis the sterility in species-hybrids and the sterility caused by recessive genes within species.

Fumaric, malonic, oxalic and pyruvic acids in concentration of 5/1,000 are found by Dr. E. Gal to inhibit completely the germination of wheat seedlings; with citric, succinic and lactic acids 60–70 per cent inhibition occurs, whilst glycerophosphoric acid of the same concentration gives only 35 per cent inhibition. An increase of 40–50 per cent in the amount of ascorbic acid present is observed, but the exact nature of the inhibitory mechanism is not yet clear

Dr W. O James submits an outline of the stages by which sugar is oxidized to acetaldehyde and carbon dioxide in barley during the plant's respiration. The following changes: sucrose → fructofuranose (+ α-β-glucopyranose) → pyranose → resistant esters → pyruvic acid → acetaldehyde, take place, and a phosphorylation cycle goes on simultaneously with the decomposition of sucrose.

Dr. W. Ramsden finds that shearing and freezing of fibroinogen paste of the silkworm produces coagulation, and directs attention to similar observations made by Foà in 1912.

H. Horodniczy and Dr. A. Jabłoński find that the width of the mercury absorption line 2537 A. broadened by admixture of helium (at constant concentration of mercury and helium) does not depend appreciably upon the temperature of the absorbing gas, as would be expected from the theories of collision damping given by Lorentz and by Weisskopf.

R. G. Bateson suggests that humidity readings taken once daily only may compare very closely with the average over the 24 hours provided that the appropriate hour is selected.

Research Items

Intoxication and Resistance to Infection

KENNETH L PICKRELL (*Bull Johns Hopkins Hosp* 63, 238, 1938) records his experiments on rabbits in which he studied the effect of alcoholic intoxication and ether or avertin anæsthesia on resistance to pneumococcal infection He found that alcoholic intoxication maintained at the point of stupor destroyed resistance to pneumococcal infection in these animals their immunity being lost even when they had been rendered highly immune by intravenous injection of anti pneumococcus serum Their loss of resistance to infection appeared to be due to the fact that intoxication profoundly inhibited the vascular inflammatory response while intoxication was maintained and in the absence of capillary dilatation and of margination of the leucocytes, leucocytic emigration at the site of infection was negligible and the bacteria therefore proliferated uninterruptedly Similar effects were obtained with ether or avertin anæsthesia

Rotter's Test for Vitamin C Deficiency

A G Zoccoli and V Lombardo (*Riforma med* 54, 1489, 1938) refer to the intradermal test described by H Rotter of Budapest (NATURE, 139, 717, 1937) for determining the degree of saturation of the organism with vitamin C, and record their own investigations on guinea pigs and human subjects The test depends upon the fact that 2 6 dichlorphenolindophenol is discoloured by the tissues at a rate depending upon the ascorbic acid content When small quantities of the dye are injected into the sole of a guinea pig, decoloration takes place much more rapidly in healthy than in scorbutic animals The value of the reaction as a rapid clinical test for vitamin C deficiency was confirmed by Portnoy and Wilkinson (*Brit Med J* 2 328, 1938), but not by the present writers, though they admit that with certain modifications the test may be of some use

Increase of Gannet Colonies in Shetland

IN a short article upon the gannets of Shetland, James Fisher, Malcolm Stewart and L S V Venables give some figures which illustrate in a remarkable way the rapid increase which may take place following upon the colonization of new and suitable haunts (*British Birds*, 32, 162, 1938) In 1914, Noss island had a single pair of gannets, in 1918, three young were reared, two years later there were 10 pairs, and since that time numbers have increased by leaps and bounds until in 1938 a careful count revealed the presence of 1518 breeding pairs, with presumably an unknown but very considerable number of non breeding birds attached to the colony The second Shetland colony, at Hermaness, probably started in 1917, and in 1938 its breeding pairs numbered 2045 There is nothing here to suggest that the gannet is on the wane in British seas, a fear expressed in a letter recently circulated in the daily newspapers

Californian Hepatics

DR D H CAMPBELL has recently given a short account of the prolific hepatic flora of California (*Ann Bryologici* 11 1938) This rich flora is interesting in view of the climatic conditions of alternation of an almost rainless summer with a wet season Of the numerous genera of thallose forms *Sphærocarpus* is the only annual The larger types become dried, but the tissues of the younger regions and sometimes the young sex organs, resist the drought in a surprisingly short time after the first rains, such species mature their reproductive organs *Sphærocarpus* growing from spores appears rather later Some species of *Fossombronia* and notably *Geothallus tuberosus* survive the dry season by tuber formation and it is evidently in this condition that *Geothallus* was introduced in soil from San Diego, where the low rainfall apparently seldom induces thallus development from the tubers The thallose liverworts of this region are either cosmopolitan species or, for the most part, confined to the Pacific coast, and show little relation to the species of the eastern United States The foliose Acrogynæ are little represented in comparison with thallose types, and their relationships are on the whole rather with European than with species of the eastern United States

Fungi of India

THE publication of the Fungi of India by Butler and Bisby in 1931 marked the beginning of a period of more exact mycology in India Records up to the year 1930 were enumerated, and it was only to be expected that during the eight years now past, an imposing number of fresh records would be made These have been collected by Dr, B B Mundkur into a supplementary volume (Imp Counc. Agric Res, Sci Monograph No 12 Pp 54 Delhi Manager of Publications Rs 1 6, or 2*s* 3*d* 1938) Myxomycetes have been included in the present compilation, and the mycological flora of India now possesses 2868 species—an increase of 517 over those previously published Plant pathogens and parasitic fungi predominated in the earlier volume, but the extension of mycological work, during recent years, to include studies of soil organisms, coprophilous fungi, and aquatic moulds, is well reflected in the supplement A new species, *Mycosphærella tinosporæ*, has been constituted in the present account, following the discovery by Ajrekar and Oza of the ascigerous form of *Cercospora tinosporæ* Syd The fungus flora of India has yielded few novel taxonomic groupings This is probably due, however, to a gratifying restraint in the evaluation of supposed new forms by those who have prosecuted the work of collecting and tabulating the records, both in the original volume and in the present supplement

A Lignicolous Fungus

THE common agaric, *Collybia radicata*, is well known to students of mycology by virtue of the long 'rooting' base to the stipe Fries pointed out so long ago as [illegible]821 that the root was connected with a subterranean tree root, and in a recent paper, A H Campbell considers its biological effects upon the host (*Trans Brit Mycol Soc*, 22, Pts 1 and 2 151–158, Aug 1938) The vegetative mycelium produces a white rot in the root of the tree, followed by delignification Limiting plates are also formed in the wood by the cementing together of cells with a brown substance very similar to the formation of sclerotia The fungus can also be grown to yield viable spores in pure culture and here also, averting mycelia or brown plates are formed if other cultures are reached The term pseudosclerotium is proposed for such limiting plates

Peach Mildew in Egypt

THE peach is the most economically important of stone fruit trees in Egypt but its fullest yield is prevented by widespread attacks of the peach mildew fungus *Sphærotheca pannosa* var *persicæ* Dr Amin Fikry has investigated methods for the control of this disease (*Min Agric Egypt Tech and Sci Serv Bull* No 183, 14 pp + 7 plates Gov Press Bûlâq Cairo, P T 3 1937) Symptoms of the malady its distribution host relations and the climatic or edaphic factors affecting parasitism, are all described in detail and are further illustrated by the plates Lime sulphur washes either home made diluted 1 in 10 or commercial concentrates diluted to 1 in 200 were found to give complete control after three applications, whilst amberene (sodium polysulphide) was also effective The addition of 0 2–0 5 per cent of soap was found to be necessary when trees with young fruits were to be sprayed, in order to wet the bloom which appears at this stage The first appearance of the disease seems to vary according to the height of the Nile flood but spray treatment must be given as soon as symptoms are noticed

The Potato Virus X

ONE of the chief difficulties of research into virus diseases of plants has been to account for discordant and puzzling observations upon the appearance of symptoms caused by a supposedly single or pure virus The conception of a disease caused by a virus complex or mixture of viruses is now firmly established, but a monograph of the potato virus X by Dr R N Salaman takes the conception still further and establishes the existence of at least six strains of this particular virus (*Phil Trans Roy Soc Lond* B, 229, 137–217 Sept 1938) All strains have particles of similar size are composed of the same nucleoprotein, and produce inclusion bodies within the tissues of their hosts They vary in the degree of dilution which they can withstand and in the severity and type of symptoms they produce upon various hosts A ten fold excess of a weak strain over a strong one may lead to the masking of the latter Several other mixtures are considered and make it possible to explain the appearance of particular types of symptoms Conversion of one strain to another, involving a loss of virulence has been established, and it is held that such conversion is a [illegible]on Questions of acquired immunity, of the [illegible] of virus particles to genes, and many other problems are further considered The only anxiety amongst Dr Salaman's adequate wealth of detail is that future classification of viruses should provide an arena for taxonomic lumpers and splitters , but that very detail directs the problem more to the physiologist than to the systematist

Recent Large Earthquakes recorded at Stuttgart

THANKS to Dr W Hiller we are able to report that earthquake shocks producing very large amplitudes on the seismograms were recorded at Stuttgart at the following times 1938 Nov 5 8h 55m 52 5s, 11h 2m 45 5s Nov 6 9h 6m 25s and 21h 51m 18 5s all in G C T The epicentre of the first of these was estimated to be at a distance of 9550 km from Stuttgart in a direction N 35° E and to be probably in the Pacific Ocean fairly near the coast of Japan The others were probably aftershocks from near the same epicentre and the first pulses in each case were compressional The first two shocks showed evidence of some considerable depth of focus in that the *pP* pulse (that is a primary pulse from the focus reflected immediately at the earth s surface before proceeding) first recognized by Scrase was recorded on November 5 at 8h 56m 19s and at 11h 3m 20s All these shocks show correlation with those recorded at Kew Observatory the depth of focus of the first shock being estimated from the Kew records to be about 75 km which is considerably below normal

Structures of Some Compounds

THE electron diffraction method has been used by K J Palmer (*J Amer Chem Soc* 60 2360 1938) in investigating the molecular structures of some relatively simple compounds The interatomic distances and angles were calculated It was shown that sulphuryl chloride (SO_2Cl_2) vanadium oxychloride ($VOCl_3$) and chromyl chloride (CrO_2Cl_2) have tetrahedral configurations which are however considerably distorted Thionyl chloride ($SOCl_2$) is pyramidal and sulphur trioxide (SO_3) is planar Sulphur chloride (S_2Cl_2) has one chlorine atom attached to each sulphur atom The S—O distances in SO_2 (previously measured by Cross and Brockway) SO_2 $SOCl_2$ and SO_2Cl_2 are nearly equal and from 0 06 A to 0 09 A shorter than the sum of the normal double bond radii which is 1 52 A It is concluded that excited electronic structures in which double and triple S O bonds are present must make a considerable contribution to the normal state of these molecules these are more important for thionyl and sulphuryl chlorides than for sulphur dioxide and sulphur trioxide

Ions in Solution

IN a comprehensive review of the present position of the physical chemistry of electrolytic solutions by several contributors, recently published (*J Franklin Inst* 225 623–743 1938) H S Harned describes the thermodynamic aspect as related to the Debye Huckel theory this includes a survey of activity coefficients as determined by several independent experimental methods and the close agreement between these is emphasized The case of weak electrolytes in salt solutions is included It is concluded that the development of these methods in the study of equilibria has reached a stage where a reliable and accurate body of evidence is becoming available The conductivities of aqueous solutions is reviewed by D A MacInnes who discusses the validity of Onsager's equation which holds accurately for very dilute solutions whilst for more concentrated solutions semi empirical equations are available Solutions in non aqueous solvents are considered by C A Kraus who concludes that a solution of the difficult problems in this field will not be found through a mere extension of the limiting laws which hold only at very low concentrations and that much more experimental work is required Kinetics in ionic systems is the subject dealt with by V K La Mer the primary salt effect the secondary salt effect generalized acid base catalysis and the effects of temperature are the main topics reviewed The derivation of ionization constants and limiting con ductivities from conductivity measurements is con sidered by T Shedlovsky The papers are accom panied by bibliographies

Capture of Orbital Electrons by Nuclei

ACCORDING to the Fermi theory of β ray emission the electrons or positrons are created at the moment of ejection by a neutron proton or proton neutron transaction Yukawa suggested that an alternative process to the emission of a positron might be the capture of an electron from the outer atom This process might occur in cases where the energy available was insufficient for positron creation L W Alvarez (*Phys Rev* 54 486 1938) discusses the evidence for electron capture The capture of an electron from say the *K* shell is followed by the rearrangement of the orbital electrons and the emission of a characteristic X ray of the daughter element Soft X rays of the right absorb ability have been observed from the artificially radioactive vanadium isotopes which are formed by deuteron bombardment of titanium In this case, positrons are also present (probably from the decay of another isotope), and the evidence for electron capture is not quite conclusive as the X radiation may have been excited in some other way A more conclusive proof was obtained by studying the activity of a gallium isotope obtained by deuteron bom bardment of zinc followed by chemical separation An electron spectrum from this substance was found to be due to internal conversion of a γ ray of 100 kv energy An X ray emission was found by absorption measurements to be definitely characteristic of zinc, but no positron emission could be detected and it seems certain that the gallium isotope decays to zinc exclusively by electron capture The zinc X rays are then formed by rearrangement of the orbital electrons The author considers that electron capture processes also occur in the cases of ^{180}Ta, ^{40}K, ^{65}Zn, ^{197}Hg, ^{106}Ag, Cd, ^{7}Be ^{54}Mn, and that it explains features of the decay of these artificially radioactive atoms which were formerly unsatisfactorily explained

Photographic Sensitivity at Low Temperatures

ACCORDING to the theory of Gurney and Mott, the production of the latent image depends on the photo-electric removal of an electron from a bromine ion into the conductivity band, in which it moves until it is trapped by a region of low potential, the sensitivity speck In the next stage, positive silver ions move up to the charged speck This ionic move ment should be very slow at low temperatures, and the sensitivity of photographic materials might be expected almost to disappear at very low tempera tures W F Berg and K Mendelssohn (*Proc Roy Soc*, A, 168, 168, 1938) have investigated the sensitivity of a process emulsion at room temperature, liquid air and liquid hydrogen temperatures. The sensitivity changes little between liquid air and liquid hydrogen—it is of the order of 5 per cent of the sensitivity at room temperature, and consider ably higher than would be expected on the Gurney Mott view At low temperatures separate variations of light intensity and exposure time have no effect on the final blackening if their product remains constant—there is no failure of the reciprocity law as at room temperature It is suggested that at low temperatures the electronic changes only take place the electrons freeze into the lattice and the ionic movements only occur on warming up At room temperature the simultaneous occurrence of electronic and ionic movements is connected with the failure of the reciprocity law

Ionosphere Radio Waves

WHEN a radio beam of angular frequency ω is propagated upwards and reaches an ionized region having N electrons per c c of mass m and charge e each of which collides with a molecule on the aver age ν times a second and the region is the seat of a magnetic field H the beam is split up into two which travel with different velocities and are polarized and absorbed differently The beam less influenced by the magnetic field is known as the ordinary and that more influenced as the extraordinary beam The calculation of the polarization of each beam, and the refractive index and absorption of the medium for it from ω N m e and ν is a laborious process and Prof V A Bailey, of the University of Sydney four years ago devised a graphical method of reducing the labour In the supplementary number of the *Philosophical Magazine* of November, he describes, in co operation with Prof J M Somerville of Armidale University College, New South Wales, a numerical method of computation which is very rapid They cal culate first the polarization, then the refractive index and finally the absorption They introduce three subsidiary functions which enable them to give the calculations on a page of the journal for the ordinary and extraordinary beams due to two incident beams

Law of Error

IT has been wittily remarked that mathematicians accept the normal law of error because they believe that it has been proved by experiment while experi menters believe that it has been proved by mathe matics A searching criticism of both bases of sup port has been given by Dr H Jeffreys (*Phil Trans Roy Soc* A 237, 231, 1938) The mathematical proof rests on the hypothesis that the error of any individual observation is the resultant of a large number of comparable and independent observations Even if this hypothesis is accepted, it is not proved that the result applies to errors of any magnitude As for the experimental facts, Karl Pearson long ago showed that there are substantial departures from the normal law Dr Jeffreys confirms this by a very detailed examination of seven sets of observations He arrives at the important conclusion that the true law governing errors in astronomy and physics is not the normal law, but one of the Pearson type $y = k(1 + x^2/2m\sigma^2)^{-m}$, with the index m between 3 and 4 The effect of the change is to increase the probability of occurrence of large random errors It appears that a number of discrepancies in experimental read ings that have been reckoned as systematic are, after all, possibly merely random

Commemoration of the Discovery of Radium

WITH the "Semaine internationale contre le Cancer", which took place at Paris between November 23 and 30, the fortieth anniversary of the discovery of radium by Pierre and Madame Curie was commemorated. Simultaneously, the discovery of the electron, the X-rays, and Hertzian waves was celebrated. The importance of recent discoveries, which are now occupying the attention of contemporary workers, is easily over-estimated, and, making due allowance for this possibility, we feel justified in considering the discovery of radium to be one of the outstanding events of the history of science. It promoted to a higher degree than any other discovery the development of the science of radioactivity, which has so deeply influenced our outlook on the nature and formation of the chemical elements, and simultaneously supplied a tool of outstanding importance alike to various branches of science and to medicine.

France is rightly proud of a great son, French by birth, and a great daughter, French by adoption, and has solemnly commemorated the fortieth anniversary of the discovery of radium. The opening of the "Semaine internationale contre le Cancer" took place at the Sorbonne. The broadcast of the President of the Polish Republic from Warsaw, in which the memory of the great daughter of Poland and her achievements were recalled, was eloquently answered by M. Lebrun, President of the French Republic. Among those present were also Mme. Dluska, the sister of Mme. Curie, and the latter's daughters Irène and Eve, Miss Johanna Hertz, daughter of the late Heinrich Hertz, and the Marchesa Marconi.

The gathering was also addressed by various representatives of the French Government, and on scientific topics by Jean Perrin, Maurice de Broglie and Langevin, who gave a short survey of the physics of the electron, the X-rays and Hertzian waves respectively, while Gutton described the technical application of the Hertzian waves, and Gendrean gave an eloquent description of the life work of Pierre and Marie Curie.

The addresses delivered on the following days dealt with biological and physical topics, with the exception of that of Rowntree, who discussed the efforts made in Great Britain in cancer therapy. Schinz discussed the possibilities and limits of the treatment of cancer by use of various radiations. The utilization of biological reactions in measuring X-ray doses was the subject of a lecture by Carter Wood, who has found in the eggs of *Drosophila* the most suitable biological material. The application of radioactive indicators in biology was discussed by Hevesy, that of the electron microscope by Marton, while Errera spoke on the effect of Hertzian waves on macromolecules. Bernal's lecture dealt with the elucidation of the structure of the virus by the use of X-rays. Several physical topics were discussed as well. The only surviving assistant of the late Heinrich Hertz, Prof. Bjerknes, gave an illuminating survey of Hertz's work. Louis de Broglie gave a lecture on the wave character of the electron, followed by G. P. Thomson, who discussed the phenomena of electron diffraction and its applications. Several lectures dealt with technical topics, including a lecture by Bouwers, who discussed the production of different kinds of penetrating radiation, mentioning the construction of a sealed X-ray tube at Eindhoven operated at one million volts.

The lectures were given at the Palais de la Découverte, which contains such a wealth of exhibits showing the trend of scientific progress in the most diverse fields in an unsurpassingly inspiring and instructive way—a fitting frame for the celebration of the fortieth anniversary of the discovery of radium.

G. H.

The Imperial Bureau of Dairy Science

IN 1936 the British Commonwealth Scientific Conference which met in London to consider the working of the organizations controlled by the Executive Council of the Imperial Agricultural Bureaux, recommended that a new Imperial Bureau of Dairy Science be established. The conference also suggested the National Institute for Research in Dairying as the most suitable place for the Bureau.

Following agreement by all the authorities concerned, the new Imperial Bureau of Dairy Science has now been established at Shinfield, near Reading. Prof. H. D. Kay, director of the National Institute for Research in Dairying, has been appointed director of the Bureau. Mr. W. G. Sutton, from Massey Agricultural College, New Zealand, has been appointed deputy director and has now taken up his duties. The Bureau is financed co-operatively by the Governments of the British Empire in the same way as the other Imperial Agricultural Bureaux.

The functions of the Bureau are to index research work in dairy science, whether carried out in the Empire or elsewhere; to collect, abstract and collate information bearing on dairy science and to distribute such information both by publication and by private communication to research workers, officials and advisory officers throughout the Empire. In addition the Bureau is charged with the duty of establishing and maintaining contact between research workers with common interests, promoting conferences of workers and visits to research centres, and in general encouraging the circulation of information, ideas, material and personnel.

The field of dairy science to be covered by the Bureau was defined by the Conference when recommending its establishment. This field includes the microbiology, chemistry and physics of milk and its products; animal diseases in so far as they affect milk and its products; the technology of processing milk and manufacturing dairy products; the physiology of milk secretion as affecting quality and quantity of milk and dairy products, standards for the composition and quality of milk and its products

The routine duties of the Bureau, such as indexing and abstracting will already be familiar to many dairy workers from the activities of the Bureaux already established in other subjects An aspect of Bureau work which may not be so well known and understood is the more informal service which can be given to research workers, teachers and field officers The Bureau will deal directly with the individual workers in dairy science, who are invited to write to the Bureau for information which is not obtainable in their own countries The Bureau may be able to supply the information itself, or to put the inquirer in touch with someone who can do so more effectively

The new Imperial Bureau of Dairy Science has been established in answer to requests for a clearing house for information in dairy science, its value to dairy science and to the dairy industry generally, will largely depend on the extent to which research workers and others avail themselves of its services

Algeria To-day

A SERIES of illustrated books on Algeria and its institutions, published during the past two years by the Gouvernement Général de l'Algérie, Algiers, coupled with a recent visit to the country, has prompted the following notes

Algeria is a land of contrasts The co operation of two widely different races and faiths over a century of steady progress, has turned a land which was dreaded in the past for the daring of its pirates into a country where agriculture, social conditions, art and learning are developed to a high degree

Owing to its excellent organization, its importance as a capital and to its easy accessibility, Algiers is often the venue of international meetings dealing with technical problems, such as the production of wheat wine, minerals, or again civil engineering, industrial chemistry anthropology, archæology and medicine Such occasions provide excellent opportunities for scholars and technicians to see a good deal of the French North African provinces

Algiers itself is worth a thorough visit East and West meet in that ancient capital of the deys, whose palace still dominates the white agglomeration of the Kasbah But the European town itself has grown considerably, thanks to an enlightened policy of public works which have really placed it among the most modern towns of the Mediterranean[1] What adds to the interest of Algiers, besides its museums, botanic gardens and well equipped hospitals, is its fully organised University, which, for the past twenty five years, has been the centre of the intellectual life of the country The faculty of arts, which includes a newly formed department of philosophy under Prof Mesnard, the faculty of science, with its well-appointed laboratories, such as that of industrial physics under Prof Verain, the faculty of laws, which is particularly important owing to the existence of two legal systems in the country, and the faculty of medicine, with its up-to-date hospitals and medical research stations—all are very active and occupy an eminent rank in higher education, thanks to the results obtained in all fields by its professors and research workers In spite of the economic crisis and the difficulty experienced by students leaving the University in obtaining posts, an average of about 2,500 students of both sexes are registered in each year

If Algiers has the only university of French North Africa, there are three higher colleges of Moslem civilization, the Medersas of Algiers, Constantine and Tlemcen But it should be mentioned that only a small percentage of the Algerian native population receives any education at all There are not sufficient schools to meet the demand for elementary education for native children, in spite of the efforts of an administration hampered by lack of funds This can be inferred also from the large number of children in the streets and lanes, especially in the villages of the south

It must be said to the credit of the authorities, however, that they spare no efforts to improve the situation[2] But they are not always helped by the natives as some of them are apt to consider official education as an attempt to interfere with their religion and customs, and with the authority of the parents over their children, while others prefer to use their boys and girls for domestic or farm work In spite of this, there are roughly 60 000 boys and 6 000 girls in the 800 native elementary schools against about 75,000 boys and 75,000 girls in the European elementary schools It is interesting to note also that there are about 2 900 Koranic schools in Algeria, with about 44,000 pupils

Technical and agricultural instruction is given to boys in a few up to date institutions which have about 3,000 pupils, one fourth of whom are natives The girls are taught domestic economy, carpet weaving and embroidery in various institutions supervised to a large degree by religious orders, such as the famous Pères Blancs and Sœurs Blanches, the apostles of the desert There are also professional training centres a pottery-school, a ceramic school and a wool-craft centre The Algerian arts and crafts centres of the town of Tlemcen have a high reputation in North Africa a magnificent saddle embroidered with gold, which was made at these centres, was presented to the King of Egypt on the occasion of the recent Cairo exhibition

Though Algeria is not regarded as an industrial country, it offers a wide field for agricultural study and experiment The northern plains and high plateaux offer excellent opportunities for farming cereals, vineyards, vegetables, olive oil, tobacco cotton and wool are produced in great quantities They compete on the French market with the home produce, and often cause friction between Algerian and French interests—a sore point for the administration of both countries It may be worth mentioning here that, after France and her colonies, the United Kingdom's trade with Algeria is more than double that of any other country Algeria imports about one million pounds worth of goods from England, and exports about 1 25 millions in value

The development of the oases of the south have opened up the desert, so to speak, to regular exploitation Owing to lack of water, this policy of development has to be slow But the results already obtained between Touggourt and Biskra, along the Oued R'ir, are most promising The co operation of the local proprietors, such as the Cheikh El Arab ben Gana, who is the head of all the Arabs of North Africa, is an invaluable asset for the progress of the country As things stand at present, there are most interesting comparisons to make from this point of view, with the methods used in Irak, Egypt and Libya for the exploitation of the desert belt of North Africa and Asia Minor

Algeria is of great importance for the historian and the geographer The imposing ruins of Timgad and Djemila[3] are an epitome of Roman history, and a testimony to the genius and power of Rome[4], while Islamic civilization has left lasting marks throughout this rich land[5] A curious experience is offered by the M'zab country, the home of the Puritans of Islam, who fled right into the desert to escape the persecutions of the orthodox Moslems, and founded there the interesting towns of Ghardaia and Guerrera and other villages, where they keep intact their religious laws and customs[6]

Then there is the unique experience offered by the Sahara, which is now open to regular traffic from one end to the other[7] The geography, geology, flora and fauna of this vast tract of land are now objects of systematic study Among the most notable achievements of French scholars in this field of research are the results obtained by Prof Reygasse, head of the Anthropological Museum of Algiers, during his expeditions in the fastnesses of the Hoggar, the land of the Tuaregs There he discovered distinct signs of a primitive civilization, which was mentioned by Herodotus The carvings and rock paintings, some of them twenty feet high, which he discovered in the Hoggar mountains, that rise to more than 8,000 feet, are among the most precious specimens of prim art

Future Developments in Coal Treatment and Utilization

THE future of coal is of interest in some form or another to modern industries of all kinds, but is of special interest to the technicians and industrialists of the Tyneside area This gave special importance to the symposium on 'Future Developments in Coal Treatment and Utilization' arranged by the Newcastle on Tyne Section of the Society of Chemical Industry at King s College, Newcastle on Tyne, on December 7 last The papers dealt with quite different aspects of fuel technology, and the change of point of view of the speakers was stimulating where a similar series of papers all on the same lines might have been tiring

The papers by Dr W T K Braunholtz and by Dr E W Smith can be considered together The first was a careful survey of the growth of research in the gas industry from the early days of individual effort to the organized research of to day which embraces all subjects of interest to the industry, from retort refractories to ammonia recovery The organized work of to-day is in the hands of the Institution of Gas Engineers and of the collaborating organizations Dr Braunholtz directed attention to the important effect of former researches and hinted that the future might witness remarkable advantages in the technology of gas production He was referring, no doubt, to the Institution's researches at the University of Leeds on the complete gasification of coal or coke with hydrogen under pressure He visualized a future in which our domestic fuels will all be fluid, stating that the open grate must eventually disappear Although Dr Braunholtz may be right, it must be said that, at the moment, the development of smokeless fuels is actually stimulating interest in the open grate

Dr E W Smith took up the story where Dr Braunholtz left off, but treated the subject more from the economic point of view He started by postulating the importance of administration, without which research cannot properly serve its intended purpose Dr Smith considers that there will be no radical change in the technique of carbonization either in the coking or gas industries for some time although a steady evolutionary advance will be made in matters of detail He considers that the future tendency of the carbonizing industries will be towards increasing flexibility, and pointed out that an all gas policy does not make for overall efficiency He prefers that flexibility which is derived from a variety of products, and as one example in gas manufacture pointed out that the yield of coke for sale could be increased by as much as 143 per cent if coal gas were used for retort heating so as to liberate coke for sale This very great potential increase in the production of coke has seldom been realized

As regards the relations of the two industries, it is obvious that even closer co operation should be brought about in order to utilize properly the coke-producing capacity of coke oven plants, when metallurgical coke is not being made, and the capacity in the gas industry, and also to overcome the difficulty of discontinuity in the supply of coke oven gas to other industries

The paper by Dr J G King struck an entirely different note Pointing out that the properties of coals are still not fully known, the author gave a variety of examples to show where a greater knowledge of these properties may not only influence the preparation of coal for the market and its use in existing industries, but may also indicate new markets. Thus a study of the physical structure of coal can give assistance in coal mining and coal breaking problems, in the dedusting of fine coal and in coal cleaning. It has already been shown that the nature and extent of the bands, partings and cracks in lump coal can be examined radiographically before and after the adsorption of lead salts, and that a study of microstructure can aid in the selection of coals for the production of active carbons in which the original structure of the coal is retained.

Dr. King pointed out the importance of the changes which occur in coal on heating, to the carbonization and other industries, and admitted that we are still very ignorant of the true meaning of these changes. A greater knowledge, he said, would greatly help coal blending and the precise selection of coals for special purposes such as complete gasification and the motor lorry gas producer. Although research on the chemical constitution of coal has not yet achieved its object, Dr. King feels that new lines of attack should be tried; previous work has already indicated new processes such as the production of ash-free coke by the Pott Broche process and the production of base exchange agents by the action of sulphuric acid. The paper stimulated a lively discussion in which many and diverse points were touched upon. It seemed to be generally agreed that the proper utilization of coals would be furthered by the close definition of their fundamental properties.

The paper sponsored by Prof. A. C. G. Egerton detailed one important aspect of the properties of coal, namely the part played by its sulphur content. Since the utilization of high sulphur coals may be one of our future problems, it is desirable to know now how the sulphur can be controlled. Mr. Armstrong (research student from South Africa) detailed experiments on the partial elimination of sulphur from coke by passing various gases through the coal during carbonization in the presence of inorganic substances. The reductions are quite marked in some cases with steam, hydrogen or ammonia; but inert gases have little effect.

The sulphur problem attracted some discussion from the steel technologists present, it being pointed out that a decrease of 0.1 per cent in the sulphur of coke would represent a saving of 1*s.* per ton in the cost of pig iron.

On account of the high cost involved, the production of motor spirit and oil from coal has not greatly increased in Great Britain, but considerable strides have been made in the technical sphere. Dr. R. Holroyd described some of the important advances which Imperial Chemical Industries Ltd. have made in connexion with the control of the chemical composition and octane number of the motor spirit. Three types of catalyst are now available for the vapour phase stage of the process so that cracking, hydrogenation and isomerization reactions can be controlled to give motor spirit of the composition necessary for high knock rating. Thus spirit can be made with a very high aromatic and low normal paraffin content; this has a high octane number (80) but a low susceptibility to lead tetraethyl (4 ml. per gall. raises the octane number to 86–7). Alternatively, spirit rich in branched-chain paraffins and low boiling naphthenes can be made; this has a lower octane number (75–6) but a much higher susceptibility to lead tetraethyl, since 4 ml. per gallon raises the octane number to 89–90. Dr. Holroyd said that when similar control has been established over the liquid phase stage the hydrogenation process will have more control over its products than the oil industry.

Although not the last paper of the evening Captain J. G. Bennett's paper really constituted a final word on coal utilization. By assessing the items influenced by the type of fuel such as overheads, maintenances, repairs, etc., he was able to demonstrate mathematical relationships between the "figures of merit" for fuels, these figures of merit being technical efficiency, economic efficiency and psychological merit. For the three types of energy, coal, gas and electricity a ternary diagram may be constructed. Although his proposals are still not fully developed, Captain Bennett was able to show how this diagram can be used for the analysis of statistical and operating data referring to fuel problems; the trends in costs can be followed and the appropriate fuel chosen for any particular purpose. The proposals attracted considerable interest, although it was thought that the large number of variables would make the calculation difficult and might impair accuracy.

Scientific Research and Industrial Needs in Canada

IN a recent address to the Canadian Chamber of Commerce, Major General A. G. L. McNaughton dealt with those activities of the National Research Council that serve to enlarge the demands of industry for the produce of farms, fields and factories. At present, Canadian industry draws about 12 per cent by value of its raw materials from agriculture, or about one third, if forests be included. He referred to recent progress in the United States, where four large research institutes, each endowed with an annual revenue of a million dollars, have been established; and he laid special stress upon German progress in the same direction under the four-year plan. Whereas about 45 per cent of the annual cut of wood was formerly used for low-grade fuel, now 95 per cent is consumed by industry, and Germany is striving to replace iron and steel for construction work by synthetic resins derived from wood and agricultural products. If Canada is to survive, said General McNaughton, she must follow the same path, for the old-time one product system of farming is becoming unremunerative in view of the growth of national self-sufficiency in Europe.

At the same meeting, Dr. C. Y. Hopkins outlined some of the chemical problems now being studied in Canada with the above object in view. China wood oil has of late been replacing linseed oil in varnishes and enamels, and the production of flax-seed in Canada has much diminished; hence efforts are being made to find a satisfactory alternative either by chemical modification of China wood oil or by breeding a new variety of oil-seed that could be cultivated in Canada. A home-grown substitute for the vegetable oils now largely imported for soap-making is also being sought Among the *faits accomplis* of Canadian chemists may be mentioned standardization of tests for honey, improved maple products, a method of drying apples and other fruits with better retention of flavour, and a wax mixture for use in plucking poultry

Dr. N H Grace dealt with projects and achievements in the field of biology Growth promoting substances are now added to the dusts used for disinfecting seeds The development of rust resistant varieties of wheat is estimated to have saved the prairie provinces about 38 million dollars this year Research is proceeding on the factors that determine the malting quality of barley with the view of growing more barley of better quality In 1937, some 80,000 tons of bacon were sent to Britain, prepared in twenty-six plants, each using its own method, research is now being directed towards improving both quality and uniformity

Methods have been developed for altering the heritable characters of plants by heat and chemical treatment, and progress in producing a drought resisting and soil binding forage crop for western Canada has been effected by crossing a Russian grass with the best Canadian wheat varieties From poplars and conifers it is hoped to produce, by crossing, rapid growing varieties of trees possessing hybrid vigour and disease resistance that may be vegetatively propagated with the aid of 'plant hormones

Admiralty Laboratories at Sheffield

THE new Admiralty Laboratories at Janson Street Sheffield, were opened on December 15 by Sir William Bragg president of the Royal Society

These laboratories, which have been constructed to cope with the ever increasing amount of Government work, are designed in such a fashion as to incorporate all recent developments in laboratory architecture The two large analytical laboratories, for ferrous and non ferrous analysis respectively, embody many unusual features One was struck with the arrangements which have been made for the conducting of chemical analysis on a large scale indeed the expression 'mass production might be used with respect to the systematizing of analytical methods certain benches, for example, being given up solely to determinations of one particular element The carbon combustion room was particularly intriguing in its lay out containing several combustion apparatus all set in a line and arranged for rapid analysis of carbon in steel A particular feature is made of spectrographical analysis, for which purpose Hilger quartz spectrographs are used This method of analysis has been brought to a high state of efficiency, and complete reliance can be placed on the results obtained

One was particularly impressed not only by the orderly and systematic arrangement of plant and apparatus, but also by the system with which the work is carried out, even the chemical store is a model of order and forethought The heat treatment laboratory, containing Birlec and Wild Barfield high temperature furnaces with temperature control devices, supplies all that is required for experimental heat treatment purposes, and it is understood that a high frequency furnace is shortly to be installed One of the most pleasing features is the lighting, the lower half of the windows being of Thermolux glass, which provides insulation from both heat and from the glare of the sun, whilst the walls of the laboratories are of a very pleasing tone of semi glazed fireclay tiles The air-conditioning system is novel, and no signs of fumes can be detected anywhere in the laboratories

These new laboratories are capable of turning out all the work that is necessary, and their constructional arrangement has considerably speeded up the rate of analysis They are most pleasing premises to work in, and those in authority are to be congratulated on this new development, which is significant of the scientific progress in metallurgical work for which the Admiralty has been responsible in the past

J H A

British Institute of Radiology

Annual Congress

THE twelfth Annual Congress of the British Institute of Radiology was held in the Central Hall, Westminster on December 7–9, and in connexion with the Congress there was an exhibition of apparatus organized by the British X ray industry The Congress was opened by the president, Mr W E Schall, the opening address being followed by the nineteenth Mackenzie Davidson Memorial Lecture, delivered by Dr G Shearer on "X rays—Their Influence in Pure and Applied Science' In the course of this lecture, Dr Shearer noted that twenty five years have elapsed since Moseley first observed the regularities in the *K* and *L* X ray spectra of the elements which pointed to the general similarities in the internal structures of various atoms and led ultimately to a fairly complete understanding of atomic structure and to the placing of electrons in their appropriate energy levels This same series of observations has also led to the use of X rays in the study of the solid state, with results of great practical and industrial importance From the study of simple crystals by W H and W L Bragg, the work has advanced to such an extent that complex molecules such as the proteins can now be studied, and the results, incidentally, linked up with the work of the organic chemists Another phase of X ray work entailed the study of materials from an industrial point of view, and in many cases the physical properties of materials can be correlated with the size and perfection of the individual crystalline components, while the X-ray method is the method of choice in investigations into the phase relations in alloy systems.

The physical papers dealt with certain lesser-known uses of radiations. F. I. G. Rawlins gave a paper on "X-rays in the Study of Pictures", dealing with the work carried out, largely at the National Gallery, on the X-ray study of the works of various old masters. He showed how, using radiation excited at very low kilovoltages (about 10 kv.), the lower structures of paintings could be revealed and the existence of alterations and restorations detected. In many cases, such studies have served to verify the traditional histories of the pictures. Dr. F. G. Fraser outlined the X-ray work of the British Museum (Natural History) in his paper on "Radiography in Zoological Research". He pointed out how the complete study of the skeletal structures of specimens too rare to be subjected to ordinary anatomical dissection was often helpful in placing animals in their correct zoological classifications.

A different type of investigation was considered by L. G. Nickolls in his paper on "The Use of Invisible Radiation in Police Work". This was mainly concerned with the use of ultra-violet and infra-red radiations in the detection of forgeries and overprinting in documents and identifying the positions of various stains on materials. As regards forgeries, etc., Mr. Nickolls pointed out that, from the point of view of criminal detection, it is important not only to establish the presence of alterations but also to read the words which have been erased. In order to do this, it is important to photograph the document in such a way that the background disappears. This can often be done by means of light in various selected wave-lengths, and certain bands in the ultra-violet region have proved of great use. Similarly, infra-red radiation serves to reveal marks embodded in the lower fibres of paper. As special cases, examples of frauds connected with motor-car licences and with stamps were given. The characteristic fluorescence of practically all physiological fluids under ultra-violet light sometimes served to identify their presence, but more usually fluoroscopic examination is used to reduce the areas to be examined by the more chemical methods.

Science News a Century Ago

Royal Astronomical Society

At the December 1838 meeting of the Royal Astronomical Society, several communications were made. The first of these was an extract of a letter from Bessel to Sir John Herschel alluding principally to the means which he had employed to ascertain the effect of temperature upon measurements made with the heliometer, which consisted in observing such of the stars in the Pleiades as were visible in the coldest winter, by night, and in the warmest summer, by day. "At the approaching disappearance of Saturn's ring", he also wrote, "sufficiently powerful telescopes will probably show *all* the satellites of the planet. I believe that large reflecting telescopes will begin to supersede achromatic ones; at least, I have no doubt they are capable of greater perfection. They *can* be made with mathematical precision, which is not the case with achromatic telescopes. I think also that opticians would have devoted their attention to them in preference, if they had not been discouraged by their more rapid destructibility. If the method of making an indestructible *metallic* surface could be discovered, I should no longer doubt of a still further perfection of the reflecting telescope. Could not *hard* steel be made available? and would it not, if proper care was taken of it, be less destructible than the common metallic reflector?"

The other communications included one by the Rev. R. Main on "Errors of Heliocentric Longitude and Ecliptic Polar Distance of the Planet Venus"; another from Airy, the Astronomer Royal, "A Catalogue of 726 Stars reduced to the Year 1830, and deduced from the Observations made at Cambridge in the years 1828–35"; an extract from a letter from Henderson to Baily relative to the eclipse of the sun on May 15, 1836; and also an extract from a letter of Lassell to Sheepshanks relative to observations made with a small sextant. The instrument was of only 3 in. in radius and was by Dollond. Lassell had made observations on various stars for time and latitude for the express purpose of determining how near to the truth he might be able to approximate by its means. He found that in ordinary circumstances, the mean of one set of altitudes east and another west, would give the time truly within one second, and that a set of each north and south, at something like equal altitudes, would give the latitude within eight or ten seconds.

Armstrong's Improved Water Wheel

William George Armstrong, afterwards Lord Armstrong, who was born in 1810 and died in 1900, was trained as a lawyer, and it was not until 1847 that he joined the small firm which was developed into the famous Elswick Works. Armstrong first obtained success as a maker of hydraulic machinery.

Armstrong's attention had been directed to the use of water-power in 1838, and the *Mechanics' Magazine* for December 29 of that year contained a contribution from him entitled "On Hydraulic Power". In this he referred to the limitations of the overshot water-wheel and the need for an appliance for utilizing the head of water from streams in hilly districts. The first step he considered necessary was to confine the water within a pipe. It was, he said, extremely important that the motion of the water through the pipe should be slow, "otherwise much of the force of gravity would be expended in the production of motion, and the power exerted in the machinery would in consequence be greatly diminished" He had heard that machinery with cylinders and pistons had been used, but to these there were objections. He then described and illustrated an apparatus suitable for the purpose. In this the water flowed through a tube formed into a semicircle. The inside circumference of the semicircle was slotted. A horizontal axis carried a wheel with an edge rim which revolved in this slot. The edge rim of the wheel had four circular apertures, fitted with disks, which would just pass through the pipes. The water acting in turn on these disks caused the wheel to revolve. Curiously enough, Armstrong did not mention the use of the hydraulic turbine of Fourneyron.

The Land in Colonial Development

POSTERITY will judge the success of tropical colonization by the condition of the land at the end of the colonizing period The fire of presently burning political, social and racial questions will be consumed in the fog of history, but the land will retain for all time marks of the treatment it receives There is little in treatment of land that is likely ever to become front-page news: colonial politics that get into newspapers are mainly concerned with the rights of the people living on the soil or rights to the minerals beneath it The public does not hear much of the rights of the soil. Hence the indication that at least one important section of officialdom recognizes, and encourages, the recognition of these paramount rights is significant Evidence that this fundamentally sound point of view is gaining ground is furnished by a recent report of the Conference of Colonial Directors of Agriculture*

The personnel of the Conference was not confined to directors and deputy directors of agriculture. Practically every British Dependency was authoritatively represented, and the meetings were also attended, by invitation, by a representative of the Union of South Africa, by officers of the Imperial Agricultural Bureaux and by leading authorities on agriculture, forestry and medicine in Great Britain. The subjects discussed by this very representative assembly of administrators and men of science included soil conservation, animal husbandry, nutrition, land settlement, produce inspection, agricultural education, and publicity.

The territories concerned are located in the tropics, where an early consequence of European colonization has been, almost without exception, to exhaust the soil, often beyond the limit of safety which the stability of the soil demands The stage of rapid exploitation has been followed, at least in British Africa, by an attempt to construct a type of society in which native interests would be accommodated within a framework of European civilization. We may say that this stage has been marked by a concentration on securing and adjusting the rights of both Europeans and natives and by an almost complete neglect of the rights of the land, which is now very insistently demanding prior consideration A striking feature of the report of the Conference is the repeated emphasis laid by the Colonial delegates on this need for placing the land first in formulating agricultural policy. No attempt was made to formulate a policy at the Conference, the object of which was rather to obtain expressions of opinions for discussion A policy, indeed, is not wanted so much as a balanced sense of what the land and the people require. Hitherto, the emphasis has been laid on human needs, now one can discern a tendency to emphasize the needs of the land. The pendulum, when it swings back once more, may settle down to an intermediate position of comparative stability

The widespread exhaustion and erosion of the soil are the clearest and most unmistakable signs that the land has hitherto been neglected in Colonial development. The Conference, therefore, gave soil conservation an early and prominent place in its discussions. Although the measures needed to counteract soil exhaustion and erosion vary considerably, it was unanimously agreed that the keynote of all conservation programmes is co-operation—between agricultural, forestry, veterinary, medical, educational, railway and public-works departments: in short, a readjustment of social conditions to conform more closely with the properties of the land.

---

* Report and Proceedings of the Conference of Colonial Directors of Agriculture held at the Colonial Office, July 1938 (Colonial No 156, 1938) (London H M Stationery Office, 1938) 2s 0d net

The essence of soil conservation is the establishment of a permanent symbiotic relationship between men and the land, to replace the symbiosis between plants and the land that has been disturbed by human settlement. It is becoming clear that domesticated animals must form a link between men and soil, if the desired symbiosis is to be achieved. A combination of animal and crop husbandry ties the farmer permanently to the land, and it is this tie, rather than the provision of manure and the diversification of crops, that constitutes the greatest value of mixed farming. At present, in many tropical countries serious erosion is being caused by overstocking, elsewhere soil exhaustion has been the result of too few animals being kept. The Conference expressed complete unanimity on the value of mixed farming in tropical agriculture, while recognizing the immense economic and psychological difficulties that its general adoption would involve

Directly linked with the question of introducing mixed farming is that of improving human and animal nutrition Most Colonial administrators realize the desirability of increasing the amount of protein and protective foods in the native dietary—an objective which could be attained by the general adoption of mixed farming, vegetable gardening and concentration on self-sufficient rather than export agriculture. Equally, the basic question of conditions of land tenure is very closely connected with that of soil exhaustion, but cannot be determined without reference to the type of husbandry that will finally become a permanent part of the life of the community. Mixed farming encourages long-term tenure; annual-crop farming encourages short-term tenure in temperate, and presumably also tropical, countries Memoranda presented by several Governments pointed to a close connexion between short-term leases, insecurity of tenure and the prevalence of erosion The report leaves the impression that not only security of tenure but also the desire for secure tenure need to be generally increased in most tropical dependencies Neither the average native nor the European in the tropics seems to be imbued with that innate love of, and pride in, the land which is the bedrock of European civilization Methods of education and propaganda that were discussed at the close of the Conference are directed towards inculcating into the natives a fuller understanding of the attitude the Europeans would like them to adopt towards their land.

Until we come to this final discussion, the impression may well be formed that the reform of tropical agriculture requires only a good start at any of the key points—soil conservation, mixed farming, nutrition—and it will complete itself in the development of a stable social structure which would accommodate both black and white. But the psychological link in the chain seems weak There is more hope than evidence that the average native will easily settle down to the mode of life demanded by mixed farming There seem, however, to be firm grounds for believing that tropical soils would be permanently improved by mixed farming, and could then be made to support a modified form of civilization without danger of soil exhaustion.

"Water, Water, Everywhere"

Theoretical Hydrodynamics
By Prof L. M. Milne-Thomson. Pp. xxii + 552 + 4 plates. (London: Macmillan and Co., Ltd., 1938.) 31*s*. 6*d*. net.

THERE has been a flood of books on the theory of the motion of fluids within the past few years. Some are good and others are not so good. Seventy-nine years ago, Besant published his "Treatise on Hydromechanics" in one volume, and in Great Britain the book remained as the authority on the subject for twenty years. Then in 1879 Lamb published his "Treatise on the Mathematical Theory of the Motion of Fluids", and in 1888 Basset produced his two volumes on "Hydrodynamics". The subject kept on growing, and in 1912 Ramsey, after having spent eight years on the project, published his "Hydrodynamics". By this time Lamb had brought out three successively enlarged editions of his book, renaming it "Hydrodynamics", and was more than half-way through a revision of the subject prior to bringing out a fourth edition. So the race went on, and the problem was how to keep abreast of research, research which was altering vitally general ideas on the subject. By 1932 Lamb had passed through six editions and was universally recognized as *the* authority. Ramsey's book was generally accepted as the most useful introduction to Lamb, and in 1935 it appeared in its fourth enlarged edition.

The books referred to above are capable of being used as text-books for teaching purposes In addition, many manuals of terrifying size have been published from time to time, notably by Germans and Americans. These manuals will all, I think, be superseded by a really excellent two-volume publication which has just appeared under the title of "Modern Developments in Fluid Dynamics". It is a composite work published by the Fluid Motion Panel of the Aeronautical Research Committee of Great Britain under the general editorship of Dr S Goldstein

The mathematical discipline used in classical hydrodynamics has been employed in aerodynamics, tidal theory, meteorology, geophysics, classical electrical theory, and elasticity There have been great changes in some of these subjects within living memory, but none so great, perhaps, as in aerodynamics, and to a large extent nowadays, research in hydrodynamics means research in some problem connected with aeroplanes The great change was brought about by people with a sound knowledge of practical problems who jumped over questions of mathematical rigour on the wings of 'the intelligent guess'. Prandtl, G. I. Taylor, Reynolds, Lanchester, Kármán are some of the names which spring to mind in this connexion The dissatisfaction with the limitations imposed by the mathematically rigorous methods of classical hydrodynamics was made quite clear by the interest aroused in 1926 on the publication of Glauert's little book "The Elements of Aerofoil and Airscrew Theory" It was, and still is, an excellent introduction to more recent investigations. Within a few years of its publication, it was translated into German, the language in which many of the researches it described first saw the light of day.

Since then many books have been published—American, French, German, English—each with its special contribution to knowledge, but it is extremely doubtful whether any of them show the highly developed powers of criticism and discrimination seen in Lamb, Ramsey and Glauert. Prof. Milne-Thomson's book, now under notice, is another of these. It, too, makes a contribution—a mathematical one. It is an excellent collection of worked examples in the style of the classical hydrodynamics, but with two exceptions. These are, first, the systematic use of vector notation, and, secondly, the insertion of many intermediate steps when a problem is worked out. The first of these differences is not likely to endear the book to engineers, but the second most definitel will.

Several sections and features of the book ar worthy of favourable notice The lavish use o simple diagrams is an excellent feature These diagrams and the many lines of mathematical symbols help to break up the text and give the pages an 'open' appearance as compared with the cramped look on the pages of many manuals where the words seem to crowd together in order to avoid taking up too much room Chapter ii on vectors is particularly useful as a concise summary of that part of the subject which is required in the study of hydrodynamics Similar remarks can be made of Chapter v on complex variable theory. From the point of view of physics, Chapter i is noteworthy for the simplicity of its style and for the fact that fairly complicated results are obtained extremely elegantly. The whole book is in fact remarkable for the clarity of its exposition

One major criticism that can be offered is connected with the plan on which the book is constructed Undue emphasis seems to be laid on subjects which from the present point of view are trivial. Chapter xi, dealing with the theory of discontinuous fluid motion, could be drastically curtailed if only for the fact that the theory does not give results which agree with experiment The subject is interesting historically, and nothing more Similarly, a wrong impression is given if, as in Chapter xii, the subject of "Wakes" is treated as if it were a branch of discontinuous flow. Mathematical results can be obtained and problems can be solved, but it is doubtful whether the results are of any value. The importance of "Vortices" is well recognized in Chapters xiii and xviii, but "Waves" receive insufficient treatment in Chapter xiv. Lamb devotes about 300 out of his 700 pages to waves, but in this book only 50 out of about 550 pages are given to the subject It is only in the last chapter—that on "Viscosity"—that one approaches the real problems of the present day.

There are a number of points of minor importance which might receive the author's attention in subsequent editions of the book First, no table of "Historical Notes" on theoretical hydrodynamics is complete without some reference to Prandtl, Lanchester, G. I Taylor, Kármán, Lagrange, Laplace, Cauchy and Poisson. Secondly, the footnotes, though few in number, should be drastically revised. It is surely unnecessary to define the meaning of $\underset{t\to t_1}{\text{"Lim"}}$ and "infinity" in footnotes—even if a previous knowledge of only the elements of infinitesimal calculus is assumed by the author. It is surely unnecessary too, to give a footnote to "Lewis Carroll" and a place in the index, because he used the word "burble" in Jabberwocky. The word can also be found in the Concise Oxford Dictionary! More references to Prandtl (who receives two), G. I. Taylor (who receives one) and Lanchester (who receives none) in the index of a book on theoretical hydrodynamics would not be out of place. There are a number of points of similar order of importance dealing with the text, but one does not wish to dilate upon them lest the impression be conveyed that the defects outweigh the many important qualities of the book

The 508 examples which are included in the book lead one to assume that Prof. Milne-Thomson intends the book to be used for teaching purposes. Unfortunately, the price is prohibitive so far as most students are concerned. The book, however, is a valuable asset in any library, as it indicates clearly and fully what has been done and what can be done by classical processes and by vector notation It is to be hoped that some day Prof. Milne-Thomson will turn his attention to more modern theories, and will give us as clear an exposition of them as he has of the foundations of the subject.

L. ROSENHEAD.

Exploring for Plants

The World was my Garden:
Travels of a Plant Explorer. By David Fairchild, assisted by Elizabeth and Alfred Kay Pp xiv + 494 + 129 plates (New York and London . Charles Scribner's Sons, 1938) 18*s*. net

THIS book is the autobiography of David Fairchild, written with the assistance of Elizabeth and Alfred Kay It consists of an account of his life and of his varied experiences during the course of his journeyings as a plant explorer In early manhood, Fairchild's chief interests were in the direction of plant pathology, and it was not until 1895, when he met his friend and benefactor, Barbour Lathrop, that he began to concentrate on the problems of plant introduction For the next twenty years, he travelled continuously all over the world collecting plants, particularly those of economic importance, and dispatching them to his native country He finally became head of the Division of Foreign Plant Exploration and Introduction of the U.S. Department of Agriculture, and retired in 1935

The last quarter of the nineteenth century was the golden age of the plant collector. World communications had already developed considerably, but vast new areas had only just been explored or were in the process of being put on the map. This state of affairs coincided with the great interest that was being taken in the application of science to agriculture, and Fairchild sized up the possibilities of the situation in a remarkable fashion, and made the most of his opportunities. Wherever he went he seems to have found, with comparatively little difficulty, types and varieties of cultivated crops and fruits that were either not established in, or were unknown to, the United States, and which if introduced would be of great value to the agriculturists and horticulturists of the New World.

A perusal of these pages will bring home to the reader what these opportunities were and the success that crowned Fairchild's efforts He journeyed without ceasing for many years and the record of his travels is almost kaleidoscopic in its effect on the reader He tells of trips to Iraq for new varieties of dates, to Egypt for staple cotton, to Western China for tung oil and to the Argentine for a hardy type of avocado. These are a few only of the many mentioned in this volume Much of the material was apparently picked up with comparatively little effort, for in those days the field was almost a virgin one. Later in life, he was able to consolidate his earlier work by establishing acclimatization stations in the United States.

The narrative is a long one and so packed with incidents that at times it is somewhat difficult to digest all the matter contained. It is written for the lay reader, and incidents that occurred during the various expeditions give one an insight into the adventures and hardships that were incurred. It is not simply an account of plant exploration, for the narrator makes frequent diversions from the main topic in order to mention interviews with people famous in other realms of science and incidents of fundamental importance to the history of the world, such as the discovery of Röntgen rays or Glen Curtiss's flight in a heavier-than-air machine in July 1908.

The story is presented in a direct style and is lightened by touches of natural humour. There are occasional slips, as for example on p. 123, when the late Dr. J. B. Harrison is described as being the discoverer of sugar-cane seedlings. In Barbados and the West Indies generally, this honour has always been ascribed to the late John R. Bovell.

Dr. Fairchild is an expert with the camera, and the book is well illustrated with more than two hundred beautiful photographs covering the greater part of his journeyings.

Mathematical Analysis

(1) Analyse des courbes, surfaces et fonctions usuelles, intégrales simples

Tome 1. Par Paul Appell Cinquième édition entièrement refondue par Prof Georges Valiron Pp ix + 395. (Analyse mathématique à l'usage des Candidats au Certificat de mathématiques générales et aux Grandes Écoles, d'après les cours professés à l'École centrale des Arts et Manufactures et à la Sorbonne Cours de mathématiques générales) (Paris: Gauthier-Villars, 1937) 100 francs

(2) Variables Complexes

(3) Advanced Calculus

By Prof W Benjamin Fite Pp xii + 399. (New York The Macmillan Co, 1938) 21*s* net.

(4) Introduction mathématique aux théories quantiques

Par Gaston Julia Deuxième partie Pp vi + 218 (Cahiers Scientifiques Fas. 19) (Paris. Gauthier-Villars, 1938) 85 francs

(1) PROF APPELL'S work on mathematical analysis, of which this is the first volume, is a classic which has been appearing in successive editions since the year 1898, when it contained the substance of a course of lectures given by the author at the École Centrale des Arts et Manufactures in Paris

The present edition, sponsored by Prof. Valiron, contains all the analysis and geometry necessary for the Certificat des Mathématiques Générales at the Faculté des Sciences, and in spite of numerous modifications, additions and suppressions, conserves the spirit, if not the exact form, of the original work The book was not intended to be a treatise, far less an encyclopædia; but a course of studies proceeding consistently from the simple to the more complex. Thus, complex numbers are introduced at a late stage, so that once the student has grasped their nature, he can use and apply them at once. The geometrical introduction contained in the first three chapters is always given at the Sorbonne as a preliminary aid to the usual course in mechanics

(2) Prof. Buhl's extremely interesting monograph on the theory of complex variables, which forms the second volume of his treatise on the new elements of mathematical analysis, has as distinct a philosophical flavour as is possible for a work that is primarily a course of instruction. As in the preceding volume, the author is concerned with the presentation of mathematical ideas from the triple point of view of logic, geometry and physics, and he once more lays stress upon the duty of every professor of an advanced subject, not only to keep in contact with modern developments, but also to incorporate them so far as possible in his teaching

As Prof Buhl points out, the past twenty years have marked an epoch during which geometrical theory has been consistently and brilliantly applied to physical phenomena Although opposing schools still dispute the legitimacy of derivatives, he considers it essential to investigate the implications of functional theory in spite of the growing complexity of the task. The first chapter of the volume, therefore, is entirely devoted to functions, and is based on an initial theorem concerning even and uneven functions, which permits of generalization in the form of cyclic functions attached to roots of unity The functional point of view thus engendered reviews earlier considerations concerning periodic, elliptic and modular functions as well as modern quantic aspects A final chapter is dedicated to the work of Charles Hermite in theoretical physics.

The whole book is punctuated by remarks and criticisms which stimulate further investigation of the philosophical consequences of the theorems enunciated and a more intensive analysis of the meaning of terms and operators

(3) Prof. Fite's "Advanced Calculus" is intended as an introductory course in analysis for students who are seriously thinking of specializing in mathematics Although a preliminary course in the calculus as well as an ability to differentiate and integrate ordinary functions is assumed, the author is so convinced that no real progress in analysis can be made without a thorough understanding of these operations that he proceeds to define and explain them as lucidly as possible The real number system is discussed in the first chapter, for the benefit of those whose knowledge of it cannot be assumed. But a study of Lebesgue integration is left for the student who will continue later to specialize in the developments of analysis. Of the last two chapters, the one on the theory of functions of a complex variable will be very helpful to students who are not taking a course in the subject, while the other, albeit more specialized, in

which the calculus of variations is discussed, will provide the reader with a useful introduction to a very wide and important field.

(4) The second part of Prof Julia's mathematical introduction to quantic theories, of which the first part has been already reviewed in NATURE, is devoted to a study of Hilbert space in its various aspects—the subject of Section I—and an investigation of the linear operators of this space, which is the subject of Section II.

The geometrical investigation of Hilbert space is the result of a parallel examination of its two analytic aspects—the vectorial and the functional. These are to be found in Chapters i and ii and serve as a basis for an axiomatic definition of Hilbert space with which Chapter iii is concerned. But as Prof. Julia remarks, the order could quite well have been reversed by beginning with the axiomatic definition and deducing from it the vectorial and functional aspects.

In Section II, there is a detailed examination of the restricted linear operators of Hilbert space and their analytic representation by means of infinite matrices, together with the algebraic calculus of these operators and matrices. In particular, a study of the inversion of these restricted operators (and the resolution of linear systems in an infinite number of unknowns) has been developed so far as possible in geometric form. In paragraphs 3 and 4 of Chapter v, a number of demonstrations and propositions of a simple nature have been incorporated so as to show the geometric character of the correspondence established in Hilbert space by a restricted operator, notably in particular cases which form the basis of the theory of spectra, where this correspondence is not everywhere one–one. Prof Julia announces that a forthcoming monograph will deal with the analysis of the restricted linear operators and their spectra.

Social Organization in Bechuanaland

A Handbook of Tswana Law and Custom
Compiled for the Bechuanaland Protectorate Administration by Prof. I. Schapera. Pp. xiv + 326 + 1 map. (London: Oxford University Press, 1938) 21*s*. net

PROF. SCHAPERA'S "Handbook of Tswana Law and Custom" appears opportunely, at a moment when the future of the South African Protectorates is a matter of grave concern. It places before the people of South Africa and Great Britain a comprehensive view of the framework in law and custom of society among the native population of Bechuanaland, and at the same time gives them an opportunity of informing themselves of certain aspects of the conditions with which the administrative system has to cope in relation to native institutions. Moreover, it is significant that the inquiry, of which Prof. Schapera's handbook is the outcome, was undertaken, as Col. Rey, the former Resident Commissioner, points out in his preface, not only at the invitation of the administration, which was desirous that its officers should have for their guidance a carefully tested body of information, based upon scientific methods of inquiry, on native law and institutions, but also with the approval of the natives themselves. The older men of the tribes were disturbed, not only because a younger generation was growing up which was unacquainted with tradition and custom, but also because even among themselves there was much uncertainty as to the law They, therefore, expressed a strong desire that such a record as this should be made.

The task undertaken by Prof Schapera was by no means simple. The population of Bechuanaland is far from homogeneous Not merely has there been a long-continued process of fission and fusion among the tribes, such as is common to the history of most Bantu-speaking peoples, but also it includes Hottentot and Bushman, and it has received numerous accessions from outside its borders, both Bantu, from various sources, and Herero. Hence there is much variation in custom, which at times even appears within the same tribe, as, for example, in regard to marriage. Such problems, however, at this late date are too often a commonplace of anthropological investigation; but for this reason the author cautions the reader that the results of his inquiry in this volume apply specifically only to the Kgatla and Ngwato, who were under his direct observation, and that other tribes must be the subject of further investigation

The social organization of which Prof. Schapera has had to take account in considering the functioning of Tswana law and custom is relatively of an advanced type. At the head of the tribe stands the chief, not merely as its ruler and leader, but also, in a special sense, as the embodiment of the tribe as a whole. His powers are tempered, however, by his councils; while in relation to land he is the holder for the use of his people, rather than the absolute owner, a point on which there has been frequent misunderstanding in relation to tribal lands. The distinctive feature of this society is the delegation of control through a succession of subdivisions—section, ward and so forth down to the individual family—in each of which the headman controls the divisions and individuals below him in the social hierarchy. In the matter of the law, the chief is the interpreter and exponent, who applies traditional procedure to cases, rather than the law-giver, though that function may be assumed on occasion, as when Kgama came under the influence of the missionaries and promulgated laws on various matters of tribal practice. In view of the fact that until recently there was no written record of judgments, the distinction between law, even case law, and custom is not a matter of hard and fast rule, nor, perhaps, a matter of great significance

The aim of the administration has been to preserve the position and power of the chief, subject to certain reservations in matters in which freedom of action is considered incompatible with British control. These reservations, however, even though made with due deliberation, such as, for xample, in the restriction on inflicting the death penalty, are bound to affect the prestige of the chief Missionary influence, even though well-intentioned or well-informed, also plays its part in modifying the relation of chief and tribe, but the most serious among disturbing factors is the change in economic conditions. One example mentioned by Prof. Schapera is the evasion of the duty of performing work for communal benefit at the call of the chief, incumbent upon the regiments into which members of Tswana society, both male and female, are organized The rule of the *corvée* is broken by individuals, who thereby flout the authority of the chief, because they will not be paid, as they are when they work in the mines, or for Europeans.

Prof Schapera is careful to point out that his handbook is not a code That this should be clearly understood is essential The future of native Africa depends upon the recognition of the fact that its law and custom are not static and stereotyped, but that the principles upon which African society is based can and must be adapted to meet changing conditions, provided that the adaptive process is not allowed to become disruptive and that harmony with the soul of Africa is maintained

---

A Falconer in Iceland

In Search of the Gyr-Falcon:
an Account of a Trip to North-West Iceland By Ernest Lewis. With a Memoir of the Author Pp xxiii+235+24 plates. (London: Constable and Co., Ltd., 1938.) 12*s*. 6*d*. net.

IT is delightful to turn to this book by Ernest Lewis. It refreshes the reader after a spate of books, some of them second-rate and decadent, which are flooding the market at the present time. Let it be said that Ernest Lewis's book is produced in excellent taste, from the jacket to the last page The print is good, the photographs are well reproduced, the design of the jacket is unusually pleasing.

This book describes a journey recently made by "Ernest Lewis" (the pen-name which Ernest Vesey took to hide his identity). The author has unhappily not survived to see the success of his book and it is therefore fitting that, in a feeling foreword, his father should have disclosed to us the author's real name.

Ernest Vesey travelled to Iceland to bring home young Iceland falcons to be trained in falconry. He arrived alone in that northern country, knowing well the difficulty of his task. By sea he travelled from Reykjavik up to the north-west peninsula of Iceland, to a district that is little known even at the present day. He had been led to believe that the Iceland falcon even here was a rare bird, but by perseverance, handicapped as he was by the loss of an eye and an arm, he explored, sometimes on horseback but usually on foot, desolate glens and valleys, forded on foot rivers so swift and deep that once he was swept away in the icy current, braved perilous seas in small boats, scaled cliffs considered inaccessible, and at the end of all his journeyings found that the Iceland falcon was less rare than was supposed, and succeeded in bringing back a brood to Scotland.

The book is simply and graphically written, and an intense love of all living creatures stands out from its pages Whether the author is watching the king eider in all the beauty of his plumage, or the sea eagle sailing majestically past him, or the noble Iceland falcon rushing in to do battle with the eagle, Ernest Vesey shows himself to be not only a bird observer, true and faithful, but also a bird lover.

The hardships of Icelandic life, and the cold beauty of that country, are also brought vividly before the reader in this fine book.

SETON GORDON.

Hand- und Jahrbuch der chemischen Physik

Herausgegeben von A. Eucken und K. L. Wolf. (1) Band 9, Abschnitt 3 und 4: Anregung der Spektren, von W. Hanle; Molekülspektren von Lösungen und Flüssigkeiten, von G. Scheibe und W Frömel. Pp. 184+16. 18 gold marks (2) Band 9, Abschnitt 5: Kernspektren. Von K. Philipp. Pp. xi+185–283+17–22. 11.20 gold marks. (3) Band 8: Abschnitt 2. Lichtzerstreuung. Von H. A. Stuart und H.-G. Trieschmann. Pp. ix+191+20 24 gold marks.

Leipzig: Akademische Verlagsgesellschaft m.b H., 1936, 1937.

THESE sections of the "Hand- und Jahrbuch der Chemischen Physik", like their predecessors, are noteworthy for their completeness, good presentation of experimental facts and technique, and their convenient format. It is impossible here to do more than comment upon a few of their more striking features.

(1) Hanle's discussion of the methods of excitation of spectra is well arranged and easy to follow, and the reviewer particularly liked the manner in which potential curves are explained and introduced wherever necessary The section by Scheibe and Frömel on the spectra of liquids and solutions contains a neat outline of the methods for the measurement of extinction coefficients, and a good treatment of the factors which affect molecular absorption, as, for example, the effects of the solvent upon fine structure.

(2) Perhaps the section on nuclear spectra by Philipp is the one most likely to be sought out by English readers, on account of the rate at which development in this branch is proceeding. The author gives very complete accounts of long-range alpha particles and their fine structure. He gives a careful analysis of β-ray spectra and the theory of β-ray disintegration, and his concise treatment of γ-ray spectra, with the discussion of the time of emission of γ-rays from the nucleus and nuclear composition, is very pleasing to read.

(3) Finally, we come to the section on the scattering of light. Stuart deals excellently with phenomena in the visible spectrum and Trieschmann with the coherent scattering of X-rays. Perhaps it is permissible to suggest that it would be well if, in English books on scattering of very high frequency radiation, a clear distinction between coherent and incoherent scattering were always drawn.

L. F. B.

The Geographer's Protractor

Designed by Prof. F. Debenham. Ivorine, 6 in. × 2⅜ in, with 8-page Explanatory Booklet. (London: T. Murby and Co., 1938.) 6s.

THERE are several features of this new protractor that make it most acceptable. Made of ivorine encasing a metal reinforcement, it is strong and rigid and the scales and other markings stand out clearly and are unlikely to be obscured by usage. The width is half an inch more than usual, which gives greater accuracy than is obtainable with narrower instruments for angles near 90°. The edges are well bevelled. On the edges of the reverse side are scales for the principal maps of the Ordnance Survey, six inches, one inch, and half an inch to the mile. Scales are also given for the principal Continental scales (1 : 10,000; 1 : 20,000, 1 : 50,000, 1 : 100,000; 1 · 62,500; and 1 : 250,000). The six-inch scale has also a scale of chains. A gradient scale for the six-inch map should also be useful on many occasions. The usual diagonal scale of inches and a centimetre scale are provided. On the upper side there are some useful features in the scales for the direct plotting of map projections, the use of which should save the student much time All the more usual projections can thus be drawn directly.

It is in every way a most useful protractor and most pleasing to handle. Prof. Debenham is to be congratulated on his design.

Trigonometry

Part 1. Intermediate Trigonometry. By Prof T. M MacRobert and William Arthur. Pp. x+206 (London: Methuen and Co., Ltd, 1937) 5s 6d.

THIS attractive volume has been designed as the first part of a complete work on trigonometry and bears the sub-title, "Intermediate Trigonometry" It begins, however, with the definition and measurement of angles and proceeds quite logically and rigorously to the solution of triangles. Amongst the many commendable features of the book the following deserve mention

Circular measure is rightly introduced in the first chapter, and is developed from the fundamental theorems upon which it is based. The chapter on graphs is not only very clearly written but also is illustrated by a series of well-drawn curves, including those of the inverse functions. Then again, in order to render the proofs valid for angles of all magnitudes, the Addition Theorems are established by an application of the theory of orthogonal projection, a very lucid exposition of which is given in the previous chapter. Finally, quite a full and stimulating chapter on the properties of quadrilaterals concludes the course.

Motor Benzole:

its Production and Use. By W. H. Hoffert and G Claxton. Second edition. Pp. xxv+933+3 plates (London: National Benzole Association, Ltd., 1938) 42s. net.

THE subject covered by this book is of great importance and one which continues rapidly to develop, as is witnessed by the fact that the new edition contains 50 per cent more subject-matter. New chapters contain information relating to the production of aromatics from gaseous hydrocarbons: there are those who predict that much motor-fuel is to be made this way in the future, which may mean that the whole of our tar production may be first cracked to gas and this synthesized to antiknock petrol. If this became true, home-produced oil would be a fact at long last.

The Trawl Fisheries: A Scientific and National Problem

By Michael Graham, Fisheries Laboratory, Lowestoft[*]

IT is common knowledge that the trawl fisheries have mainly been unprofitable for many years and that the number of British fishermen has been reduced by about thirty per cent since 1919 Some of this decline is due to loss of herring fishermen , and this article is not concerned with that section of the industry. Part of the reduction is due to loss of trawler hands and inshore fishermen and, so far as these sections of the industry are concerned, recent scientific work has a very practical bearing, and leads to a comprehensive statement on the conditions under which the industry can be permanently profitable or unprofitable

A selected list of literature on the subject would consist of references to Baranov (1916), Moek (1930), Russell (1931), Hjort, Jahn and Ottestad (1933), Thompson and Bell (1934), and Graham (1935), so that, except for Baranov's paper, which was unfortunately overlooked, we have had a scientific development of recent date, and from such widely separated places as Oslo and Seattle The present article does not attempt to give the details, but only to illustrate the modern development of the overfishing problem and its wide implications. Data will not be used except in one illustration, because they are *statistical* and therefore cumbersome, but it must not for that reason be thought that the solutions are only theoretical On the contrary, for the North Sea, three mainly independent lines of evidence have been used, and one of these, that of general statistics, is available for many other areas

Perhaps the most important fundamental conception in the problem is that of 'principal' and 'interest' of the stocks of fish. Stocks tend to grow in weight by reproduction (A) and by the increase of weight of individuals (G) They lose weight by natural mortality (M) and their 'natural' increase is

$$A + G - M \qquad . \quad . \quad . \quad (1)$$

the addition and subtraction being justifiable if all these processes are measured in a certain way. Mathematical considerations, such as this one, may conveniently be accepted in this article without explanation. The introduction to a recent paper[†] has attempted to explain the necessary mathematics 'without tears'.

Expression (1) is the 'interest' of the stock, and if fishing is no more nor less than this, the stock will be unchanged in weight Fishing, however, often takes more than this 'interest', and the weight of the stock is then reduced. So long as the fishery is profitable, this reduction of stock causes no inconvenience to the industry, and science is not called to make any suggestions for regulation Nor has the modern scientific statement anything useful to say about this consumption of 'principal' in itself At that stage, the situation has no element of permanency It is, however, in the matter of the 'interest' at different levels of 'principal' that the modern methods have, been able to draw conclusions, and that is, in fact, the problem we are required to answer—how to make the industry permanently profitable. This cannot be done as regards any particular year, because of fluctuations in stocks of fish and of markets , but the aim is to make the industry permanently profitable on the average, if such a state may be called "permanent"

The scientific problem is, therefore, what happens to

$$A + G - M$$

at different levels of stock, excluding fluctuations ?

The three known approaches to the problem may now be illustrated.

I. General Statistics

An example, from an area that is generally thought not to be overfished, is given by the fisheries for haddock and plaice at Iceland in recent years. A natural increase in the stock of cod, called by Kemp (1938) a "long-period fluctuation", has caused fishermen, of whom the British fishermen must be taken as representative, to double their effort in this area (Fig. 1) The number of hours fishing per annum rose by about eighty per cent between 1925 and 1931, and new and fast vessels with more deadly trawls were introduced during that period. At first, haddock, and, to a less extent, plaice were taken in increased quantity, but the permanent result was to lower the yields of both species to levels in 1933–1935 which they have never reached before in any three peace-time years since 1906, when these international statistics were first collected.

The difficulty of this evidence is that it does not distinguish between 'principal' and 'interest'.

---

[*] Based on a paper "Rational Exploitation of the Fisheries" read before Section D (Zoology) of the British Association at Cambridge August 19.

[†] Graham (1935). We use logarithmical rates.

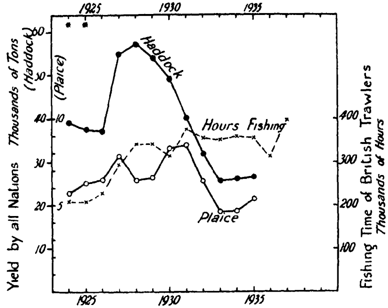

FIG. 1

However, statistics of landing per hundred hours fishing of the category 'large' show that the yields of 1933–1935 represent 'interest', there being no trend in the density of these older fish. The yields in the period before 1926 seem to have been mainly but not entirely 'interest' at a higher level of stock.

The conclusion is that this increase in expense of fishing is mainly wasted, if not worse, for these two species.

2. ESTIMATES OF RECRUITMENT, GROWTH AND MORTALITY

In fishery investigations, the rate of recruitment (A) is given by the percentage by weight of the youngest age-group observed in a census of the fishable stock, the age being determined by reading the scales or some other method There is a theoretical difficulty, which should not be forgotten, in that recruits may come in in older groups also.

G, the growth-rate, and Z, the rate of total mortality including fishing, are obtained from the same material. C, the rate of capture or fishing, is obtainable from marking experiments (Graham, 1938). If Z and C are correctly measured, then natural mortality is given by

$$M = Z - C \quad . \quad . \qquad \text{(ii)}$$

The yield, Y, is given by either

$$S(A + G - M) \text{ or } SC \; . \quad \text{(iii)},$$

whichever happens to be more convenient, where S is the weight of stock. So far, we have only been interested in the ratio Y_1/Y_2, so that absolute values of S are not required

The calculation of Y_1/Y_2, with different rates of fishing, and therefore of Z, assume a, g and m unchanged, the small letters indicating rates for particular ages. This is demonstrably justifiable for small changes of rate of fishing, in a heavily fished stock, and the information derived is at least reliable as to whether a stock is overfished or underfished It is not, however, justifiable to use this method for calculations involving large changes in rate of fishing and density of stock

Estimates of relative yield with different rates of fishing, and therefore of Z, have been made on these lines, for Pacific halibut and for cod, haddock and plaice of the North Sea In the last-named three fish the calculations had a peculiarly

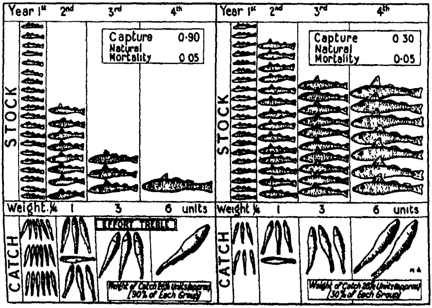

FIG. 2.

difficult form, because the data only gave the order of magnitude of the rate of natural mortality, not any more precise estimates.

An illustration of an imaginary case is given in Fig 2. Very high and very low rates of fishing are illustrated, for which large differences, as we have seen, the real calculations are not justifiable. Also the population under a low rate has been assumed to suffer sudden extinction after the fourth year, so as to keep the drawing a reasonable size The diagram is self-explanatory. It is seen that the weight of the catch can easily be the same under a low rate of fishing as under a high rate

If, now, the trawl catches thirty per cent of the fish on the strip of ground over which it is dragged, then, assuming constant replenishment, the area inhabited by these fish would have to be towed over three times in a year to give a rate of fishing of ninety per cent. But towing over the area once only would give the rate of thirty per cent and the same yield Clearly there is room here for a large cut in the expenses of fishing.

(The number of survivors in each group of, for example, the left-hand side of the diagram, is calculated by the formula $n_1e^{-it} = n_2$).

3. THE SIGMOID CURVE AND PRACTICAL IMPLICATIONS

We have seen that, however clear it may already be that fishing can be, and is, wasteful of effort, by overfishing, any estimate of the best yield and the best rate of fishing, over the whole possible range, requires experience of different rates of fishing and a theory as to how the rates of recruitment, growth and natural mortality vary with different densities of stock. A first solution of this problem has been reached for the demersal fishes of the North Sea taken together, cod plus haddock plus plaice, etc, taking into consideration the various effects of partial reduction of fishing during the war of 1914–1918.

The theory depends on two assumptions.

A. There is a limit to the weight of stock which an area will support.

B. The rate of natural increase, V, ($= A + G - M$), is directly proportional to the difference between the weight of the stock at the moment and the maximum weight the area will support. The assumption of direct proportion is only a first approximation.

With these two assumptions it will be found (graphically is an easy way to do it), that the weight of a stock growing in an empty area will follow the well-known S-shaped curve of the 'logistic' function, that has been used by Pearl and others to express the growth of populations* (Fig. 3, S).

The curve of Fig. 3 will now be used to show the practical implications of the modern statement, although it will become obvious that these implications could reasonably, but less neatly, be derived from the conclusions of general statistics or of fishery investigations (1 and 2 above)

When a fishery begins in an untouched area, the stock is represented by some high point such as S_a in Fig. 3, where V equals zero, or nearly The fishery *must*, therefore, take 'principal' as well as 'interest' and deplete the stock, a process that has caused alarm in the past, alarm which appears now to have been premature If the depletion takes the stock to S_b, and stability is allowed, V can be read off from the scale on the left as

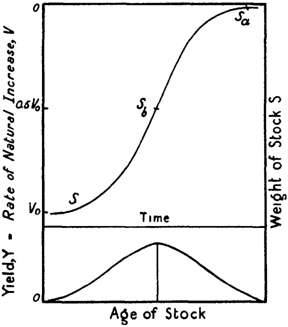

FIG 3.

$$0{\cdot}50\ V_0$$

If the fishermen were content to fish at this rate, the stock would remain at S_b and the yield would be

$$0{\cdot}50\ V_0S_b$$

But this expression is the rate, in absolute terms such as grams per annum, at which S would increase if left alone, that is, it is the differential coefficient of S at the point S_b.

Similarly, the yield at any level of stock is given by ordinates in a curve of differential coefficients, which can be plotted separately below the curve S.

As a fishery develops, the rate of fishing tends to increase, so long as there is any profit. Grounds and habits of fish become better and better known.

---

* See, for example, Reed and Pearl (1927).

Dangers to gear become more efficiently avoided. Inventors constantly try to make the gear more deadly. So the stock is driven down the *S*-shaped curve, until the ratio of effort to yield becomes so great as to be unprofitable. Here a sad equilibrium is established, with the fortunate few making a profit, most fishermen just covering expenses, but persisting in the hope of a favourable fluctuation, some making losses. So long as the rate of fishing is not deliberately held at a fixed level, this quagmire effectively holds the industry If anything, such as mesh regulations, marketing schemes or cheaper fuel, promises more profit, there is a tendency for the rate of fishing to rise. Banks are more willing to lend money, owners more willing to replace ships and gear, better men are more willing to become fishermen. But if the rate of fishing rises, the stock goes further down the *S*-shaped curve, to a less profitable level So the profit in a highly developed fishery is remarkably like the crock of gold at the foot of the rainbow.

If, however, the rate of fishing could be held at a fixed level, including fishing of all nations on a given stock, there is no reason why such measures should not be profitable.

There seems, however, to be a more fruitful source of profit in a definite reduction of the rate of fishing, for this, properly arranged, means reduction of the running expenses of fishing. It is on this, the expenses side of the balance sheet, that the modern statement expects the main profit For example, the first approximation estimates the maximum yield of demersal fish in the North Sea at fifteen per cent greater than the yield of recent years But the rate of fishing to give this yield is estimated as to be reduced by twenty-five per cent, which is a greater figure

An important technical difficulty is how the rate of fishing could be controlled, because size, speed, age and seaworthiness of vessels all affect the rate of fishing, as well as skill and zeal of the crew. Nevertheless, some sufficiently good limitation of the sum total of fishing power of all vessels together expended per annum, might be devised The difficulty might, in theory at any rate, be tackled by a different approach, namely by fixing quotas of each species for each area. Apart from these important details, the choice is theoretically open as to whether reduction is in *number* of men and ships working, or *time per annum* during which they work.

At the present time, the future course of the industry is uncertain and the decline in number of fishermen makes the problem one of concern outside the section of the population that is financially interested. Under a recent voluntary scheme, some of the trawlers are laid up and others are operating under restriction, for the sake of regulating their markets. This is 'rationalization' as ordinarily understood. But the case, as outlined in this article, is something quite different —in fact unique—for rationalization in this case should mean a particular double process, namely, saving expense and giving the fish time to reach an age where the total nett growth of the stock is greater

Chemical Research and Industry

DEPENDING upon the mood or the point of view, it is equally easy to be surprised at the large, or concerned at the small, impression which a single laboratory can make on the pile of industrial—even national—chemical problems awaiting solution. To read the report of the Chemistry Research Board and the report of the Director of Chemical Research for the triennial period 1935–1938* is to learn with what vigour and success the study of a great variety of these problems is being undertaken in the Chemical Research Laboratory at Teddington. At the same time, one is tempted to wonder whether in these progressive, competitive, and anxious days a team of a dozen such laboratories, all concerned with fundamentals, taking the long view, undisturbed by the absence of immediate profit, yet at all points initiating, supporting, and supplementing the activities of private industrial research organizations, would prove supernumerary to the desirable national establishment. To wonder anything of the kind is perhaps itself a tribute to the significance of the Teddington laboratory and an appreciation of its work.

For greater convenience in administration, the work of the laboratory is divided into ten sections. Study of the corrosion of metals involves considerations ranging from the composition of rust and the velocity and mechanism of its formation, to the conditions under which metals are attacked in stagnant or moving salt solutions and to the corrosion of locomotive boiler tubes, water supply systems, and fire extinguishers. The use of magnesium-rich alloys of the electron type in the manufacture of fuel tanks has hitherto been handicapped by the corrosive action of 'leaded' fuels in the presence of water. The separate main constituents of the anti-knock mixture, when mixed singly with petrol and water, have little effect, but together they may give much trouble It has been discovered that this severe corrosion can be entirely suppressed by the addition of 1 per cent of quinoline, which does not affect the anti-knock properties of the fuel

---

*Report of the Chemistry Research Board for the Triennial Period ended 31st December 1937; with Report of the Director of Chemical Research. Pp. vii+146+7 plates. (Department of Scientific and Industrial Research.) (London: H.M. Stationery Office, 1938.) 3s. net.

High-pressure research has included the synthesis of acetic acid from methyl alcohol and carbon monoxide and an extension to higher aliphatic acids, the manufacture of higher alcohols, and the production of acids from ketones and carbon monoxide. Thus acetone and carbon monoxide under pressure in presence of phosphoric acid afford acetic and trimethylacetic acids, apparently by condensation to mesityl oxide followed by hydrolytic fission to *iso*butylene and acetic acid, the former then affording trimethylacetic acid and hydrocarbons. Experiments on the catalytic production of higher from lower alcohols have led to the determination of optimum conditions, and to the observation that the carbon monoxide employed is not an indifferent gas, but plays some part in bringing about the reactions concerned Incidentally, it has been found that, owing to the risk of explosions, great caution is needed in the use of di-*iso*propyl ether.

The researches on coal, tar, and rubber comprise, as would be expected, a great deal of work on hydrogenation. Coal, in the form of a colloidal suspension in a suitable oil, can be hydrogenated in a pipe system with 85 per cent conversion to oil. Experiments on the hydrogenation of naphthalene derivatives and of pyrene are also described. One interesting research was concerned with the composition of wood smoke as used in the curing of fish; another had as its object the development of new uses for chlorinated rubber.

Chemotherapy is represented by important work on pyridines, cyclic diazalines, and arsenicals, one of which, 'neocryl', is being subjected to extensive clinical tests.

The synthetic resins studied were obtained from phenolic or ketonic sources; both X-ray and electrical methods have been used. It is concluded that phenolic resin films can best be regarded as composed of irregularly shaped aggregates which are in contact at some, but not all, of the chemically active points. Catechin and gambier can now be used in the manufacture of laminated and moulded products. It is remarked that the present industrial development of colourless resins lends interest to attempts to produce transparent, glass-like ketonic resins, the preparation of which promises to be a comparatively cheap process.

Of particular interest in connexion with water pollution is the observation that many resins from polyphenolic substances possess good base-exchange properties Acid-exchange resins can also be prepared, so that it is possible to use these two types of resin successively to remove dissolved solids from tap water In the example given, the reduction was from 36 parts to 1 part per 100,000. An investigation has been made into the possibility of contamination of drinking water by lead arising from the use of water mains for earthing electrical apparatus. Although the necessary current would not be carried by house fuses, damage may occur to the outside of the pipes by this means A method of sampling, whereby the actual amount of lead present in water used for drinking and cooking purposes can be ascertained, is of value in assessing the suitability of domestic water supplies from this point of view.

The report on microbiology refers to the bactericidal action of oxygen under pressure at temperatures little above the optimum growth temperature The Rideal-Walker test for disinfectants has been examined, and it is found that constancy of results is very difficult to secure. In connexion with the differentiation of strains of micro-organisms, it has been shown that acclimatization to growth at temperatures higher than the general optimum varies with the strain, and that in some cases the outstanding difference is in the sodium chloride requirement Thus, for each strain of *V. aestuarii* the salt concentration tolerated reflects its origin, whether from sea water, estuarial water, fresh water, or soil, in spite of prolonged sub-culturing on media free from sodium chloride.

Studies on road tar were concerned not only with composition but also with behaviour in the open air. The surface skin formed by the combined action of evaporation, oxygen, and light is more impervious than that produced by evaporation only.

General research includes work on compounds of rhenium, ruthenium, osmium, and iridium, on the occurrence of germanium and gallium in coal, on polypyridyls and phenanthridine derivatives, and on the production of carbazole from *o*-xenylamine.

The report on chemical engineering refers to the erection of a turbulent flow high-pressure plant, to a high-pressure flow meter, and to a study of the action of hydrogen on steels at high temperatures and pressures.

Maps and Plans of Great Britain

A DEPARTMENTAL COMMITTEE on the Ordnance Survey was appointed by the Minister of Agriculture and Fisheries on May 28, 1935, under the chairmanship of the Right Hon Sir John Davidson (now Viscount Davidson), with the following terms of reference:

> "(*a*) to consider what measures are necessary to accelerate the revision of the Ordnance Survey Maps in order to bring them up-to-date and thereafter to maintain them at a high level of accuracy, while providing for such other public services as are undertaken by the Ordnance Survey Department;
>
> (*b*) to consider what immediate steps are possible in the meantime to revise Ordnance Survey Maps to the extent necessary for the purpose of town and country planning schemes;
>
> (*c*) to review the scales and styles of Ordnance Survey Maps placed on sale to the public, and to recommend whether any changes are desirable; and
>
> (*d*) to review the conditions upon which the reproduction of Ordnance Survey Maps is permitted."

At the time, the most pressing problems in these terms of reference were considered to be the provisions of maps for town and country planning, and the question of the condition upon which the reproduction of maps should be permitted, that is, paragraphs (*b*) and (*d*); and the Committee accordingly issued an Interim Report* dealing specially with these points, dated December 21, 1935. The final report†, dealing with items (*a*) and (*c*), was published on November 3 last, although it appears to have been signed so long ago as February 3.

The recommendations are, we believe, more far-reaching than those of any of the many previous inquiries which have been held on the Ordnance Survey. It is well known that the basic plans of England on the scale of 1/2500 (popularly known as 25 inches, actually 25 344 inches, to a mile) on which all the maps on smaller scales depend, were plotted as separate projections each embracing a county, or group of counties, having their own independent origins. This resulted in no fewer than thirty-nine separate projections being used for these plans, which comprise 51,456 sheets. That such a system should ever have arisen seems, to-day, surprising, but it grew up, like many British institutions, in a haphazard way, counties being selected for survey according to their supposed importance irrespective of their geographical situation. Gradually practically the whole country has been surveyed on the 25-inch scale.

Only the surveyor can really appreciate the inconvenience, not to mention the extra cost involved, especially when maps have to be revised, of this state of affairs. The Committee has fully recognized this, and it is recommended, therefore, "that as soon as it can be conveniently arranged the 1/2500 survey should be re-cast on national instead of county sheet lines on a national projection".

The re-casting of the 1/2500 series will involve the re-drawing of the whole series, which would in any event have been necessary with the majority of the sheets, in order to bring them up to date. The opportunity should therefore be taken, the Committee recommends, of altering the size of the sheets, which would apply to all scales of maps, and introducing a national grid to provide one system of reference for the maps of the whole of Great Britain. This would make it possible to apply a single reference system to all maps by which any point can be precisely defined either on the ground or on the map. The significance of this from a defence point of view, since maps of every part of the country are now liable at any moment to become of military importance, cannot be exaggerated.

It is recommended that the unit for this grid should be the international metre, which has many advantages, being on a decimal system, over any other unit. Under this arrangement the shape of the 1/2500 plans would be square, with one kilometre sides, while the 6-inch sheet would consist of exactly twenty-five 1/2500 plans. Another advantage of the application of the grid to maps is that it would provide a universal index to maps on all scales, serving the needs both of the general public and of the technical map users. Map sheets would be known by the grid co-ordinates of their south-west corners. The only condition in order to fulfil the function of an index is that the limits of sheets should be coincident with grid lines.

The natural sequence of scales derived from the basic scale of 1/2500, would be 1/25,000 and 1/250,000. The latter differs from the existing ¼-inch scale by only 1¼ per cent, a difference scarcely perceptible to the great majority of those using this particular scale. The Committee, however, did not see its way to recommending a change, though it does suggest, as an experiment, the introduction of the 1/25,000 as a new scale, with this exception, all the old scales remain the same.

---

* Interim Report of the Departmental Committee on the Ordnance Survey. Pp. 16. (London: H.M. Stationery Office.) 3*d*. net. See NATURE, May 2, 1936.

† Final Report of the Departmental Committee on the Ordnance Survey (Ministry of Agriculture and Fisheries). Pp. iv+39+11 maps. (London: H.M. Stationery Office, 1938.) 5*s*. net.

The new scale, which is approximately 2½ inches to the mile, is of the utmost military importance, and this consideration alone would warrant its introduction. On this map it would be possible, with the help of the national grid, to find quickly and easily the exact distance and azimuth of any one point from another, even should the points fall on different sheets. According to the specimen shown in the Committee's report, contours would be in brown at 5 ft. intervals, and we believe, if the detail is not overcrowded, that this scale should prove popular with the general public

It is a pity the Committee did not see its way to a complete reorganization of the map scales of Great Britain, so as to conform to modern ideas Doubtless the prejudice in favour of our peculiar form of measurement was considered to be so great that a rational system of map scales would be unacceptable.

The question of revision within a reasonable time of the existing out-of-date 1/2500 plans and their future maintenance was carefully gone into by the Committee It is considered that air photography should prove useful for this purpose, especially in a country where the surface is altering so rapidly *It is recommended that the* Government should consider the formation of a special Air Survey Unit, capable of satisfying the requirements of the Ordnance Survey Owing to the small numbers of 'photographic days' in the year in Great Britain, it would be necessary to find employment for such a unit in some other part of the Empire during the English winter months This should not be difficult, as maps and photographs are urgently required for development purposes. It would also be necessary, for the best and most economical results, to build special aircraft suitable for photographic work

An appendix deals with the proposed national projection and suggests a modified transverse Mercator projection on a central meridian 2° West as most suitable. The net effect of the adoption of this projection would be to make the scale of plans in the central portion of the country, in the vicinity of the adopted meridian, about 1/2501 (0·04 per cent) too small, and the scale of the plans in the extreme east and west coasts about 1/2499 (0·04 per cent) too large, the scale of the intermediate places varying between these limits. A slight variation in scale cannot be avoided in a representation of the curved earth's surface on a plane surface, but these amounts are within the expansion of paper due to variations of atmospheric humidity.

The following is a summary of the Committee's recommendations ·

The 1/2500 scale should be retained, and should be re-cast on national instead of county sheet lines on a national projection While this work is in progress, there should be a general overhaul of the plans to eliminate the errors which have crept into the original survey in course of revision. A national grid should be superimposed on all large-scale plans and on smaller scale maps, with certain exceptions, to provide one reference system for the maps of the whole country The international metre should be adopted as the unit on which the grid should be based, and the large-scale maps in the new national series should be square in shape The 1/2500 plans when re-published in the new national series should cover one kilometre square of country, while the one inch to the mile and smaller scales should be retained in their existing form The existing six-inch plates should be retained for printing on demand for special purposes The scale of six inches to the mile should be retained, and maps on this scale should be produced in the new National Series in a square shape and containing twenty-five 1/2500 plans A new medium scale of 1/25,000 should be tried out experimentally in certain selected areas, and, if successful, should be extended to cover the whole country in a National Series

It is also recommended that when the revision of the 1/2500 plans has been completed, further investigations should be carried out with the view of establishing whether the requirements of urban areas would not be more adequately met by a survey on the 1/1250 scale When a suitable opportunity occurs, additional contours should be introduced, and the numbering of parcels should be discontinued as soon as the national grid is introduced It is also recommended that the Ordnance Survey should continue to publish archæological maps. The existing arrangements for revising the one-inch and smaller scales should continue, but a system of continuous revision should be adopted for the large-scale plans as soon as practicable Short-term contracts to civil firms, for aerial photographs, should not be continued as a permanent policy, it is suggested that the Government should consider the formation of a special Air Survey Unit, capable of satisfying the requirements of the Ordnance Survey, as soon as practicable. The Committee also recommends that the position of the Ordnance Survey should be reviewed annually with a view to the maximum practicable recruitment, until the recommendations made have become effective, and that the work should be adequately maintained.

News and Views

R. W. Paul: Award of Duddell Medal

THE Duddell Medal of the Physical Society has been awarded to Mr. Robert W. Paul, who is known as a pioneer in two distinct industries, namely, the manufacture of electrical measuring instruments and the development of the cinematograph. Mr. Paul started on his own account as a maker of electrical instruments at 44 Hatton Garden in 1891, and with the collaboration of many of the chief electrical engineers of the day, produced a series of instruments which found their way into the majority of the electrical laboratories of the world Amongst these may be mentioned the Ayrton-Mather galvanometers, electrostatic voltmeters, etc The inductometers and other instruments designed by Albert Campbell introduced to industry instruments capable of measuring high-frequency currents to an accuracy previously unobtainable In 1903 he invented the Unipivot galvanometer with which his name has been closely associated. The simplicity, robustness and high sensitivity of this instrument appeal to all users of galvanometers, and it still remains a popular instrument. During the Great War Mr Paul assisted in the development of anti-aircraft height-finders and also of anti-submarine devices. In 1919 Mr Paul's business was incorporated with the Cambridge Scientific Instrument Co. under the title of the Cambridge and Paul Instrument Co, later changed to the Cambridge Instrument Co.

MR. PAUL is also known as one of the pioneers of the cinematograph. Next to Edison he did more to develop the 'kinematograph' or 'theatrograph', as it was then called, than any other individual. His projector was first shown in operation at an entertainment at the Finsbury Technical College in February 1896; his form of intermittent motion for feeding forward the film is still employed. For many years Mr. Paul exerted himself to improve the training of young instrument makers, and it was on his initiative that the apprentices' or learners' section was introduced into the annual exhibition of scientific instruments held by the Physical Society. Finally, in very recent years, he has turned his skill in co-operation with Sir William Bragg, to the humanitarian task of making a practicable device for continuous artificial respiration. This apparatus has already saved the lives of many sufferers from infantile paralysis.

Man and Mammoth in America

IN a preliminary statement issued by the Smithsonian Institution, Washington, Dr. F. F. H. Roberts, jun., reports that in the course of last summer, his fifth season of excavation of the camp station of Folsom man on the now famous Lindenmeier site in northern Colorado, he recovered a large number of bones of the animals which formed the food of Folsom man, together with several new types of knives and scrapers, but all unquestionably showing signs of Folsom workmanship. Bones engraved with geometrical designs were again found, but none showing any attempt at either picture writing or the representation of animal forms Associated with the implements was the tusk of a mammoth. Although remains of the mammoth have been found in association with relics of Folsom man in New Mexico, this is the first indication of its presence on the Lindenmeier site

DR. ROBERTS has also made a reconnaissance in two other regions, one near the town of Sundance in Wyoming, the other near Mortlach in Saskatchewan The first yielded a number of the so-called "Yuma' points, long, slender, but heavy projectile points, or spear-heads, which are believed to bear some relationship to the Folsom point, but no evidence of Folsom man was found. In Saskatchewan, a site in the midst of the Canadian dust bowl was investigated A few Folsom points were found, but the majority were o the Yuma type. Unfortunately, owing to the conditions of the soil, in which all heavy artefacts work down to the bottom of the deposits, no evidence o stratification was obtainable. Nevertheless this result is of considerable importance. A few scattered points have been reported from time to time on the Great Plains extension into Canada; but this is the firs concentration of these nomad hunters to be reported so far north The bearing of the find on the question of the antiquity of man in North America is at present obscure, as there is no evidence to show whether these points are a relic of the entry into America or of the period when man was following the retreat of the ice sheet. Until it is agreed whether the Yuma point is pre- or post-Folsom, it affords no guidance.

Antiquities from London for Tasmania

AT an early date Tasmania will receive from the Corporation of the City of London a gift of a number of antiquities found within the boundaries of the City This gift is made under a scheme of the Corporation for promoting in the Dominions and Dependencies an interest in the past history and culture of the central city of the Empire. The collection for Tasmania, which will be housed at Hobart, will include, according to a list given in *The Times* of December 22, some one hundred and forty objects, classified under sixty-eight headings, illustrating daily life in London throughout the centuries from Roman to medieval times. About one half of the objects belong to the Roman period. Among them are coins of eight emperors, bone pins and needles, bone and bronze spoons, knives, iron nails and wooden writing tablets. Among the pottery objects is an example of the work of Eucarpus, a lamp-maker working in London at about A.D. 100, many of whose lamps have been found. There is also a mixing bowl of about the same date, such as seems to have been in use in most Roman kitchens. It is of coarse white ware, roughened on the inside with grit. It bears the stamp of the maker—Albinus of Lyons. Samian ware, so-called, is represented by, among other pieces, three bowls and some fragments of the more elaborate decorated work. There are several of the leather soles of the Roman shoes which are frequently found in London in a good state of preservation. Pottery forms a large proportion of the medieval exhibits; but there are also examples of tradesmen's tokens, bronze 'jettons' or 'casters', used in keeping accounts and making calculations in the Middle Ages, wine bottles, and other domestic objects, including examples of the familiar clay smoking pipes of the seventeenth and eighteenth centuries.

University of Prague

DR. GUSTAV ORTNER, of the Institut für Radiumforschung, Vienna, writes in connexion with the paragraph on the future of Czechoslovakia in NATURE of October 8, p. 637, that it gives an inadequate idea of the historical development of the universities in Czechoslovakia He continues, "the University of Prague [was] founded by the German Emperor Karl IV in 1348 and so is the most ancient German university. It was only in the course of the nineteenth century that lectures in Czech were given and in 1882 an independent Czech University was separated off from it. In 1920 the ancient name of 'Karls-Universität' of the German University was transferred to the Czech University. . . ." Obviously it was not possible to go into details in a brief paragraph, but the facts were correctly given It is true that Charles IV (Karl in German, Karel in Czech) was not only king of Bohemia but Holy Roman Emperor as well, yet it was as king of Bohemia that he founded the University of Prague, and the 560th anniversary of his death was celebrated there on November 27. The Czech character of the University was emphasized by his son, Wenceslas IV, in a special decree in 1409. The University of Vienna dates from 1364, and that of Leipzig from 1409, having been founded in Saxony as a challenge to Prague at a time when Czech was used as well as Latin, which was naturally the main literary language there as everywhere at that time. Thus, the University of Prague is the oldest in Central Europe, but by its foundation it cannot be considered a German university. From 1620 until 1882 it was styled the Charles-Ferdinand University. Afterwards Prague had two universities, the Charles (Czech) and the Ferdinand, or now simply, German University. Another correspondent refers at length to a number of distinguished Prague biologists and the mathematician, Bolzano, not mentioned in the further article, in NATURE of November 26, p 942.

Mathematical Films

THERE has been a considerable increase of interest recently in the use of films for mathematical teaching. The *Mathematical Gazette* of October 1938 and the *American Mathematical Monthly* of the same month both contain reviews of such films, but the majority of the films mentioned are not available in Great Britain. Mr. B. G D. Salt, of 5 Carlingford Road, Hampstead, N W 3, sends us a list of five films that are now available and can be obtained from him. Two of these are geometrical, dealing respectively with the theorem of Pythagoras concerning right-angled triangles, and with the sum of the angles of a triangle. Two others deal with differential equations, by a method devised by Robert Fairthorne, one for the differential equation of free harmonic motion, and the other for harmonic motion when the vibrations are forced The principle for free vibrations was explained in NATURE of October 24, 1936, and that for forced vibrations is somewhat similar. These four films occupy one reel each.

THE fifth film, entitled "A Hypocyclic Motion", which shows much more than its title suggests, is sold divided into three short reels In reel 1, a rigid bar moves with its end on two fixed straight lines. The instantaneous centre of rotation traces out the body and space centrodes, and it is shown that the motion can be produced by the body centrode rolling on the space centrode In reel 2, points on the circumference of the rolling circle trace out diameters of the fixed circle, showing simple harmonic motion. The motion is also shown to be derivable by another epicyclic motion In reel 3, we have an ellipse described as in the tool known as the elliptic chuck, also Oldham's Coupling, and the four-cusped hypocycloid. Finally, the reel shows the generation of an envelope by a moving line The two geometrical films are on 16 mm. only, but the other three can be obtained on 35 mm., 16 mm , or 9·5 mm. There is still considerable doubt as to the part that films should play in mathematical education. The Mathematical Association has set up a film sub-committee to consider the subject. Anyone who has suggestions to offer, especially suggestions for specific films, should send them to Miss M. Punnett, 17 Gower Street, W C.1 Approved suggestions will then be passed on to the manufacturers.

British Bird Song Survey

THE preliminary report on the first year's record of the bird song survey in the British Isles, carried out under the auspices of the British Trust for Ornithology during August 1937–August 1938, states that some eighty observers took part and there are records of the song period of the mistle-thrush from 52 localities, the song thrush from 76, blackbird from 74, chaffinch 63, yellowhammer 35 and skylark 48 Sussex and Cheshire were well covered, but there were only two sets of records from Ireland, three from Scotland and one from Wales, and none from Cornwall, Dorset, Lincolnshire, East Yorkshire, Durham, Northumberland, Stafford, Shropshire or Hereford. 10–15 per cent of the records were very incomplete, being made over less than nine months, and scarcely a quarter of the observers lived in the country and could listen to bird song throughout the day. One observer suggests that by no means all the male birds of even these common species sing at all, so that future observations are to give close attention to this point. The cold spring no doubt reduced bird song considerably in some localities. Several of the best-filled forms came in from clergymen, but fortunately a greater list of observers has been obtained for the repeat of the survey now under progress, especially from Ireland Most parts of England are fairly well represented. A good many observations, however, have been kept by people whose weekday hours of observation are very limited, especially during the short winter days.

Agricultural Meteorology in India

IN the report of the Agricultural Meteorology Section, India Meteorological Department, for the period August 22, 1935–March 31, 1937, it is stated that after reviewing the work done during the first three years of the scheme, the Imperial Council of Agricultural Research communicated to the Government of India a resolution to the effect that the Agricultural Meteorology Section should now become one of the permanent activities of Government, and that proposals for giving effect to this resolution are now under consideration by the Government of India. Work on the experimental or biological aspects of agricultural meteorology, and the maintenance of co-operation with agricultural institutions and workers in India, have been the principal concerns of the section during the period under review, the biological work being carried on mainly at the Central Agricultural Meteorological Observatory at Poona. Among subjects of research were the invisible condensation of water vapour on the soil at Poona, made evident by the decrease during the night in clear weather of water vapour in the layers of air just above the bare ground and by the increase of surface soil moisture to a maximum just before sunrise without visible deposition of dew. It was found that of all samples of soil tested, the black cotton soil of India was, when desiccated, the most efficient absorber of moisture. Researches carried out into the cooling of the earth's surface and of the lower layers of the atmosphere at night in clear weather led to the discovery that at Poona in winter the air temperature has a minimum some distance above the ground. The radiation received from the sun and sky on unit area of a horizontal surface near the ground was measured by means of a Moll solarigraph, and from the records obtained a diagram was constructed showing the intensity of the radiation at different hours of the day in different months.

Uni-directional Lighting on Roads

THE increasing use of double carriage-way arterial roads has given new problems to the street lighting engineer. Some of these are discussed in a paper on the revealing power of street lighting installations read by J. M. Waldram to the Illuminating Engineering Society on November 8. On a double carriage-way road where each carriage-way carries traffic proceeding in one direction only, an ordinary street lantern throws much of its light in the direction where it may be doing no good, that is, in the same direction as the traffic flow. This light is not only wasted, but sometimes also does harm by lighting up vertical surfaces and reducing their contrast against the bright background of the road surface. Elimination of light sources not actively producing road brightness, should result in a great increase of comfort to the drivers. The G.E.C. Research Laboratories have evolved a system of uni-directional lighting which they have tested on the carriage-way of the Great Chertsey Road in the Twickenham area. On this road the standards exist on a double staggered formation; the height of the lantern is 25 ft. and the average spacing of the standards about 189 ft. Each lantern was equipped with a 250-watt horizontal burning lamp and was uni-directional Both visibility and revealing power were found to be very good. Driving in the opposite direction on the other carriage-way, the road lighted with back cut-off lanterns disappeared completely. Traffic moving on it could be distinguished quite easily by the vehicle lights, but apart from this the impression produced was that of driving down a single carriage-way road with no traffic in the oncoming direction. The back cut-off lanterns on the other carriage-way were completely invisible The conclusions drawn are that it is practicable to light a 'one-way' road with lanterns giving light only in the direction opposed to the traffic An installation of this nature saves 50 per cent of lamp wattage.

Loud-speaker Systems on Railways

LOUD-SPEAKER systems are being installed on an ever-increasing scale on railway platforms. A critical discussion of them by O Vogel and K. Rothe is given in the second number for 1938 of the quarterly *Review* published by Siemens and Halske. Until quite recently, orders were shouted to the shunters by the shunting foreman or optical signals were employed. But these methods had certain drawbacks Shouting was the most satisfactory, partly because it is independent of weather or illumination but mainly because it is heard by the shunters in any position. The transmission of orders by means of loud-speakers is an improvement as it ensures a uniform distribution of ample acoustical energy over the entire shunting yard, and all the requirements of safety and speed are satisfied. The old but satisfactory method of calling out times of departure in railway station waiting-rooms could never be entirely replaced by means of optical devices. The introduction of loud-speaker systems has now supplemented optical train indicators very helpfully and these devices are at the same time available for many other kinds of announcements. The authors also discuss portable loud-speaker systems suitable for race-courses, etc., where the normal traffic is small To ensure the complete success of a stationary system, it is necessary to study the local conditions in every case. In halls, waiting-rooms and corridors, difficulties are often encountered owing to echoes.

Thickness of Metal Walls

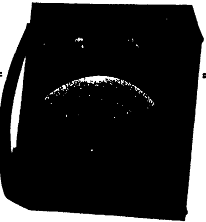
A PAPER by B. M. Thornton and Prof. W. M Thornton, upon which written discussions are to be sent to the secretary of the Institution of Mechanical Engineers before January 31, 1939, gives a method

ANNUAL EXHIBITION

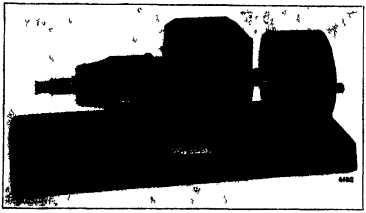
arranged by

THE PHYSICAL SOCIETY

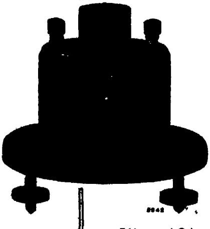
Imperial College of Science, South Kensington,
January 3rd, 4th & 5th, 1939



Multirange Wattmeter



Einthoven String Galvanometer



D'Arsonval Galvanometer

Our exhibit this year is devoted to a full and comprehensive display of GALVANOMETERS of all kinds from the simplest instrument for students' use to the most refined and highly sensitive instrument for the research worker A series of METER-TESTING INSTRUMENTS is shown working in conjunction with auxiliary apparatus as required for a Meter Testing Station

We shall be pleased to discuss any instrument problems at our stand (No 6) Tickets of admission to the exhibition gladly forwarded upon request.

MACMILLAN'S NEW BOOKS

Engineering Science

By H. B. BROWN, B.Sc.
Headmaster, Bordesley Green Technical School, Birmingham
and A. J. BRYANT, B.Sc.
Head of the Junior Technical School, Handsworth Technical College, Birmingham

Volume I. Applied Mechanics and Hydraulics	5*s.*
Volume II. Heat and Heat Engines, and Electrotechnics	6*s.*

A progressive course, with full treatment of experimental work, covering the Engineering Science course of the Junior Day Technical School and of the 1st and 2nd Year National Certificate courses in Mechanical Engineering.

The Essentials of School Algebra

By A. B. MAYNE, M.A.
Headmaster of the Cambridge and County High School for Boys

This book contains all the material needed in a school course up to, but not including, Permutations, Combinations and the Binomial Theorem. It has been written to meet the requirements both of the ordinary pupil and of the pupil who will specialise later. *Complete: With Answers, 5s., Without Answers, 4s. 6d. Also issued in Parts.*

World Geography

By E. O. ROBINSON, M.A.
Geography Master, University College School

Outlines of the geography of the World, including the elements of physical geography, particularly with reference to the earth as the abode of man. The standard is that of the School Certificate Examinations. *With 191 Maps and Diagrams.* 5*s.*

Elementary Inorganic Chemistry

By SYLVANUS J. SMITH, M.A.
Chemistry Master, the High School, Newcastle, Staffs

The scope of this book is intended primarily to be that of a two years' course to reach the standard of School Leaving Certificate Examinations; in particular, the requirements of the University of London and of the Northern Universities Joint Board for these examinations have been considered. 4*s.* 6*d.*

WEATHER

By GAYLE PICKWELL, Ph.D.

170 pages, 11¾ x 9¼, 54 full page plates, 18/- net.

AN extensive and superb collection of actual photographs taken under natural conditions which tell the story of weather in all its phases Comprehensively the author has unfolded the story of weather in words and pictures which will delight not only the meteorologist but the scientifically-minded reader who is not a specialist in the subject

Clouds, their names and formations, what they are made of and the part they play in the plan of nature, and how to identify them, is just a small part of the work

The wind, sun, rain, hail, snow and ice all have a share with the oceans, mountains, deserts and lakes in telling the story of the weather and none is neglected in this fascinating book Plans are given for making the instruments necessary for carrying out elementary meteorological observations

of measuring the thickness of metal walls from one surface only by electrical means A reference was made to this device by Prof Thornton in his contribution to the discussion on non destructive testing at the Institution of Electrical Engineers on November 25 He states that there is a definite need in the engineering industry for an instrument which will determine accurately the thickness of a metal wall from one side only, especially if it is easy to operate, robust, portable, and independent of external power supply It is claimed that the instrument described in the paper fulfils all these conditions The method is essentially that of comparing the resistance of the metal wall under test with that of a similarly shaped wall of the same material, of which the thickness is known Current usually less than ten amperes is supplied by a 12 volt battery to two current contacts held against the wall and usually spaced about three inches apart The current in the circuit is adjusted by varying the rheostat or the number of cells of the small motor car battery employed until the very small potential drop indicated by the deflection of a galvanometer connected to two potential contacts reaches a predetermined fixed value The instrument was originally designed for measuring the thickness of boiler tubes, and examples are given showing that its accuracy is within a few thousandths of an inch It has been found in practice that the instrument can be used to measure the thickness of mild steel plates up to 1 25 in and of iron castings up to three inches, with the same order of accuracy It can also be used for the measurement of engine cylinder walls to detect core shift

World-Wide Survey of Education

IN this year's issue of the well known biennial official survey of education in the United States is included a sketch of the salient features of the history of education in other parts of the world in the decennium 1926–36 (Washington, D C Govt Printing Office, 1938 Pp 98 15 cents) It was an era of drastic—in some countries of revolutionary—changes In Europe, sudden changes in the direction of educational policies were effected in connexion with general revolutionary movements in Austria, Bulgaria, Germany, Portugal, Spain and the Soviet Union Pronounced but gradual changes, long planned and deliberately considered were introduced in Czechoslovakia, England, France Norway, Poland and Sweden The most conspicuous movements in Europe were in the direction of nationalization One aspect of this tendency was the ousting of private by public schools, notably exemplified in Norway and Albania, another, manifested throughout Europe, was the increasing subjection of private schools to public regulation, another, the placing of more of the support and administration of schools in the hands of national instead of local officials, yet another, the progress attempted, with varying success, towards the goal of equal educational opportunity for equal intelligence The doctrine that education is a public function has, in fact, achieved general acceptance, and States 'have been rapidly taking wider and closer control of their cultural institutions, but not always in the way that advocates of public education have desired

NATIONALIZATION in the extreme sense of subordination of all other educational aims to the purpose of promoting and perpetuating the national Government's political and economic theories and practices was established in Italy, the Soviet Union and Germany The survey briefly indicates its outstanding features and some sources of information about it Attention is directed to the fact that in the Soviet Union communistic doctrine has had a much less important place in the school curriculum since 1934 than before Other sections deal with European educational history under such headings as adult education physical education, technical and vocational education A chapter on Latin America points out that the spirit of intense nationalism so rampant in post War Europe has manifested itself there also A formulation of the purposes of the education policy of Colombia for example, contains the following We no longer speak of public instruction but of national education the state ought to educate, that is to say, form the will and heart of the youth rather than instruct by loading them down with knowledge more or less useful However the extreme type of nationalization found in Italy Germany and the Soviet Union has no counterpart in America except in Mexico, and this example is not likely to be followed we are told, in other Latin American countries Throughout these countries a very lively interest in the problems of vocational training has been aroused and developments have taken place that deserve study elsewhere

Education in Civilian Camps

A BULLETIN by H W Oxley director of civilian conservation corps camp education issued by the U S Department of the Interior (No 19 1937), describes the growth and development of camp education, particularly its achievements in vocational guidance and in recreation The programme endeavours to develop powers of self expression, self entertainment and culture, and to promote co operation, in addition to vocational instruction, attempts have been made to remove illiteracy and to correct common school deficiencies The Bulletin also includes a summary of three university studies in counselling and guidance technique in camp education, which indicate that only a beginning has been made in the camps with job and vocational instruction Most of those enrolled come from the working class, and about 12 per cent of those interviewed had received no vocational guidance Many of those enrolled regarded the camp as a transition from home to employment, and the studies indicated the necessity for much more comprehensive vocational training and more careful interviewing A further study of successful practices in the development of a co-ordinated recreational programme in these camps, in which four universities participated, is also summarized in the Bulletin This analysis of activities indicated the pressing need for adequate space, equipment and instructors, and led to a number of definite recommendations for the development of a co-ordinated programme for leisure time in C.C.C camps.

The Radio and Culture

AT the recent annual meeting of the Institut de France, Dr Georges Duhamel, the well-known writer and editor of the *Mercure de France*, deplored what he called the *constitutional defects* of the radio, which he declared has an unfavourable and even demoralizing effect on the intellectual habits of the middle classes. In the first place he asserted that the radio draws many persons away from reading by depriving them of part of their leisure and making them gradually lose the habit of active cerebral work Some people, he continued, are misled by the radio into imagining that the mind can attend to two objects at the same time, which is a mistake Far from contributing to true culture, the radio encourages a taste for superficial ideas which are easily acquired and soon lost In answer to the objection that the radio adds to without supplanting the other modes of information and knowledge, Dr. Duhamel maintained that we cannot safely disregard or decry a system of culture which has been tested for centuries in favour of a new process of which the remote results are necessarily quite unknown As regards the plea that the radio is a source of pleasure, Dr. Duhamel retorted that no pleasure can last several hours a day, and that for some people the radio ceases almost at once to be a pleasure and becomes a craving.

London School of Hygiene and Tropical Medicine

THE report for 1937–38 of the London School of Hygiene and Tropical Medicine by the dean, Prof. W. Jameson, recently issued, surveys the administrative changes and the teaching and research work of the School during the year. In the Departments of Bacteriology and Epidemiology studies have been in progress for eighteen months on the effect of diet on the fertility, survival and growth of mice, and their resistance to infection, which show that a diet containing a proportion of animal protein, compared with one containing vegetable protein only, renders individual mice more resistant to infection of *Bact. typhimurium*, and significantly reduces the mortality in herds in which the disease is spreading by natural contact. In the Department of Entomology much work has been done on the biology of mosquitoes, the bed bug, lice and other parasites, and an important investigation continued on the spread of mineral oils on water in relation to anti-malarial work by destruction of mosquito larvæ In the Department of Bacteriology studies have been continued upon the isolation of the antigenic components from various bacteria, and their value as immunizing agents. The physiological problems of air raids precautions, in particular gas-proof clothing, helminthic parasites of domestic animals, and problems connected with the root eelworm disease of potatoes, are a few of the other subjects that are under investigation. The Ross Institute of Tropical Hygiene reports upon its anti-malarial work in various Colonies, Yugoslavia and South America.

Malaria in Albania

IN an inaugural thesis (*Thèse de Paris*, No. 548, 1938), F. L. Richards states that malaria is the most prevalent disease in Albania, especially in the low-lying regions, where it is closely associated with the presence of lakes, marshes and other places inundated by the mountain water courses. It is more or less endemic in villages near streams and their affluents. Most of the patients under treatment in the hospitals are suffering from this complaint, which in some parts of the country affects 50 per cent of the population. All clinical forms of the disease are found, malignant tertian being the commonest. In addition to its high incidence in the civilian population, malaria is the most frequent disease in the Albanian army Its prevalence is highest in June, July, August and September, and sometimes there is a rapid rise in the number of cases in October; but August and September are the months in which the disease is most intense. The death-rate is higher in children than in adults. The spread of the disease is favoured by the unhygienic habits of the Albanian people and is therefore most pronounced among the poor. At the suggestion of the King of Albania, a five-year plan has recently been introduced for combating the disease

Microscopy for the Chemist

A RECENT article by Prof Alois Herzog (*Zeiss Nach*, 2, Hefte 5 and 6, 1938) is based upon the value of the microscope to the chemist for qualitative analytical determinations with minimal amounts of material A number of simple methods is described involving the use of sublimation, distillation, precipitation, drying, crystallization, spot reactions, and other procedures with or without the addition of specified reagents, whereby crystals and other deposits having characteristic microscopical appearances are obtained, which serve to identify various metals and metallic and other salts, etc. Screens (sieves), animal and vegetable fibres, and miscellaneous inorganic substances like asbestos, and the use of the polarizing microscope are also briefly described. The article is illustrated with 97 excellent photomicrographs of the appearances obtained in the reactions, and full details are given as to how the objects were photographed, namely the camera, objective and ocular used, the illumination and the time of exposure.

Physics in Crime Detection

THE Physics Forum of the November issue of the *Review of Scientific Instruments* is devoted to an account of the use made of physics in the detection of crime in the United States. It is written by J. Edgar Hoover, of the Federal Bureau of Investigation of the Department of Justice. Although the author refers to the use of radio in rapidly communicating information, the account is mainly concerned with optical methods the microscope for the identification of hair, shreds of clothing or other small particles, for the examination of minute markings on bullets so as to identify the weapon used or the markings on a cut window bar to identify the bolt cutter used and with the addition of polarizing prisms the identification of soil stains on shoes or clothing The spectroscope is used for identification of stains of all kinds ultra violet light for the identification of materials by their fluorescence for the detection of erasures in documents or for reading documents written in secret ink invisible in ordinary light X rays are used for the examination of suspected parcels without opening them and infra red light for reading obliterated writing or printing on paper and other materials

Manganese Ores

IN view of the great importance of manganese ores in modern steel manufacture much interest is attached to a small book by Dr A W Groves on Manganese (Second Edition Imperial Institute 1938 3*s* 6*d* net) It is one of the series of monographs on mineral production Ores occur in many lands but large scale production is confined to the Soviet Union, India the Gold Coast the Union of South Africa, Brazil Egypt and Cuba It is noteworthy that with the exception of the Soviet Union and to a small extent the United States all great steel producing countries have to rely upon imports from distant lands for their supplies of manganese These ores are thus one of the most essential constituents of ocean trade The book gives details of occurrence and production in all lands where the ore has been found and ends with a long bibliography

The Night Sky in January

THE moon is full on January 5 and new on January 20 Lunar conjunctions with the planets occur as follows on January 14 with Mars on January 16 with Venus on January 23 with Jupiter and with Saturn on January 26 Mercury Venus and Mars are morning stars Mercury is at greatest western elongation (23°) on January 3 and Venus reaches greatest western elongation (47°) on January 30 Venus rising shortly before $4\frac{1}{2}^{h}$ U T is pre eminently the bright and morning star Jupiter southing in the early afternoon is conspicuous in the evening sky Saturn is due south shortly after 18^{h} on January 1 The bright stars of the constellation of Orion and its associated constellations are passing the southern meridian about 22^{h} in mid January The Quadrantids radiating from Draco may be looked for about January 2 On January 1, an occultation of the planet Uranus (mag 6 0) takes place, at Greenwich the disappearance occurs at $17^{h}\ 0\ 1^{m}$ at position angle 51° from the north point of the moon's image On January 26, δ Piscium ($4\ 6^{m}$) is occulted at $17^{h}\ 1\ 2^{m}$, and on January 30, ϵ Tauri ($3\ 6^{m}$) at $19^{h}\ 39\ 2^{m}$, the respective position angles at disappearance being 12° and 83° from the north point

Announcements

PROF ERWIN SCHRODINGER has been appointed by the Fondation Francqui as a visiting professor for the next six months to a Chaire Francqui in the University of Ghent Belgium His address is Laboratory of Physics Plateaustraat 22 Gand Belgium

M EDMOND ROTHÉ director of the Institute for the Physics of the Earth University of Strasbourg, has been elected a *correspondant* for the Section of Astronomy of the Paris Academy of Sciences in succession to the late Prof P Stroobant

DR ERROL IVOR WHITE has been appointed deputy keeper in the Department of Geology of the British Museum (Natural History) with effect from December 21 and Mr Frederick Allan Bannister has been appointed deputy keeper in the Department of Mineralogy with effect from December 31 Dr White entered the Museum as an assistant in 1922 He took the degree of D Sc in 1935 and throughout his service at the Museum has specialized on the fossil fishes, upon which he is a recognized authority Mr Bannister entered the Museum in 1927 as an assistant keeper and has specialized in the analysis of mineral structure by means of X rays in the development of which method he has taken a leading part

THE annual meeting of the Mathematical Association will be held in King's College Strand London W C 2 on January 2 3 under the presidency of Mr W Hope Jones The subject of Mr Hope Jones's address will be Simplicity and Truthfulness in Arithmetic Discussions on the teaching of applied mathematics in technical colleges and on the second report on the teaching of geometry have been arranged and papers by Prof W L Bragg on the symmetry of patterns and by Lord Stamp on education and statistical method in business have been promised Further information can be obtained from Mr G I Parsons Peckwater Eastcote Road Pinner Middlesex

THE Government of Cuba has decided to devote a million dollars to the campaign against tuberculosis

A CEREMONY in commemoration of the biologist and physician Lazzaro Spallanzani (1729 1799) will be held at Padua next spring at the same time as the International Congress of Experimental Biology which will be under the patronage of the Italian Academy

THE Alvarenga do Piauhy (Brazil) Prize for 1939 which is worth about 200 dollars, will be awarded by the College of Physicians of Philadelphia in July next for the best memorial or the best unpublished essay on any branch of medicine Recent publications brought to the attention of the committee before May 1, 1939, will receive attention Further information can be had from the Committee for the Alvarenga Prize, 19 South Twenty second Street, Philadelphia U S A

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1163.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Methæmalbumin (Pseudo-methæmoglobin)

IN a previous communication[1], I suggested the name pseudo-methæmoglobin for a new blood pigment, formerly confused with methæmoglobin, which Fairley and Bromfield[2] had found in the plasma of blackwater fever cases. Serial quantitative observations based on the degree of dilution necessary for the extinction of the α bands of pseudo-methæmoglobin and oxyhæmoglobin indicated that pseudo-methæmoglobin was derived from extracorpuscular oxyhæmoglobin. Since then we have demonstrated the same pigment in nocturnal hæmoglobinuria, incompatible transfusion[3] and pancreatic cyst fluid[4]. Foy and Kondi[5] made a spectrographic analysis of this pigment, and confirmed its incidence in blackwater fever in Macedonia.

Experimental Observations. It had long been recognized that, on incubation, solutions of hæmoglobin yielded methæmoglobin and later hæmatin, but our experiments showed that when oxyhæmoglobin was incubated at 40° C. for 24–72 hours in the presence of human plasma, pseudo-methæmoglobin was produced. Similarly, when alkaline hæmatin, prepared from purified hæmin, was added to human plasma or serum, pseudo-methæmoglobin immediately appeared. This suggested that hæmatin was coupling with some protein or other nitrogenous constituent of the plasma to form a new compound. Unpublished investigations last year, undertaken to determine the nature of this unknown plasma constituent, yielded negative results with crystallized horse albumin and with pseudoglobulin and euglobulin fractions of human serum supplied by Dr. Muriel Adair. Further experiments then unexpectedly revealed that only human and simian plasma contained the constituent coupling with hæmatin to form pseudo-methæmoglobin; the plasma of ten other species of mammals gave negative results.

In the light of these later findings, further investigations have recently been made by R. J. Bromfield and me with serum protein fractions prepared by Dr. C. Rimington from man and monkeys (*Macacus rhesus*). Alkaline hæmatin uniformly produced pseudo-methæmoglobin only with the albumin fractions and never with the pseudoglobulin or euglobulin fractions. The different proteins contained in the albumin fraction from human serum, that is, crystalbumin, globoglycoid and seroglycoid, prepared by Dr. L. F. Hewitt, were next tested. Only crystalbumin proved capable of forming pseudo-methæmoglobin. Finally, when 12·5 mgm. of alkaline hæmatin per kilo were injected intravenously into monkeys (*Macacus rhesus*), pseudo-methæmoglobin was immediately formed; similar injections failed to produce it in rabbits.

Spectrum of the Synthesized Pigment. On the Hartridge reversion spectroscope, the α band of synthesized pseudo-methæmoglobin (6230 A.) is colinear with that of pseudo-methæmoglobin produced in intravascular hæmolysis or by incubation, and is not far removed from that of methæmoglobin (6300 A.). In addition, there is a general diffuse absorption commencing in the green about 5485 A. and extending towards the short-wave end of the spectrum. This corresponds with what has been observed in occasional specimens of hæmoglobin-free plasma derived from cases of blackwater fever and nocturnal hæmoglobinuria.

In intravascular hæmolysis, pseudo-methæmoglobin is generally associated with free oxyhæmoglobin, the α and β bands of which approximate to the β and γ bands of methæmoglobin: a composite spectrum results with α, β and γ bands somewhat resembling methæmoglobin. This probably explains why, since Hoppe-Seyler's discovery of methæmoglobin in 1865, pseudo-methæmoglobin has remained unrecognized by the clinical pathologist.

Chemical and Physical Behaviour. There are, however, easily demonstrable differences between the two pigments. Stokes's reagent, ammonium sulphide (10 per cent), sodium fluoride, hydrazine hydrate (50 per cent) and hydrogen peroxide (10 vol.) immediately disperse the α band of methæmoglobin, whereas that of pseudo-methæmoglobin persists with the first three reagents and is only gradually dispersed with the last two. In the presence of sodium hydrosulphite, methæmoglobin forms reduced hæmoglobin, whereas pseudo-methæmoglobin forms a hæmalbumin compound which, on further treatment with sodium hydroxide, produces an albumin-hæmochromogen indistinguishable on the Hartridge reversion spectroscope from globin-proto-hæmochromogen. When pseudo-methæmoglobin is treated with sodium hydrosulphite and coal gas, a carboxy-hæmalbumin compound is formed very similar spectroscopically to carboxy-hæmoglobin.

Other properties of synthesized pseudo-methæmoglobin and of that occurring in blackwater fever serum were reported on by Dr. A. S. McFarlane as follows: "In blackwater serum or in the human albumin-hæmatin mixture the pseudo-methæmoglobin sediments in the ultra-centrifuge at the same rate as serum albumin. The human albumin-hæmatin mixture in the cataphoresis tube shows a homogeneous pseudo-methæmoglobin boundary migrating at a slightly different rate from serum albumin. There is present a small amount of unchanged serum albumin. These facts indicate a firm union of albumin and hæmatin which probably involves chemical linkage."

The data available indicate that pseudo-methæmoglobin is modelled on the methæmoglobin pattern, but that while the prosthetic group is similar, the protein component is native serum albumin instead of native globin. The iron is held in the trivalent state, and is even more resistant to reducing agents than methæmoglobin itself. In view of these findings, I propose, as suggested to me by Dr. Rimington, to change the name of pseudo-methæmoglobin to methæmalbumin.

Physiological Significance Methæmalbumin is never found within the corpuscles, and cannot function as a respiratory pigment It is derived from circulating extracorpuscular hæmoglobin liberated during intravascular hæmolysis, or from blood which has escaped into cysts or other cavities Evidently during the extracellular katabolism of extra corpuscular hæmoglobin hæmatin is formed and in man and monkeys this unites with serum albumin to produce methæmalbumin, the molecular size of which renders it impermeable to the kidney For this reason, it never appears in the urine

The finding that only human and simian albumin combine with alkaline hæmatin to form methæm albumin reveals a hitherto unsuspected chemical difference between these serum albumins and those of other mammals

Production of Artificial Hibernation

As I have shown previously[1,2,3], the serum magnesium of the hedgehog is increased during hibernation and regular sleep, while calcium remains nearly constant While serum magnesium reaches its maximum during the deepest hibernation, the adrenaline of the adrenals and the blood sugar simultaneously show their lowest seasonal values[4,5]

When magnesium injections (1 mol $MgCl_2$) were given subcutaneously to hedgehogs in autumn the animals went into the cold blooded state became very limp and insensible, and the depth and rate of their respiratory movements diminished When the animals under magnesium anæsthesia received a calcium injection (1 mol $CaCl_2$) they returned rapidly to the warm blooded state At the same time, sensibility, muscle tone and motility returned 1 mol sodium chloride solution caused no appreciable change in the animals

Table 1 shows that the magnesium caused also a considerable rise in blood sugar and in the adrenaline of the adrenals After the animals had been revived by means of calcium, adrenaline and blood sugar had fallen again

TABLE 1

	Blood sugar (mgm %)	Adrenaline (mgm %)	Serum	
			Mg (mgm %)	Ca (mgm %)
Normal hedgehogs	125	86	3 2	10 0
After Mg injection	286	100	25 4	11 0
After Mg and Ca injections	138	45	17 3	23 9

The amount of injected magnesium is unnaturally large, but the intention was to give so much magnesium that the body temperature would fall to a level corresponding to that found in hibernation

Typical features of hibernation are the transformation of a warm blooded animal into a cold blooded animal, increase in serum magnesium, hypoglycæmia, and decrease in the adrenaline of adrenals Magnesium injections caused the hedgehogs to go into the cold blooded state, but produced hyperglycæmia and an increase in the adrenaline Therefore to other animals insulin was given subcutaneously with magnesium

These animals also went into the cold blooded state, resembling, in contrast to those which had received only magnesium, very closely naturally hibernating animals Sensibility and muscle tone were preserved The animals were rolled up in the natural manner, and continued sleeping until they were sacrificed for analyses

In Table 2 the results of these experiments are given

TABLE 2

	Blood sugar (mgm %)	Adrenaline (mgm %)	Serum	
			Mg (mgm %)	Ca (mgm %)
Normal hedgehogs	1	86	3	10 0
Artificial hibernation (Mg and insulin)	44		9	1 2
Natural deep hibernation	49	40	6 0	11 9

The results show that blood sugar and the adrenaline of the adrenals in artificial hibernation were approximately the same as in natural hibernation Particular attention is directed to the fact that blood sugar always adjusted itself to approximately the same level as that found in natural hibernation although the amounts of injected insulin varied within a wide range (1 10) Similar amounts of insulin given without magnesium caused fatal hypoglycæmia

Anti-Encephalomalacia Activity of *dl*-α-Tocopherol

RECENT work on K avitaminosis in chicks offered an opportunity of studying the nutritional encephalomalacia of growing chicks receiving certain supplements to their basal diet Some groups of chicks were kept on diet 108 of Pappenheimer and Goettsch[1] On this diet the animals developed the symptoms as described by these authors We have now studied the effect of the addition of certain vegetable products, as it was our intention to carry out an elaborate fractionation of these materials along with the search for vitamin K In the meantime, synthetic *dl* α tocopherol prepared after the method of Karrer *et al*[2] was made available*, and we therefore tested the effectiveness of this substance directly against the disease Daily doses of the substance increasing proportionally to the weight of the animals in quantities of 0 0075 mgm per gm body weight per day completely protected the chicks against encephalomalacia

In an earlier experiment in which another basal diet containing less fat was used, we had already noted that the growth of the chicks was stimulated by the same substance This latter observation is in accordance with the findings of H M Evans, G A Emersom and O H Emerson[3] in experiments with rats

Several authors agree that there are two forms of the anti encephalomalacia factor, namely a fat soluble and a water soluble form The above observations show that the fat soluble form is either identical with, or may be substituted by the synthetic vitamin E It should further be possible to standardize vitamin E in fats by means of the anti encephalomalacia activity

The "Du Noüy Phenomenon"

SOME years ago, du Nouy discovered the very interesting fact that blood serum is able to maintain its normal surface tension When a surface active substance like sodium oleate is brought on the surface of a serum solution, the surface tension is lowered for a very short time, but in a few minutes regains its original value (whereas the decrease of surface tension of water is a persistent phenomenon)

Du Nouy believed this phenomenon to be due to the adsorption of oleate on the surface of the large protein molecules, the oleate molecules being thus eliminated from the surface of the liquid The action of other strongly surface active substances, such as sodium taurocholate and glycocholate, is equally well neutralized by the serum molecules To quote du Nouy, it explains why the liberation of these substances in the circulation does not carry with it a fatal haemolysis of the red cells—in the case of jaundice, for instance—although present in sufficient quantities to lower considerably the surface tension of an equal volume of saline solution The antagonistic action of the plasma proteins counteracts the effect of the excess of bile salts and owing to this phenomenon of defence, the surface tension of the blood is not lowered to a dangerous degree [1]

This interpretation is now generally accepted, and the description of the 'du Nouy phenomenon appears in many text books and reviews on surface phenomena of biological fluids (Brinkman[2], Herčík[3], and others)

In the course of our experiments, we met with direct evidence that the capacity of the blood serum to neutralize the action of such substances as sodium oleate has little to do with colloidal adsorption If we prepare an ultrafiltrate of diluted serum, the fluid, although deprived of colloids, preserves its former capacity to neutralize the action of oleate On the other hand, if, instead of ultrafiltration, we precipitate the calcium ions of the serum by addition of some oxalate, the capacity of such an 'oxalated serum' to neutralize oleate is greatly depressed Finally, we used a pure solution of calcium chloride containing as little as 1 0 or 0 5 mgm per cent calcium, which roughly corresponds to the calcium content of 1 in 10 to 1 in 20 serum dilutions The neutralizing capacity of such calcium chloride solutions did not differ markedly from that of the above serum concentrations

We thus arrive at the conclusion that the neutralization of oleate (and probably also of bile salts) is not a colloidal but rather a salt effect, which is chiefly due to the calcium ions of the serum

A detailed description of these experiments will be published elsewhere

Crystalline Vitamin B_6 (Adermin)

ANALYSES of vitamin B_6 (adermin), isolated in a crystalline state from yeast by Kuhn and Wendt[1] from rice polishings by Keresztesy and Stevens[2] and by Ichiba and Michi[3], established its empirical formula as $C_8H_{11}O_3NCl$ It seems, however, that vitamin B_6 was prepared so long ago as 1932, though its physiological importance was not recognized In a paper by Ohdake[4] dealing with oryzanin (vitamin B_1 from rice polishings) a by product, obtained from the so called basic silver fraction ($pH = 6\ 8–9\ 0$) is described and the formula $C_8H_{10}O_3N\ HCl$ assigned to it.

Considering the properties of the substance, the presence of trivalent carbon or quadrivalent nitrogen is very unlikely, so the total number of hydrogen atoms should be either 10 or 12, instead of 11, calculated from the analyses If twelve atoms of hydrogen are present, the empirical formula of adermin results and, if one compares the properties stated* ('long, colourless plates, easily soluble in water, less in alcohol, not in acetone, benzene, ether etc , melting point 204–205°, uncorrected (decomposition), strong Pauly's reaction , precipitated by phosphotungstic acid") with those reported for adermin, the resemblance becomes very clear

Rigidity in Protein Films, and the Properties of the Force-Area Curves

PROTEINS when spread upon aqueous solutions at sufficiently low surface concentrations exhibit the mechanical properties of two dimensional liquids A change of state occurs upon compression, the film acquiring marked rigidity in the plane of the surface , upon the slender basis of an analogy with the behaviour of proteins in bulk, the film in this rigid condition has been called a 'gel'[1] A consequence of this rigidity is that whereas in the liquid film any change in pressure can be transmitted through a small aperture dividing the film into two portions, this should be no longer possible in the case of the solid film, and the presence of a constriction will result in an uneven distribution of pressures and surface concentrations We have observed such effects in protein films divided by slits of various widths and have also noted in the liquid solid transition region a phenomenon resembling thixotropy

Since considerable pressure differences in films of egg albumin can be maintained indefinitely across a slit 100 mm wide, it seemed possible that even in the absence of a slit, frictional drag at the sides of the trough during compression might cause the film to become heterogeneous , thus the stresses recorded by a surface balance situated at the end of the trough remote from the compressing barrier would not correspond to an homogeneous strain and the resulting force area diagrams would be in error

That such conditions exist in highly compressed films is clearly demonstrated by the following experiment Talcum powder is sprinkled in a narrow thread across the liquid protein film at right angles to the direction of compression Upon compression of the film, the line of powder at first moves uniformly, and continues to do so up to pressures considerably above those at which the slit phenomena referred to above are to be observed , finally, however at pressures of 25–30 dynes/cm , a differential movement becomes apparent, so that the powder near the sides of the trough drags behind that in the centre If the compressed film is left undisturbed the distribution of powder likewise remains unchanged

A direct test of the magnitude of the errors occasioned by this property at various degrees of compression therefore seemed desirable Accordingly, after the force area curve for an ovalbumin film had been recorded in the usual way, the surface was divided into two or three equal parts by means of one or two brass strips (conditioned with ferric stearate) extending from the surface balance to the other end of the trough Thus the area of the film was practically unchanged, while the length of wall in contact with it was in one case doubled, in the other trebled For ovalbumin spread upon 0 01 or 0 10 M hydrochloric acid, the force area curves taken under these conditions were identical, to within 0 1 dynes/cm , with those taken in absence of the longitudinal strips

We conclude that, of the various mechanical properties of ovalbumin films indicated by the character of the force area diagrams, none can be attributed to experimental artefacts arising from the rigidity of the film

An account of these mechanical properties will be published elsewhere

The Lorentz 'Polarization' Correction and the Behaviour of Radio Echoes from the Ionosphere at Frequencies near the Gyro-frequency

In a recent communication[1], we presented certain experimental observations of the reflection of medium radio waves from the ionosphere These results were interpreted as indicating that the Lorentz 'polarization' correction was zero in the ionosphere This conclusion has since been criticized by Appleton, Farmer and Ratcliffe[2] (AFR), and by Booker and Berkner[3] (BB) These two groups of workers advance interpretations of the experimental observations which besides being widely different from ours differ widely themselves

In our communication we showed that for radio frequencies somewhat below the magneto ionic gyro frequency f_H, two echoes were returned from the F_2 region of the ionosphere The echo of shorter delay we identified as the ordinary magneto ionic component The second echo was interpreted, not as the usual extra ordinary component, but as a second component produced by reflection deep in the F_2 region, at the second reflection level of the ordinary component We were led to this interpretation after detailed quantitative consideration of the time retardation and intensity of this echo, which were seriously inconsistent with its interpretation as extra ordinary

AFR suggest that this upper echo is simply the 'extra ordinary component which has been retarded in regions E_1 E_2 and the lower part of F_2 and they point out that penetration into the upper part of F_2 past the first reflection level of the ordinary component is most improbable On the other hand the experimental results of BB show conclusively that the abnormal retardation of this echo is not produced between the E and the F regions Moreover observations which we have made on 440 occasions during the past six months show that the polarization of this echo is a complex mixture and has not the characteristics of the simple extra ordinary component found on higher frequencies

BB, avoiding some of the difficulties encountered on AFR s viewpoint, suggest that the retardation occurs because of lateral deviation in the lower part of the E region Since infinite retardation is found to occur at 1 38 Mc /s in Washington, while the gyro frequency f_H is 1 53 Mc /s at this level they adopt the Lorentz dispersion formula, which gives infinite deviation (and therefore infinite retardation) at the Lorentz frequency f_λ (1 27 Mc /s) In order to reconcile the discrepancy still remaining they postulate the existence of approximately 2×10^6 heavy ions per c c thus bringing f_λ to the observed frequency of 1 38 Mc /s

The accompanying table shows the values of f_H and f_λ at various heights above Washington and Sydney

CALCULATED GYRO AND LORENTZ FREQUENCIES AT VARIOUS HEIGHTS ABOVE WASHINGTON AND SYDNEY

Level	f_H Washington	f_H Sydney	f_λ Washington	f_λ Sydney
Ground	1 61	1 63	1 34	1 48
100 km	1 53*	1 55*	1 2	1 41
200 km	1 4	1 49	1 2	1 35
300 km	1 41	1 43	1 1	1 30
340 km	1 38	1 40	1 1	1 2

We have observed, in Sydney, the frequency at which infinite retardation of the echo in question occurs This happens at a frequency of 1 40 Mc /s , which is very nearly equal to f_λ at a height of 100 km If BB's views are correct, there must therefore be a negligible number of heavy ions at this height above Sydney

It seems to us unlikely that such an enormous difference should obtain between the ionic densities above Sydney and Washington

From our own point of view, the retardation occurs high in the F_2 region, reflection occurring at the reflection level of the second ordinary component Infinite retardation is experienced when $f = f_H \cos\theta$, where θ is the angle between the earth's magnetic field and the direction of propagation. On the wave passing the first reflection point of the ordinary component, however, $\theta \rightarrow 0$ and infinite retardation occurs when $f = f_H$.

The frequencies of infinite retardation experimentally observed at Washington and Sydney are therefore simply explained as being the values of f_H at equal heights (340 km) above these two places Penetration of the wave to these great heights is rendered possible by the fact that it travels *along* the magnetic field, in which direction no barrier exists. If our view be accepted, then the Sellmeyer, and not the Lorentz, dispersion formula is to be applied in the ionosphere, in agreement with Darwin's[4] theoretical conclusion

This work, which will be fully described elsewhere, is published by permission of the Radio Research Board of the Commonwealth Council for Scientific and Industrial Research.

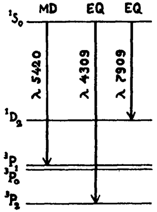
'Forbidden' Lines in the Te I Spectrum

A FEW years ago, one of us developed a method of obtaining the emission of 'forbidden' atomic spectral lines of various metals These lines have appeared in the spectrum of high-frequency electrodeless discharges in the mixtures of a small quantity of a given metallic vapour with some inert gases such as argon or helium This method of excitation being applied to lead vapour led to the experimental proof of the existence of the magnetic dipole radiation.[1]

In the spectrum of tellurium under the same excitation conditions, on a very strong background of Te-bands only faint traces of the 'forbidden' atomic magnetic dipole line λ 5420 were found[2]. In our present experiments the main effort was to increase the dissociation of tellurium molecules. Satisfactory results were obtained when tellurium vapour of the density corresponding to that of the saturated vapour at 350°–400° C was heated to about 900° C The forbidden line λ 5420 A. (${}^3P_1 - {}^1S_0$) appeared even in the case of pure tellurium vapour When argon or helium was admitted to the tellurium vapour the intensity of this line became considerably larger with increasing density of the added gas Two other 'forbidden' Te I lines, λ 4309 A (${}^3P_2 - {}^1S_0$) and λ 7909 A. (${}^1D_2 - {}^1S_0$), were also found. These lines are much weaker as compared with λ 5420 and appear in the mixtures of tellurium vapour with inert gases only, argon being in this respect much more effective than helium.

The accompanying diagram represents the energy levels of the neutral tellurium atom belonging to the same lowest electron configuration $5s^2\,5p^4$. All these energy-levels, except the ground-level ${}^3P_2$, are metastable and no spontaneous transitions between them accompanying the normal electric dipole radiation may occur in accordance to the Laporte selection rule Transitions corresponding to the emission of the obtained 'forbidden' Te I lines are indicated by arrows The measured wave-lengths of those lines are in complete agreement with those calculated from the known values of spectral terms.



The transitions corresponding to these 'forbidden' lines are to be considered as spontaneous ones since the lack of any sufficiently strong external or intermolecular electric fields excludes the possibility of electrically perturbed transitions Taking into account the selection rules for the quantum numbers *J* and *L* for the electric quadrupole and magnetic dipole radiations, the line λ 5420 (${}^3P_1 - {}^1S_0$) is to be regarded as due to the pure magnetic dipole radiation, and the lines λ 4309 (${}^3P_2 - {}^1S_0$) and λ 7909 (${}^1D_2 - {}^1S_0$) as due to the pure electric quadrupole radiation.

A more detailed account of these experiments will be published later

Atomic Absorption Coefficients and Transition Probabilities

THREE recent letters raise the question as to whether there is any experimental basis for applying Kramers' equation for continuous absorption to astrophysical problems[1]. Ditchburn cites the anomalous phenomena shown by alkalis at the absorption series limits as the only direct experimental evidence. A series of papers[2] by me on the emission spectra of cæsium vapour gives direct evidence as to the transition probabilities for the continuous spectra and line spectra of the levels 6 *P* and 5 *D* The first paper indicated that the probability of recombination depended on the pressure but subsequent work showed this to be erroneous, and the last paper (published after the appearance of Ditchburn's letter) shows that the continuous transition probabilities remain nearly constant with electron concentrations ranging from 10^{13} to 10^{16} per cm³ and with pressures from 0·001 mm to 17 mm of mercury

By the principle of detailed balance, the continuous atomic absorption coefficients at the series limits can be derived The values are $3·6 \times 10^{-17}$ at the 6 *P* limit and roughly 3×10^{-17} at the 5 *D* limit while Gaunt's[3] theoretical equation for hydrogen with frequencies effective quantum numbers and weights appropriate to cæsium gives $2·5 \times 10^{-17}$ and $3·7 \times 10^{-17}$ There is no reason to expect exact agreement here

As concerns astrophysical applications the discharge conditions of pressure and electron concentration cover the range of conditions to be expected in stellar atmospheres but not of course, in nebulæ Line transition probabilities in the *F* and *D* series also have nearly hydrogenic values but values for the S series are abnormally low Page has assumed that the intensity of hydrogen emission lines measures the rate at which electrons recombine into the excited states while Menzel suggests that interactions between atoms electrons etc will give a temperature distribution of excited states Experiments on the cæsium discharge show a temperature distribution at pressures above 0·1 mm but not at low pressure It is very desirable to obtain more experimental data on transition probabilities in hydrogen but conclusive experiments require measurement of the concentration of excited or ionized states as well as of the intensity of the radiation

Electrolytic 'Polishing' of Zinc

IT has been pointed out to us by Prof C O Bannister and Mr P G McCarthy, University of Liverpool, that the current/voltage relationships shown by the curve given in our previous communication[1] do not apply to conditions in which the electrical energy is obtained directly from a suitable low tension supply, as distinct from the potentiometer type' of circuit used in our work We have confirmed that with electrolyte and electrodes as previously described, the use of a 12 volt storage battery (with adjustable series resistance) gives a curve precisely similar to that obtained by Hedges[2] for the anodic polarization of zinc in 8 per cent solution of sodium hydroxide Up to a critical value in the neighbourhood of 1 volt, the potential difference across the bath terminals may be progressively increased, with an accompanying rapid increase in current density, as in our original experiments The fall in current density beyond this point, however, is now accompanied by a sudden rise in potential to about 4 volts, no intermediate values being obtainable Polishing of the zinc anode may still be effected, but only at the higher potentials, with simultaneous evolution of oxygen Polishing at lower (controllable) potentials without gas evolution, occurs only under conditions which give rise to the characteristic curve previously recorded, and this, we now find, is dependent on the use of the potentiometer arrangement, the advantages of which, in this type of work, are confirmed

In our original experiments a 60 ohm adjustable rheostat in a 240 volt D C circuit was used as a potentiometer from which the current supplied to the bath was taken Lower tension supplies may however, be employed provided that the potentiometer resistance is reduced accordingly, for example we have obtained precisely similar curves using a 12 volt battery with a 4 ohm potentiometer resistance The criterion is that the resistance of that section of the potentiometer in parallel with the cell shall be small in comparison with the cell resistance

Under these conditions, relatively large increases in cell resistance due to anodic polarization have a negligible effect on the resistance of the joint system and hence on the potential difference across the cell terminals, that is this potential difference is controlled by the particular fraction of the potentiometer resistance in the joint circuit Any increase in cell resistance is accompanied however by an immediate fall in the current (in our experiments this marks the commencement of the polishing range) which thus affords a sensitive indication of changes taking place within the cell On the other hand if the potentiometer tapping resistance is high compared with the cell resistance the potential difference across the terminals is controlled by the cell resistance itself the net result being similar to that which obtains for the low tension source of current with series resistance that is, the arrangement does not permit the cell voltage to be controlled externally throughout the range investigated Using the arrangement previously described the characteristic curve has now been established both for high purity zinc (more than 99·99 per cent zinc) and for zinc containing 1 per cent lead The cathode may be either zinc or copper but should preferably have about ten times the area of the anode

We are indebted to Prof Bannister and Mr McCarthy for directing our attention to the possible alternative current/voltage curve which we have discussed above and also for their concurrence in the publication of this further note

The N'Goureyma Meteoric Iron

A UNIQUE type of meteoric iron fell at N Goureyma French West Africa, on June 15, 1900 It fills the 65th group of Brezina's classification[1], 65 *Breccia like Octahedrite N Goureyma group*, Obzg Molten and drawn out Iron of the Zacatecas group Brezina defined Zacatecas as 64 *Breccia like Octahedrite Zacatecas group*, Obz Octahedral nuggets breccia like with globes of Troilite

N Goureyma was described by E Cohen[2] with excellent photographs of the very remarkable external sculpturing of the iron I desire to refer to Cohen's suggestion, which appears to have been generally accepted that the iron 'in consequence of its very flat form, softened throughout its mass perhaps to the melting point, as it entered the atmosphere' In support of this he adduces "a large number of phenomena which, up to the present, have never been observed in any other iron ' Among these he gives "the fluid arrangement of the troilite—forming an arrangement closely resembling the fluid structure of terrestrial rocks; the lack of an alteration zone; the unusually varied and in part bizarre relief of the anterior surface", etc

I have recently polished and etched a full-sized transverse section of this iron It shows an alteration zone which varies in thickness from up to 2 mm. at the ridges to ½ mm. or less at the hollows of the surface. This alteration zone can be duplicated, for example, in the iron which fell at Rembang, Java, on August 30, 1919, the interior of which is a normal octahedrite. There appears to be no valid reason for the assumption that the internal structure of N'Goureyma is due to softening or melting in its flight through our atmosphere, or for regarding it as an exception to the general rule that such heat effects are confined to a shallow skin and that the interior remains cold during the fall In the case of meteorite craters, as at Henbury[3] and Kaalijärv[4], fragments of the crater meteorites are found remarkably distorted in their internal structure by heat and shock, but this effect is attributed not to friction in the air, but to the momentum of exceptionally large and fast meteorites being sufficient for them to reach the ground with much of their cosmic velocity unimpaired, the sudden stop resulting in a great rise of temperature throughout the mass No such effect is suggested in the case of N'Goureyma.

There remain two possible explanations of the structure of this meteorite. The first, and most probable, is that it is due to plastic flow within a cosmic body approaching planetary dimensions of which the meteorite is a fragment The other is that, in course of its wanderings, an iron of Zacatecas type approached near enough to the sun to be softened and drawn out Such an explanation has been suggested by Dr L J Spencer[5] for the 'metabolite' structure of Murnpeowie, but that meteorite does not show the unique 'drawn-out' structure of N'Goureyma, which it is difficult to visualize as a heat effect in free space.

Formation of Widmanstätten Figures in Meteorites

IN a recent communication[1], Prof. E. A. Owen advances a theory to account for the Widmanstätten figures in meteorites He suggests that the meteorite is heated to a high temperature in its passage through the earth's atmosphere and is then suddenly cooled on coming to rest in the earth and that in consequence a distorted body-centred lattice, in metastable equilibrium at ordinary temperatures, is produced. He supposes further that the Widmanstätten figures grow by "prolonged annealing" at ordinary temperatures in the earth.

It is, however, generally accepted that a meteorite will not be heated appreciably, except near its surface, in the very brief period during which it traverses the earth's atmosphere, most of the heat and liquefied and vaporized portions of the surface being carried off by the air itself. This conclusion rests upon the well-known observation that in an octahedrite it is only near the surface ("the burnt zone") that the Widmanstätten figures are much broken down and confused. The same effect can easily be produced artificially by heating a piece of 'normal' meteoric iron

The most direct evidence for this contention is provided by such meteorites as Cabin Creek and Charlotte. Both of these were seen to fall and, when examined afterwards, both exhibited normal Widmanstätten figures surrounded by the usual burnt zone.

It may, therefore, be concluded that the heating produced by passage through the earth's atmosphere is insufficient to affect the structure of the meteorite beyond a depth which does not generally exceed half an inch, and that the Widmanstätten structure is one which existed in the body before it traversed our atmosphere.

In view of these facts, Prof. Owen's theory appears untenable

We hope shortly to publish the results of some extensive studies of the constituents of meteoric iron which we have made, using thermo-magnetic micrographic and X-ray methods, and to discuss their significance.

Relationship between Household Income and Food Expenditure

SINCE publishing the results of a study of the consumer-demand for milk among 300 poor working class families in Leeds[1], an analysis has been made of data relating to household income and food expenditure collected during investigation. 'Household income' refers to the money the housewife had for housekeeping purposes and not the total earnings of the members of the household. 'Food expenditure represents the expenditure on all foodstuffs, including groceries, meat, vegetables, milk and similar goods

The average household income was £1 16*s*. 11*d* per week, and the average household food expenditure was 19*s*. 1*d*, or 9*s* 9*d*. and 5*s* 1*d*. per head per week respectively. The regression equation connecting income (V) and food expenditure (F) was derived to determine if the relationship between the two factors was linear or curvilinear. The coefficient of income[2] (V^2) was not significant and the equation became

$$F = 0\cdot62V - 3\cdot83.$$

The correlation coefficient R_{FV} was 0 92. Thus there is a close linear interdependence between income and food expenditure among families examined. and on the average for every 1*s*. change in income food expenditure changed 7½*d*. The partial correlation coefficient $R_{FV\cdot XY}$ connecting income (V) with food expenditure (F) after eliminating changes in the number of adults (X) and children (Y) in the families was 0·85, which indicates that in households of constant constitution there is a close relationship between the factors under consideration.

The conclusion drawn from this analysis is that among the families examined a change in income (according to the definition adopted) is reflected by a proportionate change in food expenditure

A Comprehensive Fundamental Electrical Formula

THE equation given by Dr C V Drysdale in NATURE of December 3 presents a useful picture in electrical concepts of the forces acting respectively upon stationary and moving electric charges By incorporating permeability in the term for the velocity of electric wave propagation, he avoids, if he does not annihilate, magnetic notions In the second term of his equation, the force is seen to depend not on the *difference* of the velocities, V and V', of the charges, but on their *product* This suggests that the force is determined by velocities solely with respect to a basic medium There is still hope therefore of immortality for Maxwell and for that "glorious work of fine intelligence", the ether

A Visual Phenomenon

THE interesting visual phenomenon described by Mr Dartnall in NATURE recently[1] was observed by Helmholtz many years ago[2] The effect—the appearance of a purple after image in a patch of light alternating at a frequency just below the critical frequency—no doubt arises from the differential rate of development of after images of different colour, but some observers whom I tested a year or two ago were unable to see the phenomenon at least under conditions when it could be readily observed by myself and others I then found that those who could not see the effect were those who gave a delayed type of recovery curve after light adaptation[3] as recorded by the binocular matching method

The number of observers tested was insufficient to make the correlation absolutely certain, but the relation may prove of further interest in connecting adaptation processes with after image phenomena, and the effect might prove of practical value in distinguishing one type of observer from another

Points from Foregoing Letters

DR N HAMILTON FAIRLEY reports the synthesis of pseudo methæmoglobin from alkaline hæmatin and native serum albumin derived from man and monkeys, and renames the pigment methæmalbumin This pigment has not been found within the blood corpuscles and cannot function as a respiratory pigment It is not excreted by the kidneys, apparently owing to its large molecular size

Injection of magnesium given subcutaneously to hedgehogs in autumn produces, according to Dr Paavo Soumalainen, a cold blooded state similar to hibernation, but also increases the amount of adrenaline and sugar in the blood By injecting insulin at the same time, the formation of excess sugar is prevented and a state almost identical to hibernation is induced

Synthetic vitamin E (*dl* α-tocopherol) in doses of 0 0075 mgm per gm body weight per day protects chicks against encephalomalacia (a deficiency disease brought about by feeding chicks on a special diet), according to experiments by Dr. H Dam, J Glavind, O Bernth and E Hagens

The ability of the serum to counteract the surface tension lowering effect of sodium oleate and similar substances (du Nouy phenomenon) is due, according to Prof D Rubinstein, to the presence of calcium ions and not to proteins, as generally assumed

Experiments carried out by J B Bateman and Dr L. A. Chambers with surface films of egg albumin on dilute hydrochloric acid, with various ratios of wall to surface, show that the drag-effect of the walls which, it was thought, might account for some of the rigidity effects observed does not in fact appreciably influence the force area diagrams

Dr D F Martyn and G H Munro discuss criticisms by Appleton, Farmer and Ratcliffe, and Berkner and Booker, of their former conclusion that the Lorentz 'polarization' term is zero in the ionosphere They advance further experimental facts in support of their point of view

The 'forbidden' lines 5420, 4309 and 7909 A in the Te I spectrum have been obtained by Prof H Niewodniczański and F Lipiński by heating tellurium vapour of suitable concentration to 900° C, especially in presence of argon or helium The measured wave lengths agree with those calculated from the known values of spectral terms

Measurements of transition probabilities in the cæsium discharge for transitions giving rise to the continuous spectrum in the visible region have been made by Dr F L Mohler over a wide range of conditions Values of the transition probabilities and of the continuous absorption coefficients seem to be independent of pressure and electron concentration, and the numerical values are similar to the theoretical values for hydrogen

Dr W H J Vernon and E G Stroud point out that the characteristic current/voltage curve obtained in their process for the anodic 'polishing' of zinc depends on the use of a potentiometer arrangement for the supply of current to the bath A possible alternative form of curve is discussed

Research Items

Recent Discovery and the Upper Palæolithic

Dr Dorothy A E Garrod has pointed out the need for re orientation and revision in the study of the cultures of the Upper Palæolithic in the light of archæological discoveries of the last twelve years, more especially as a result of research outside Europe (*Proc Prehist Soc* N S 4, 1, 1938) The traditional classification based upon evidence mainly French must now give way to a classification based upon the three cultural elements of primary importance manifested in the hand axe industries, flake industries, and blade industries of which the first two run back as far as we can see, while we are beginning to realize that the origin of the third may have to be sought much farther back than we have suspected In Europe the blade industries appear after the extinction of Neanderthal man and the arrival of *Homo sapiens* though in certain areas industries of Mousterian tradition linger on into Upper Palæolithic times Reviewing recent evidence from France Spain Italy, North and South Germany, Moravia Rumania, South Russia Transcaucasia Palestine, Egypt North Africa and Africa as a whole, a theoretical picture is presented in which the Chatelperronian the earliest identifiable phylum of the blade cultures, emerges in some as yet unidentified centre in Lower Palæolithic times Ultimately it sends out two branches one to East Africa and one to north east Europe, which develops into the Gravettian Meanwhile another stock, the Aurignacian, pushes westward and separates into two great provinces From the Aurignacian and Gravettian centres, migration moves into central and eastern Europe along the southern edge of the ice sheet, until at the extreme limit of this journey we get the characteristic French sequence At the close of the Pleistocene, migration on a large scale comes to an end, and numerous local variations grow up all over the palæolithic world

Iron Deficiency in Pregnant Rats

H L Alt (*Amer J Dis Child*, 56, 975, 1938) made a study of female albino rats which were fed with an exclusive diet of whole milk powder and subjected to one or two pregnancies He found that a single pregnancy did not cause anæmia but resulted in a marked depletion of the iron content of the liver, while a second pregnancy caused moderate anæmia due to deficiency in iron The first litter of female rats with mild iron deficiency had normal hæmoglobin values at birth, but there was a considerable reduction in the total iron content The second litter of rats on a diet deficient in iron showed a decrease in the hæmoglobin content of the blood at birth, and the total iron content of these animals was reduced to one fourth the normal On the other hand, supplements of iron to the milk powder diet completely protected the mother and offspring against iron deficiency

Vitamin C in Pregnancy and Lactation

H M Teel, B S Burke and R Draper (*Amer J Dis Child*, 56, 1004, 1938) have found that the amount of ascorbic acid in plasma from the umbilical cord blood of infants at birth was two to four or more times greater than that in maternal plasma taken at the time of delivery, and that plasma from the umbilical vein contained slightly more ascorbic acid than that from the umbilical artery They have come to the conclusion that the maternal need for vitamin C was considerably increased during pregnancy and that the fœtus *in utero* acted parasitically on the mother as regards vitamin C T H Ingalls R Draper and H M Teel (*ibid*, 1011) made a study of the vitamin C content of the breast milk and of maternal and infant blood plasma during the nursing period, with the following results Fresh breast milk from mothers on the usual diet of a maternity ward contained an average of 4 5 mgm of ascorbic acid per 100 c c during the first two weeks of lactation and the breast fed babies of such mothers received an average of 28 mgm of ascorbic acid daily When a liberal amount of vitamin C was added to the mother s diet, the ascorbic acid content of the breast milk increased to 7 3 mgm per 100 c c, and the babies of such mothers received an average of 46 mgm of ascorbic acid daily The breast milk of mothers who sold their excess supply contained an average of 3 7 mgm of ascorbic acid which decreased to 0 3 mgm after pasteurization and marketing so that the infant fed on pasteurized human milk received an inadequate supply of vitamin C unless he was given an additional amount of the vitamin

Development of the Vertebrate Head

Edward Phelps Allis Jun, is well known to morphologists for his researches, extending over many years, on the structure of the vertebrate head, and he now sets forth his views on the development of the prechordal portion (*J Anat*, July 1938) His article includes a consideration of the Plagiostomi Holocephali, Cyclostomata, and Ganoidei, and proposes to consider the Teleostei Dipnoi and Amphibia It is suggested that possibly in all vertebrates the polar cartilage is the pharyngeal element of the mandibular branchial bar, while the trabecular and palatine cartilages are the dorsal and ventral halves of the premandibular branchial bar which develops in the mandibular process In the chondrocranium the ethmoidal region is in the main derived from premandibular branchial rays The septum nasi in the Elasmobranchs always contains a cavity which is the ventral part of the embryonic cavum internasale The hypophysis is developed in relation to a fold actual or implicit that lies approximately between the cranial and visceral ectodermal surfaces The internal opening of the fold lies opposite the hind end of the infundibulum, and the external opening lies opposite the pre optic recess

A Population Study of an Australian Earth Mite

Pamphlet No 84 of the Australian Council for Scientific and Industrial Research has recently been issued under the title "A Population Study of the Red legged Earth Mite (*Halotydeus destructor*) in Western Australia', by Mr K R Norris The mite is a notable pest of clover pastures in the west While it can be controlled on a small scale, as, for example in market gardens, by spraying, this method cannot be applied economically on grazing land Here help must be sought chiefly from methods of altering the environment of the mite, such as by changing the composition of the pasture, or by introducing a natural enemy The foundation for work of this type is an accurate knowledge of the relationship of the mite to its environment, and of the conditions which influence its abundance Appreciating this position, the University of Western Australia appointed two Hackett students to make a careful study of the biology of the pest The present pamphlet constitutes the results of the field investigations which were carried out The work is now being continued by the Council, which is being assisted by a committee representative of the University of Western Australia, the Department of Agriculture of Western Australia, and of itself Mr Norris shows that three generations of the mite occur during a year at Guildford, Western Australia It does not occur during the summer, but pastures are attacked in the autumn, winter and spring, especially severe damage being done in the first named season The mites are carried over the summer in the egg stage In the search for limiting factors which influence the abundance or scarcity of the mite, very few have been found to be of direct significance The mite appears, *in fact*, to be limited in the main by the amount of vegetation available—predators and parasites, it seems, play little or no part at all

Apple Storage

THE work of Kidd and West has demonstrated that it is bad practice to store apples of differing degrees of ripeness in the same store, since the ethylene produced by ripe fruit shortens the storage life of unripe fruit The same authors have now shown (*J Pomol and Hort Sci*, 16, 274, 1938) that lenticel spots may be produced on apples of a given variety by storing with ripe fruit of a different variety Similar lots of Bramley's Seedling, Edward VII, or Laxton's Superb apples in the pre climacteric condition were placed in store on October 4 with either Worcester Pearmain or James Grieve fruits The latter varieties were yellow, ripe and greasy and definitely past the climacteric peak Gas mixtures of either (*a*) air or (*b*) 10 per cent carbon dioxide, 10 per cent oxygen and 80 per cent nitrogen were passed through the chambers Control chambers contained the ripe and unripe fruits stored separately. When the fruits were examined on January 31, severe lenticel spotting had occurred on the Laxton's and Bramley's stored with the ripe varieties, but no spotting occurred on the Edward s nor on the now over ripe Worcester's and Grieve's Identical spotting was produced on gas stored Bramley s and Laxton's by adding 1 part in 500 of ethylene to the storage atmosphere for three weeks Ethylene also hastened the ripening of the gas stored fruits, but the ripe Worcester's and Grieve's had no such effect It is suggested that the concentration of ethylene produced by the ripe fruit was lower than that of the pure ethylene added, whilst a further possibility is that the ripe apples produced a volatile substance which delayed ripening

Earthquake in the East Indies

IN co-operation with Science Service and the Jesuit Seismological Association, the U S Coast and Geodetic Survey have made a preliminary determination of the epicentre of the earthquake of October 20 from records received at Fordham, Honolulu, Georgetown, Weston, San Juan, Apia, College (Alaska), Phu Lien, Manila, Pasadena, Chicago, Burlington, Philadelphia and Euancayo The epicentre is determined provisionally as near lat 10° S, long 123° E This is just to the north of the Island of Rotti, in the Suva Sea, and a little to the west of south of the epicentre of October 10 The time of origin of the later shock is estimated to be 2h 19 3m G C T, and the depth of focus normal No damage has been reported from this part of the world though this is probably because the epicentre was submarine and the nearest land very sparsely inhabited

Gas Works Effluents and Ammonia

IN the past, Great Britain has suffered greatly in loss of amenities and beauty of landscape from want of forethought in the disposal of trade wastes and liquid and gaseous effluents Industrialists have been too ready to assume, and the State and the public too ready to concede, the impossibility of preventing or remedying a nuisance arising from manufacturing processes Each industry should be expected to take every possible step to prevent its operations from becoming a nuisance Dr Key s recent book ('Gas Works Effluents and Ammonia", Institution of Gas Engineers, pp 150, 5s net) records how the British gas industry has faced just such a problem In 1926, on the initiative of the president, Mr C F Botley, the Institution of Gas Engineers began a study of the problem of disposing of ammoniacal liquor and the effluent resulting from its treatment This problem had been rendered more acute by the fall in the value of ammonia and the change in the composition of gas liquor following changes in the process of gas manufacture The Research Committees of the Institution have spent £13,000, and many gas undertakings have in addition spent large sums The results have been brought together in this book and show that the problem is by no means so formidable as was supposed, provided that rational and scientific control is applied in practice Dr Key s work touches upon all aspects It gives in a concise form just the information which the practical man will need and will certainly find a welcome wherever coal is carbonized It records an example which other industries might well follow

Production of Negative Ions

THE production of negative ions by the impact of positive ions on metal surfaces has been observed It has been suggested that positive ions may capture two electrons from the metal R H Sloane and R Press (*Proc Roy Soc*, A, 168 284; 1938) have investigated the positive ions produced by bombardment of the negative electrodes in a hot cathode discharge in mercury vapour The ions were analysed in a magnetic field and found to be mainly the relatively light ions CO^-, $C_2H_2^-$ They are probably formed by the sputtering of occluded films The ions apparently leave the metal with appreciable velocities, since they have energies greater than could be imparted to them in the electric field Special experiments were done to eliminate the possibility that these energies were acquired from unsuspected electrical oscillations In further experiments, a double mass spectrograph was set up, a metal plate was bombarded with known ions (Hg^+ Hg^{++}) and the negative ions emitted were analysed and found to be CO^-, $C_2H_2^-$ There seems to be no doubt that a metal surface bombarded by ions of one kind can emit ions of another kind The existence of the Hg^- ion, formed by electron capture, seems to be still in doubt

Transition Stages between Order and Disorder in Condensed Phases

ONE necessary stage in the learning of physical chemistry is that in which the crystalline state is represented as one of perfect order—one molecule to each lattice point only disturbed by the thermal motion a quivering of the structure as a whole—and the liquid and gaseous states as entirely disorderly the equation of van der Waals being used to demonstrate that a disorderly assembly of molecules can undergo a two phase condensation This was the stage which the education of physical chemists as a whole had reached a few years ago but now the gradual accumulation of new knowledge about the detailed molecular structure of condensed matter is forcing us to learn lessons of which such pioneers as Boltzmann and Mie were in principle aware by the turn of the century They had perceived already in particular from specific heats and densities that molecules in a liquid must undergo very much the same motions as in the solid state Now we are learning that there may be a great deal of order in the liquid and a great deal of disorder in the crystalline state, and it is even by no means so obvious as once it seemed that liquid and crystalline solid *must* form two sharply distinct phases

This is the state of knowledge which makes most opportune the German Bunsen Society's second discussion meeting which was organized by Prof C Wagner at Darmstadt on October 28 29 The main purpose which this meeting served was to bring together very fully and systematically all the methods by which the molecular structure of condensed matter can be investigated and the results in respect of departure from the crude classical picture which have been obtained

Any of the following sorts of disorder may occur in the crystal (1) unlike atoms especially if not *too* unlike can exchange places, (2) lattice spaces may be unoccupied, (3) molecules (atoms, ions) may be present at wrong sites (interlattice spaces), (4) molecules or ionic groups may be wrongly oriented or may rotate

(1) is a common occurrence in alloys In such cases for example β brass there is at low temperatures a superlattice of orderly alternation of copper and zinc atoms which becomes increasingly disordered on heating and finally vanishes in a transition of second order to a random distribution while the ground structure, disregarding the differences between copper and zinc atoms remains substantially unaltered Borelius brought together a great deal of experimental data on these place change transitions in alloys which have aroused revived interest since Bragg and Williams offered an explanation of them The basic principle of this explanation is that a small amount of disorder weakens the potential maintaining the structure so that each further step towards increasing disorder becomes easier and easier, a fact which reveals itself in a continuously accelerating rate of change with rising temperature, and a high and rising specific heat which drops abruptly when the disorder is completed This is known as a co-operative change

A number of very sensitive optical electrical, and photo electric methods of investigating small amounts of disorder in ionic crystals have been developed by Pohl and his collaborators one of these the measurement of electrolytic conductivity in the solid has been recently applied by Wagner to give quantitative determinations of the disorder present following a theoretical attack on the problem in conjunction with Schottky This is particularly sensitive to (2) a vacant ionic space behaves as a mobile ion of the opposite charge To obtain additional information he purposely produces vacancies by adding impurity of another ionic type for example $CdCl_2$ to AgCl Vacant spaces may be formed spontaneously in something like vapour concentration ions of both signs being missing in greater concentration as the accompaniment of (3) that is when some ions are displaced in the crystal in almost any concentration when impurities of another ionic type are added or when ions of variable valency are present or finally in stoichiometric amount when the numbers of lattice points for cations and anions is not in the same ratio as the numbers of ions Usually the large anions form a substantially perfect simple lattice while the cations form a more disordered one in the interstices For example in silver bromide the bromine ions form a cubical close packed lattice At room temperature all but about one in a thousand of the silver ions occupy a similar lattice in the octahedral interstices of this one but by 400° C (the melting point is 416° C) no less than 16 per cent of them are displaced into the smaller tetrahedral interstices α AgI provides a more extreme case in this the anions form a looser body centred cubic structure and the silver ions are distributed practically at random over forty two possible sites in each unit cell—in fact they may well be regarded as forming a positively charged liquid permeating the anionic crystal, and they give rise to a very large electrolytic conductivity which is practically unaffected when the crystal melts Such gross disorder as the latter is of course accessible to X ray investigation, and this method has produced a multiplicity of examples, much more complex than these simple ones and of a variety which would soon have become overwhelming without the newly devised systematic classification used by Laves in reporting on this field

Following these two accounts of experimental results, their theoretical background in statistical mechanics was painted in by Schottky, with his usual meticulous attention to fundamental detail But even so there remain many difficulties to be disposed of in this complex field of theory Schottky and Laves suggested that a complete description can be given in terms of the extent of occupation of a number of interpenetrating partial lattices, but Debye in discussion indicated that it is also necessary to consider how the occupation of any particular point in one partial lattice influences the probability of occupation of neighbouring points in that and others This is of course implicit in the theory of co operative changes, which Schottky presented in Kirkwood's approximation

After these sorts of disorder characteristic of rystals composed of monatomic elementary particles we come to another, (4) above, which only enters where independent covalently bound groups of atoms are present here we find a characteristic group of phenomena which may be confidently attributed to rotation or not fully determinate orientation of those groups within the crystal Where polar molecules are present we find large dielectric constants Pauling predicted this for HCl in 1930, and its confirmation enforced the acceptance of a hypothesis which had been received very sceptically when first proposed by Simon to account for specific heat anomalies, but it was certainly a shock to all preconceived notions when Yager and Morgan found that the dielectric constant of molten camphor does not alter when it freezes only dropping to a low value in a transition 120° below the melting point in spite of the size and rigidity of the molecule In many cases we find specific heats considerably exceeding the values of similar monatomic substances (for example NH_4Cl compared with NaCl) The onset of rotation as temperature rises is commonly marked by a range over which the specific heat rises o very large values to produce a λ point transition —this is the characteristic sign of a co operative ffect it means that the rotation of a few molecules reduces the potential hindering the rotation of others and the theory of it is essentially the same as that of the co operative place change transitions in alloys

The word rotation, incidentally, should be interpreted rather cautiously for in many respects the same properties result if each molecule has a choice between two or more possible orientations The actual extent to which the rotation is hindered must vary very widely from case to case For polar molecules it can be actually determined when dielectric dispersion or absorption is observed, and may be declared to be low when it is not Rough estimates can also be made from the specific heat urves, if the necessary data to reduce these to constant volume are available Usually they are not, nd to meet this Eucken made bold use of empirical rules in preparing what was in the outcome a very instructive review of the changes in specific heat which accompany rotational transitions It may e presumed that the empirical rules are least reliable recisely in the interesting regions where there are arge co operative structural contributions to the pecific heat, but this does not weaken the conclusion that in many cases something like free rotation is ttained The X ray method is unable to give much nformation for the smaller molecules with only one eavy atom, but reveals rotation of paraffin chains s Pauling pointed out in his first paper on this ubject, and has recently been applied by Hassel o cyclo hexanol and its derivatives It will be interesting to see the result of an X ray study of amphor

The discussion of disorder arising in the crystal was completed by Gerlach s report on the ferro magnetic Curie point, the prototype of co operative second order transformations, and a brief account sent by Scherrer of the behaviour of Rochelle salt, its dielectric analogue

The rest of the discussion was devoted to the complementary case of the order which is present in substances which are not crystals, that is, in liquids, rystalline liquids, glasses and rubber Debye was hiefly concerned to explain all the known lines of ttack by which we can discover the extent of the quasi crystalline structure present in liquids The specific heat at constant volume of monatomic liquids indicates that the atoms possess considerable potential energy not very different from that in the solid The fine structure of the Rayleigh line in scattered light reveals the same Light is only scattered from irregularities of density in the body having the same scale as its wave length Hence the molecular structure has no influence but the scattering irregularities are thos produced by the thermal motion In a crystal it is known that the close coupling of the motions of neighbouring molecules causes these motions to take the form of trains of sound waves and the observed scattered light is reflected from these wave trains according to the Bragg reflection law A doublet structure results as a Doppler effect from wave trains going in opposite directions It was at one time supposed that the liquid gave a triplet structure owing to its intermediary state between gas and crystal but it appears that this is only a secondary result of the large difference between C_p and C_v in most liquids in water at 4° Ramm found only a doublet There is however an appreciable broadening of the component lines which as Zernike remarked indicates that the wave trains are shorter in the liquid, showing higher damping

The damping of supersonic waves in liquids can be directly measured and is found to be much larger than can be explained by the viscosity and thermal conduction It can be explained if part of the compressibility of the liquid involves molecular rearrangement having a relaxation time of the order of magnitude 10^{-10} sec This method has not been properly exploited yet The newest and best method of measurement again uses the diffraction of light in this case from artificially produced wave trains

To find the structure on a molecular scale we must use radiations of much shorter wave length The blurred rings in the X ray diffraction pattern of liquids discovered by Debye and Scherrer and given their full interpretation by Prins and Zernike tell us the average value of the product $\delta_1 \delta_2$ for any desired value of r, where δ_1 and δ_2 are the deviations from the average electron density at any two points a distance r apart from one another Though this does not suffice to give us a complete unambiguous picture of the structure, it tells us a great deal about it and allows us to reject false proposals We find that the arrangement of atoms in liquid mercury is more nearly crystalline than random rather like a bag of marbles and that long shaped molecules favour parallel positions, like a bag of nails Along any line drawn in imagination through the substance we shall find a regular fluctuation in density, with much the average amplitude and period in the liquid as in the crystal the great difference is that this periodic fluctuation is coherent over great distances in the crystal, but only over short distances in the liquid

When dipole molecules are present, we can again use the dielectric properties to gain information about the freedom of orientation of molecules the dielectric constant of a dipole liquid is often much less than it would be if the molecules exerted no influence on each other s orientation Although the Debye theory of hindering potential is doubtless not general enough, and must give place to some such description as Onsager s, it directed attention to this source of information and provided the first quantitative treatment sufficient to rule out any suggestion that the molecules in a liquid rotate freely, unhindered by their neighbours The structure is quasi crystalline with regard to orientation as well as to translation

In the concluding reports Kast dealt with anisotropic liquids, Jenckel with glasses and Wittstadt with rubber The transformation of such a liquid as *p* azoxyanisole to the nematic state, at which we know from the optical properties that some 30 per cent of the rod shaped molecules suddenly become roughly parallel to one another over fairly wide regions while the X ray scattering diagram scarcely alters and the fluidity actually increases, is probably one of the simplest of all transitions of a quasi crystalline to a crystalline state Kast s presentation of the facts was very favourable to Frank s theoretical description of the change Jenckel concerned himself mainly with the transformation point of glasses This is the temperature at which the viscosity becomes so high (about 10^{13}) that molecular rearrangement no longer takes place in times compatible with human patience Below this temperature the coefficient of expansion and the specific heat are much smaller It is chiefly interesting in the present connexion for showing that molecular rearrangement in the liquid contributes largely to these properties above that temperature Rubber provides a superb example of the way in which the various lines of attack described above, thermal, Röntgenographic dielectric and statistical mechanical, have been applied to the elucidation of a peculiarly complex case The presence together of Kuhn, Meyer and Thiessen ensured a lively discussion

Prof Wagner and the Bunsen Gesellschaft are to be congratulated on the success of this, the second *Diskussionstagung* which it has organized after the Faraday Society model, circulating all main contributions in full beforehand F C FRANK

Science and the Army

AT the Science Museum, South Kensington, there has been arranged a special War Office Exhibition which for a period of three months, gives visitors an opportunity of acquainting themselves with the numerous points at which science comes into contact with the work of the British Army It will probably surprise many to learn that, at the several training centres for boys who enter at fourteen years of age, technical instruction, both practical and theoretical, is given which compares favourably with that obtained by the average apprentice in civil life At the Military College of Science, Woolwich this reaches its highest development in the training for the grade of artificer, Royal Artillery, the course for which extends over five years and produces men of high technical skill Mechanization accounts for a great increase in the engineering requirements of Army services, and the extent of this will be realized from the exhibits showing the preparations for the driving and maintenance of transport vehicles and tanks and for the repairs carried out in the heavy workshops operated by the Royal Engineers and Royal Army Service Corps The high stage of development reached in the signals and wireless services is demonstrated and here, to a large extent, the apparatus has to be specially designed for the conditions of use in the field, though, so far as possible, commercial forms are adopted

In certain branches, it will be seen that the Army has been leading the way, and this is notably the case in the making of maps The exhibit shows that the War Office, breaking away from the Continental practice, has developed a comparatively simple method of aerial surveying, and the various stages of making the types of maps which can be produced in the field are illustrated The manifold services of the Royal Engineers can be seen in exhibits of different kinds of bridges made and used in war, and in examples of demolitions, water supply arrangements with well sinking and distribution, and such work as the drainage schemes carried out in conjunction with Royal Army Medical Corps anti-malarial measures at places like Singapore Medical science is represented by models of field disinfectors, water purifiers and the latest type of small cooker for use in tanks

In the Air Defence Section some highly scientific exhibits are to be seen The sound locator is based on the principle of human hearing whereby when waves of sound reach the ear, the head is turned until they come equally to each ear So, the locator is turned until its trumpets, one pair for bearing and one pair for elevation, give the position of the source of the sound The Vickers predictor is, in a like sense, a pair of mechanical eyes In addition to ranging its target, it gives the bearing, the elevation and the right fuse setting making allowance for trajectory curve, wind, and even for variation in barometric pressure in the upper air Its information is transmitted electrically to dials on the guns, and all that the men on the gun have to do is to keep mechanical pointers in line with the electrical pointers

Research in Army matters is much more coordinated than it is in civil affairs Development in one direction has immediate repercussions in others —if, for example, a gun of higher rate of fire is visualized, questions as to ammunition, supplies and possibly man power will have to be dealt with—and consequently the research organization is very broadly based as the exhibition will show A most interesting exhibit is the R D Camera which films shells as they are actually fired The Ballistic Section also shows the Brown Hall photographic lorry which enables this filming to be done in the field and the cascade thyratron which measures bullet velocities when 'bursts' are fired The Chemical Research Branch at Porton and the Experimental Establishment at Biggin Hill are also represented, and this section of the Exhibition conveys an impression of the unceasing scientific inquiry that is conducted by the War Office to ensure that the highest efficiency of man and material may be attained in the requirements of the Service

Carnegie Institution of Washington

Dedication of Elihu Root Hall

TO foster its programme for the interpretation of scientific research, the Carnegie Institution of Washington dedicated, on December 8 last a new wing for its administrative building in Washington The new wing contains a beautiful auditorium, seating nearly 500 people and also exhibition halls and additional offices

Mr Elihu Root, former Secretary of State Secretary of War and United States Senator, who from 1902 until his death in 1937 served as a member and later as chairman of the Board of Trustees of the Institution, was the directing head of the movement to provide funds for the erection of the new wing and the new hall has been named after him

Dr John C Merriam president of the Carnegie Institution of Washington who is retiring on December 31 after eighteen years of service, in introducing Sir Richard Gregory to deliver the Elihu Root Lecture on Cultural Contacts of Science" (see NATURE of December 17 p 1059), said that the dedication of the Hall marked the realization of a plan which had been in the mind of Mr Root and before the Board for many years, as furnishing the possibility of better interpretation of researches conducted by the Institution "This very beautiful auditorium furnishes an unusual environment favourable for presentation of statements concerning research or for discussion of critical problems touching science Assuming that the programme of Carnegie Institution of Washington will maintain a pace comparable to that of past years, we may expect future decades to note the continuing importance of this auditorium as a place from which there will be an increasingly significant diffusion of knowledge on subjects relating to science and research

The most striking features of the Elihu Root Hall are the two huge murals which fill the entire sides of the auditorium and depict heroic figures contemplating the world, figures which symbolize the research workers of the Institution surveying the fields of fundamental research On one wall is the Atlantic Ocean and on the other, the Pacific By ingenious use of perspective the scenes give the illusion of standing on a high mountain top and looking out over whole continents and oceans

Notable, too, is the ceiling of the hall, containing large transparencies of the sun and of the moon in eight of its phases That of the sun represents a combination of two photographs taken with the spectroheliograph, one of the disk in calcium light and showing sunspots, and the other of the limbs in hydrogen light and showing numerous prominences Those of the moon are reproductions of photographs made at the Newtonian focus of the great 100 inch telescope at Mt Wilson Observatory

The acoustics of the hall have been specially designed to incorporate the latest advances in reducing reverberation and in ensuring the optimum acoustical conditions for human hearing The architect for the new wing and auditorium was Mr William A Delano, and Mr J Monroe Hewlett painted the murals on the walls of the auditorium

The opening of the Elihu Root Hall with its exhibition galleries and offices marks a stage in the development of the two fold purpose of the Carnegie Institution, namely, the development of natural knowledge by research and its interpretation to as wide a public as possible The Institution maintains a staff of research workers in Washington and in the field, who present reports from time to time of their work These reports take the form of papers presented and discussed at conferences and the trustees of the Institution provide annually for the printing and distribution of such reports to the principal libraries of the world where the information they contain is available to all who desire it Thirty seven Year Books comprising sixteen thousand pages of summary reports of work in progress seven hundred and twenty eight monographs aggregating more than two hundred thousand pages and eleven thousand five hundred papers, represents a mass of scientific data prepared by the specialist for the specialist reader

The other side of the Institution's activities is occupied with the interpretation of these data and the explanation of their significance to the non technical citizen This problem has been approached in various ways through the schools the press the exhibition hall the lecture platform the radio and the cinematograph Simply written articles on current advances are prepared and distributed as separates to schools of the secondary type, and bound volumes of such separates are prepared for their libraries Suitable articles for newspaper use are also sent out as well as short notes of news character The annual exhibitions, consisting of exhibits arranged and demonstrated by the research workers responsible for the investigations illustrated, bring home even more vividly to those able to visit them the significance of recent developments

The public lectures provided by the Institution consist of two distinct series One of these series is given during the winter and spring months by the members of the staff of the Institution, who deliver general lectures on the progress of investigation in their own particular fields The other series was established in memory of Mr Elihu Root, who was much interested in the idea of arranging special lectures upon the influence of science and research upon current thought The intention of these lectures is to direct attention not only to the development of science but also to its deeper meaning for life and civilization, and to this end leading thinkers of international repute are invited to Washington to deliver their message

In addition to these formal lectures, the staff of the Institution frequently give lectures to local scientific and other interested bodies

The Carnegie Institution of Washington, through its research workers, is contributing substantially to the sum of human knowledge and is also providing for the presentation and preservation of the records of their labours Further, the Institution has attacked, with marked success, the equally important problem of conveying the import of current scientific developments to a wider public, on the knowledge and understanding of whom depends the future of civilization itself

Science News a Century Ago

Ancient Carthage

THE *Gentleman's Magazine* of December 1838 contains the following information: "Sir Grenville Temple has employed himself for the last six months in making excavations on the classic soil of Carthage. On the site of the temple of Ganath, or Juno Coelestis, the great protecting divinity of Carthage, he found about seven hundred coins and various objects of glass and earthenware. But the most remarkable and least expected of his discoveries is that of a villa, situated on the seashore, and buried fifteen feet under the ground. Eight rooms have been completely cleared, and their size and decorations proved that the house belonged to a wealthy personage. The walls are painted, and the floors beautifully paved with mosaic, in the same manner as those at Pompeii and Herculaneum, representing a great variety of subjects, such as marine deities, both male and female, different species of sea-fish, marine plants, a vessel with female figures dancing on the deck, and surrounded by admiring warriors, other portions representing lions, horses, leopards, tigers, deer, zebras, bears, gazelles, hares, ducks, herons, etc. Ten human skeletons were found in the different chambers. In another house are mosaics, representing gladiators contending in the arena with wild beasts, and over each man is written his name. In another part are seen horse races and men breaking in young horses."

The Asiatic Society

ON January 5, 1839, a communication by Lieut. James Raymond Wellsted (1805–42) of the Indian Navy was read relating to the identity of the Himyaritic writing and the dialect of Job with that still spoken by the inhabitants of Mahrah. In his letter, Wellsted described his discovery of inscriptions in the south of Arabia and gave his reasons for supposing they contained the ancient Himyaritic language. The great Himyaritic Empire is said by Arabian historians to have lasted about 2,000 years and to have extended its limits to India. Many persons had doubted the existence of this empire, but recent discoveries had shown that it had been the seat of large and populous cities. Wellsted also referred to the discoveries of Mr. Cruttenden, at Sana, similar to those which he himself made, and concluded with the hope that other officers of the Indian Navy would endeavour to add to our knowledge of those parts. He was able to state that the newly appointed governor of Bombay, Sir James Revett Carnac, would further their efforts.

Flora of the London District

AT a meeting of the Botanical Society on January 4, 1839, the curator, Mr. Daniel Cooper, read a paper entitled "Remarks on the Dispersion of Plants in the Environs of London, and the Formation of Plans Exhibiting the Distribution of Species over Localities". The Metropolitan botanist, he said, can certainly boast of a flora, perhaps not to be equalled throughout the whole of England. Surrey is particularly rich in orchidaceous plants; twenty six out of the thirty six species are found dispersed within thirty miles of London. In Kent, it may be observed that the species are not quite as abundant, in the ratio of twenty one to thirty six, including two species which had not, to Mr. Cooper's knowledge, been found in Surrey, at least within the range before specified by *Ophrys fucifera* and *Ophrys tetrophos anthos*. This tribe is not confined to the counties of Surrey and Kent in the London district as might be supposed; they occur also in Essex and Middlesex, but not so frequently.

The *Athenæum* and Steam Navigation

THE *Athenæum*, in its first issue of January 1839 again dwelt at length on the subject of steam navigation, the article being prompted by the appearance of various publications relating to steam navigation to India and across the Atlantic. "With these, and many similar documents before us," the writer of the article said, "and standing as we do on the threshold of a new year, the prospects which open to us are of an extraordinary character, to which in the retrospect of the past, we can find no parallel. Steam navigation, hitherto in its infancy, is now rapidly advancing to gigantic maturity; and the future achievements of the infant Hercules may readily and safely be predicted from the growing feats of the athletic youth. It is manifest that this globe of ocean and earth is about to be enclosed in a continuous network of communications by steam. In this development Great Britain must necessarily for a long period of time be the principal instrument of extending and maintaining this gigantic system of communication. She alone possesses the requisite machinery, workshops, artificers, enterprise, public spirits and capital for so stupendous an undertaking."

Having thus approached his subject, the writer then went on in a well informed manner to the design of ships, their size, their subdivision, materials for them and improvements in machinery. Large vessels were, he said, safer, surer and drier, while facility of construction, economy and strength made iron construction desirable.

University Events

LONDON.—The title of reader in the University has been conferred on the following in respect of posts held at University College: Mr. C. R. Bailey (chemistry), Dr. R. O. Buchanan (economic geography).

The degree of D.Sc. has been conferred on Mr. T. G. Pearson, an internal student of the Imperial College (Royal College of Science).

The William Henry Hudson Memorial Prize has been awarded for 1938 to Miss Margaret E. Willy, of the New Cross Goldsmiths' College Centre.

The Graham scholarship in pathology has been awarded to Mr. R. M. Calder.

OXFORD.—In Congregation on December 10, the honorary degree of D.Sc. was conferred on Dr. Irving Langmuir, director of the Research Laboratories of the General Electric Company of the United States.

Dr. W. Hume Rothery, formerly senior demy of Magdalen College, has been elected to a fellowship.

Forthcoming Events

Friday January 6

Institution of Mechanical Engineers at 6 —H Scott Paine Some of the Aspects and Problems of the Development of High Speed Craft and its Machinery (Thomas Lowe Gray Lecture)

Mathematical Association January 2–3 Annual Meeting to be held in King s College London

January 2 —W Hope Jones Simplicity and Truthfulness in Mathematics (Presidential Address)

Physical Society January 3–5 Annual Exhibition to be held at the Imperial College of Science and Technology

January 3 —Dr J D Cockcroft F R S The Cyclotron and its Applications

January 4 —C S Wright Geophysical Research in Polar Regions

Science Masters Association January 3–6 Annual Meeting at Cambridge

January 3 —Prof J Gray F R S The Role of Science in Education (Presidential Address)

Geographical Association January 3–6 Annual Conference to be held in the London School of Economics

January 3 —Sir Thomas Holland F R S The Geography of Minerals (Presidential Address)

Institute of British Geographers, January 5–6 Annual Meeting to be held in the London School of Economics Houghton Street W C 1

Appointments Vacant

Applications are invited for the following appointments on or before the dates mentioned

Junior Scientific Officer in the Forest Products Research Laboratory—The Establishment Officer Department of Scientific and Industrial Research, 16 Old Queen Street Westminster S W 1 (Ref J 39 1 January 10)

Assistant Lecturer in Zoology in King s College London—The Secretary (January 1)
